GEOGRAPHIC DISTRIBUTION

Instructions for contributors to Geographic Distribution appear in Volume 37, Number 1 (March 2006). Please note that the responsibility for checking literature for previously documented range extensions lies with authors. Do not submit range extension reports unless a thorough literature review has been completed.

CAUDATA

AMBYSTOMA JEFFERSONIANUM (Jefferson Salamander). USA: PENNSYLVANIA: Chester Co.: Pond on St. Peters Rd. near intersection with Wells Rd. (40°12.78'N, 75°43.75'W). 14 February and 20, 23, 27 March 2005. Nadine Bergeron and Helen Brower of the Amphibian Preservation Alliance (bshiningwoman@hotmail.com). Verified by Ned Gilmore. Academy of Natural Sciences (ANSP 36020). Two adults were observed crossing the road 14 February and 20 adults on 20 March. 17 adults were observed crossing the road in the opposite direction on 23 March and 27 adults on 27 March. Two adults were observed in 2003, nine in 2004, and seven in 2006 at the same location. Extends range of species in southeastern Pennsylvania (Hulse et al. 2001. Amphibians and Reptiles of Pennsylvania and the Northeast. Cornell University Press, Ithaca, New York. 419 pp.).

Submitted by **MAC F. GIVEN**, Neumann College, Aston, Pennsylvania 19014, USA; e-mail: mgiven@neumann.edu.

AMBYSTOMA MACULATUM (Spotted Salamander). USA: ARKANSAS: Lincoln Co.: Wooded area 3.2 km SW of Star City (Sec. 13, T9S, R8W). 15 April 2006. Henry W. Robison. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 30135). Verified by Stanley E.Trauth. New county record in southeastern Arkansas (Trauth et al. 2004. Amphibians and Reptiles of Arkansas. Univ. of Arkansas Press. Fayetteville).

Submitted by **HENRY W. ROBISON**, Department of Biological Sciences, Southern Arkansas University, Magnolia, Arkansas 71754-9354, USA; e-mail: hwrobison@saumag.edu.

AMBYSTOMA MACULATUM (Spotted Salamander). USA: ILLINOIS: Franklin Co.: Fitzgerrell Park road within Wayne Fitzgerrell State Park. GPS coordinates are as follows: N 0329676m and W 4218592m, zone 16 using NAD27 CONUS map datum in UTMs. 9 March 2006. Chad R. Dolan and James T. Lamer, Illinois Natural History Survey (INHS 20029). Verified by Chris Phillips, Illinois Natural History Survey. First county record (Phillips et al. 1999. Field Guide to Amphibians and Reptiles of Illinois). The salamander was caught by hand, on the road during heavy rainfall, air temperature of 13.9°C. This was the only *Ambystoma maculatum* observed, however, three Tiger Salamanders (*A. tigrinum*) were also collected from this road.

Submitted by **CHAD R. DOLAN, JAMES T. LAMER,** and **JOHN K. TUCKER,** Illinois Natural History Survey, 8450 Montclair Ave, Brighton, Illinois 62012, USA.

AMBYSTOMA MACULATUM (Spotted Salamander). USA: TENNESSEE: Union Co.: Chucks Swan Wildlife Management Area managed by the Tennessee Wildlife Resources Agency located in the White Hollow Quad (36°18'36"N, 83°57'43"W, NAD 83). 3 April 2005. W. Mark Thurman, Jon M. Davenport, and Josh R. Austin Peay State University Museum of Zoology. APSU 17705. Verified by A. Floyd Scott. Adult under tin at Heneagar Pond. New county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12, The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. [Hard copy and Internet versions, the latter of which includes links to information on Tennessee herpetology having appeared since 1996], http://www.apsu.edu/amatlas/—accessed 20 December 2005).

Voucher specimens collected under authority of Tennessee Wildlife Resources Agency; field work supported by Tennessee Wildlife Resources Agency and Austin Peay State University.

Submitted by **JOSHUA R. ENNEN** (e-mail: Joshua.Ennen@usm.edu) and **JON M. DAVENPORT**, Austin Peay State University, Clarksville, Tennessee 37040, USA; and **W. MARK THURMAN,** Tennessee Wildlife Resources Agency, 464 Industrial Blvd., Crossville, Tennessee 38555, USA.

AMBYSTOMA OPACUM (Marbled Salamander). USA: TENNESSEE: Lauderdale Co.: John Tully Wildlife Management Area managed by the Tennessee Wildlife Resources Agency located in the Golddust Quad (35.677220°N, -89.807900°W, NAD 83). 22 May 2006. Daniel Stanfield, Tennessee Wildlife Resources Agency. Austin Peay State University Museum of Zoology, APSU 18178. Verified by A. Floyd Scott. One *A. opacum* found while conducting a visual encounter survey in bottomland hardwoods near Cold Creek. Temperature at collection was 17°C. New county record that extends the range of the species in Tennessee into the southwestern corner of Lauderdale Co. (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12, The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. Hard copy and Internet versions, the latter of which includes links to information on Tennessee herpetology having appeared since 1996, http://www.apsu.edu/amatlas/; accessed 05 June 2006).

Voucher image collection made under the authority of the Tennessee Wildlife Resources Agency; field work supported by State Wildlife Grant (SWG) funding under the authority of the U.S. Fish and Wildlife Service.

Submitted by **CHRIS HUNTER**, Tennessee Wildlife Resources Agency Region I, 200 Lowell Thomas Drive, Jackson, Tennessee 38301, USA; e-mail: christopher.hunter@state.tn.us.

AMBYSTOMA OPACUM (Marbled Salamander). USA: TENNESSEE: Union Co.: Chucks Swan Wildlife Management Area managed by the Tennessee Wildlife Resources Agency located in the White Hollow Quad (36°20'50"N, 83°53'44"W, NAD 83). 3 April 2005. W. Mark Thurman, Jon M. Davenport, and Josh R. Ennen. Austin Peay State University Museum of Zoology. APSU 17705. Verified by A. Floyd Scott. Larvae in temporary pool beside White Creek, upstream of gauging station. New county record. (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12, The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. Hard copy and Internet versions, the latter of which includes links to information on Tennessee herpetology having appeared since 1996. http://www.apsu.edu/amatlas/; accessed 20 December 2005).

Voucher specimens collected under authority of Tennessee Wildlife Resources Agency; field work supported by Tennessee Wildlife Resources Agency and Austin Peay State University.

Submitted by **JON M. DAVENPORT** (e-mail: JMD1125@ecu.edu) and **JOSHUA R. ENNEN**, Austin Peay State University, Clarksville, Tennessee 37040, USA; **W. MARK THURMAN,** Tennessee Wildlife Resources Agency, 464 Industrial Blvd., Crossville, Tennessee 38555, USA.

AMBYSTOMA OPACUM (Marbled Salamander). USA: VIRGINIA: Augusta Co.: Shenandoah National Park (SNP). UTM E 692173 and N 4234579, NAD83. 20 April 2006. Milwaukee Public Museum (color voucher photo MPM P733). Larval specimen found in vernal pool in mixed hardwood forest. First record of this species within SNP (established 1939) and extends the known distribution along the eastern edge of the Shenandoah Valley NNE by 32 km (Mitchell and Reay 1999. Atlas of Amphibians and Reptiles in Virginia. Spec. Publ. No. 1, Virginia Dept. Game and Inland Fish. 122 pp.). Rockingham Co.: UTM, E 697900 and N 4242111, NAD83. 19 April 2006. MPM P734, color voucher photo. Larval specimen found in vernal pool in mixed hardwood forest. New county record and extends the known distribution along the eastern edge of the Shenandoah Valley NNE by 42 km (Mitchell and Reay 1999, *op. cit.*). Both specimens verified by Don Church, University of Virginia. These records were obtained while conducting contract research for Northeast Region of the USGS Amphibian Research and Monitoring Initiative.

Submitted by **WILLIAM BROWN**, Blue Ridge Biological, 978 Bull Yearling Road, Stanardsville, Virginia 22973, USA (e-mail: wbrown@blueridgebiological.com); and **JOHN L. BLACKBURN III**, Applied Ecology Research Group, University of Canberra, ACT 2601, Australia.

AMPHIUMA TRIDACTYLUM (Three-toed Amphiuma). USA: TENNESSEE: Fayette Co.: Wolf River Wildlife Management Area managed by the Tennessee Wildlife Resources Agency located in the SE Moscow Quad (35.029960°N, -89.266880°W, NAD 83). 11 July 2006. Daniel Stanfield and Tom Pratt of the Tennessee Wildlife Resources Agency. Austin Peay State University Museum of Zoology (APSU 18215). Verified by A. Floyd Scott. One specimen found in a turtle basket at a pond site in bottomland hardwoods. Air temperature at collection was 35°C. New county record that extends the range of the species in Tennessee into the eastern portion of Fayette Co. (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12, The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. Hard copy and Internet versions, the latter of which includes links to information on Tennessee herpetology having appeared since 1996, http://www.apsu.edu/amatlas/; accessed 22 August 2006).

Voucher image collection made under the authority of the Tennessee Wildlife Resources Agency; field work supported by State Wildlife Grant (SWG) funding under the authority of the U.S. Fish and Wildlife Service.

Submitted by **CHRIS HUNTER**, Tennessee Wildlife Resources Agency Region I,, 200 Lowell Thomas Drive, Jackson, Tennessee 38301, USA, e-mail: christopher.hunter@state.tn.us.

BOLITOGLOSSA ALBERCHI. MÉXICO: VERACRUZ: Municipality of Uxpanapa: La Horqueta (17°13'14.4"N, 94°12'53"W), 43 m elev. 7 January 2005. José Luis Aguilar-López. Verified by Luis Canseco-Márquez. Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México (MZFC 18379). First record for Uxpanapa, extending its known range in Veracruz ca. 177 km (airline) SE of the type locality near Sontecomapan (Playa Escondida) in the Los Tuxtlas area (García-Paris et al. 2002. Re. Esp. Herp. 16:43–71). The nearest published record for this species is in Chiapas, extending its range ca. 57 km (airline) NW from the El Ocote region (Muñoz Alonso et al. 1996. *In* Vásquez Sánchez and March Mifsut [eds.], Conservation y Desarrollo Sustentable en La Selva El Ocote, Chiapas, pp. 87–147. ECOSUR, San Cristobal de Las Casas [as *B. mexicana*]). The specimen was caught in a rubber tree plantation located in lowland rainforest.

Submitted by **JOSÉ LUIS AGUILAR-LÓPEZ,** Laboratorio de Herpetología, Escuela de Biología, Benemérita Universidad Autónoma de Puebla, C.P. 72570, Puebla, México (e-mail: jlal.herp@gmail.com); **CARLOS HERNÁNDEZ-JIMÉNEZ,** Museo de Zoología, Facultad de Ciencias, UNAM, C.P. 04420, México, D.F.; and **YOAZIM MELGAREJO-VÉLEZ,** Laboratorio de Herpetología, Escuela de Biología, Benemérita Universidad Autónoma de Puebla, C.P. 72570, Puebla, Mexico.

DESMOGNATHUS FUSCUS FUSCUS (Northern Dusky Salamander). USA: TENNESSEE: Union Co.: Chucks Swan Wildlife Management Area managed by the Tennessee Wildlife Resources Agency located in the White Hollow Quad (36°20'50"N, 83°53'44"W, NAD 83). 3 April 2005. W. Mark, Jon M. Davenport, and Josh R. Ennen. Austin Peay State University Museum of Zoology, APSU 17705. Verified by A. Floyd Scott. Adult under rock in spring feeding into White Creek, upstream of gauging station. New county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12, The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. Hard copy and Internet versions, the latter of which includes links to information on Tennessee herpetology having appeared since 1996, http://www.apsu.edu/amatlas/; accessed 20 December 2005).

Voucher specimens collected under authority of Tennessee Wildlife Resources Agency; field work supported by Tennessee Wildlife Resources Agency and Austin Peay State University.

Submitted by **W. MARK THURMAN,** Tennessee Wildlife Resources Agency, 464 Industrial Blvd., Crossville, Tennessee 38555, USA (e-mail: Mark.Thurman@state.tn.us); **JOSHUA R. ENNEN** and **JON M. DAVENPORT**, Austin Peay State University, Clarksville, Tennessee 37040,USA.

DESMOGNATHUS OCHROPHAEUS (Allegheny Mountain Dusky Salamander). CANADA: ONTARIO: Regional Municipality of Niagara, Niagara Gorge (north of Niagara Falls) near Queenston (43°00'N, 79°00'E). 5 June 1989. Wayne F. Weller and James Kamstra. Royal Ontario Museum (ROM 19813). Verified by Devin J. Mills and Rob Tervo based on morphological features. Two salamanders were found in a seepage area under rocks and logs. The habitat consists of a single cascade channel on a 77% slope gradient fed by groundwater seeps and flowing into the Niagara River. The salamander collected at the locality in 1989

had originally been identified as *D. fuscus* (ROM 19613) (Kamstra 1991. Can. Field-Nat. 105:561–563). Upon further investigation of morphological features it is evident that the voucher is actually *D. ochrophaeus*. In 2004, the Ontario Ministry of Natural Resources (OMNR) collected tissue samples from 19 salamanders over a period of several months. Mitochondrial DNA sequence comparisons of cytochrome b between the 19 *Desmognathus* salamanders discovered at the Queenston site and known *D. fuscus* and *D. ochrophaeus* from adjacent New York State indicate that the entire Queenston population is comprised of *D. ochrophaeus* (Markle and Green 2005. Molecular Identification of Allegheny Mountain Dusky Salamanders, *Desmognathus ochrophaeus*, in Southern Ontario. Report for Ontario Ministry of Natural Resources, Vineland, Ontario. 8 pp.). The other population of *Desmognathus* salamanders within the Niagara Gorge were confirmed to be *D. fuscus*. OMNR is currently studying the ecology of both populations. The Queenston specimens represent the first record of *D. ochrophaeus* in Ontario, and remain the only population known within the province.

Submitted by **TRICIA M. MARKLE** (e-mail: tricia.markle@mail.mcgill.ca), **DAVID M. GREEN**, Department of Biology, Redpath Museum, McGill University, 859 Sherbrooke St. West, Montreal, Quebec, H3A 2K6, Canada; **ANNE YAGI**, Ontario Ministry of Natural Resources, 4890 Victoria Ave, P.O. Box 5000, Vineland Station, Ontario, L0R 2E0, Canada; and **WAYNE F. WELLER**, Ontario Power Generation Inc., Hydro Business Environment Division, 14000 Niagara Parkway, RR #1, Niagara-on-the-Lake, Ontario, L0S 1J0, Canada.

EURYCEA CIRRIGERA (Southern Two-lined Salamander). USA: TENNESSEE: Hickman Co.: Cave Branch Cave (Tennessee Cave Survey Num. HI3) (35°40'37"N, 87°42'20"W). 22 July 2006. Matthew L. Niemiller and Brian T. Miller. Verified by Vincent A. Cobb. Adult collected and deposited in the Herpetology Collection at Middle Tennessee State University, MTSU 368C. First county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. Internet version [http://www.apsu.edu/amatlas] contains links to information regarding Tennessee distribution of amphibians recorded since 1996; accessed 1 August 2006).

Submitted by **MATTHEW L. NIEMILLER**, Department of Ecology and Evolutionary Biology, University of Tennessee, Knoxville, Tennessee 37996, USA (e-mail: mniemill@utk.edu); and **BRIAN T. MILLER**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee, 37132, USA (e-mail: bmiller@mtsu.edu).

EURYCEA CIRRIGERA (Southern Two-lined Salamander). USA: TENNESSEE: Union Co.: Chucks Swan Wildlife Management Area managed by the Tennessee Wildlife Resources Agency located in the White Hollow Quad (36°20'50"N, 83°53'44"W, NAD 83). 3 April 2005. W. Mark Thurman, Jon M. Davenport, and Josh R. Ennen. Austin Peay State University Museum of Zoology, APSU 17705. Verified by A. Floyd Scott. Adult under rock beside White Creek, upstream of gauging station. New county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12, The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. Hard copy and Internet versions, the latter of which includes links to information on Tennessee herpetology having appeared since 1996, http://www.apsu.edu/amatlas/; accessed 20 December 2005).

Voucher specimens collected under authority of Tennessee Wildlife Resources Agency; field work supported by Tennessee Wildlife Resources Agency and Austin Peay State University.

Submitted by **W. MARK THURMAN** Tennessee Wildlife Resources Agency, 464 Industrial Blvd., Crossville, Tennessee 38555, USA (e-mail: Mark.Thurman@state.tn.us); **JOSHUA R. ENNEN** and **JON M. DAVENPORT**, Austin Peay State University, Clarksville, Tennessee 37040, USA.

EURYCEA LONGICAUDA LONGICAUDA (Long-tailed Salamander). USA: VIRGINIA: Albemarle Co.: Shenandoah National Park, UTM E 696356 and N 4222471, NAD 83. 21 July 2001. Milwaukee Public Museum (color voucher photo MPM P735). Verified by Don Church, University of Virginia. Adult found under rock at the edge of Moorman's River (south fork), 8.65 km W of White Hall, Virginia. New county record and second known record east of the Blue Ridge Mountains in Virginia (Mitchell and Reay 1999. Atlas of Amphibians and Reptiles in Virginia. Spec. Publ. No. 1, Virginia Dept. Game and Inland Fish. 122 pp.). Research permit # SHEN-2001-SCI-0005.

Submitted by **WILLIAM BROWN**, Blue Ridge Biological, 978 Bull Yearling Road, Stanardsville, Virginia 22973, USA (e-mail: wbrown@blueridgebiological.com); and **JOSEPH C. MITCHELL,** Department of Biology, University of Richmond, Richmond, Virginia 23173, USA (e-mail: dr.joe.mitchell@gmail.com).

EURYCEA LUCIFUGA (Cave Salamander). USA: TENNESSEE: Hardin Co.: Entrance to Pickwick Pot (Tennessee Cave Survey Num. HR6) (35°01'37"N, 88°10'28"W). 2 July 2006. Adult collected and deposited in the Herpetology Collection at Middle Tennessee State University (MTSU 356C). First county record and most southwestern record in Tennessee (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. Internet version [http://www.apsu.edu/amatlas] contains links to information regarding Tennessee distribution of amphibians recorded since 1996; accessed 01 August 2006). Hickman Co.: Cave Branch Cave (Tennessee Cave Survey Num. HI3) (35°40'37"N, 87°42'20"W). 22 July 2006. MTSU 360C, adult. First county record. Lewis Co.: Allens Creek Cave (Tennessee Cave Survey Num. LS3) (35°26'15"N, 87°35'47"W). 22 July 2006. MTSU 359C, adult. First county record. All of the above specimens were collected by Matthew L. Niemiller and Brian T. Miller, and verified by Vincent A. Cobb.

Submitted by **MATTHEW L. NIEMILLER**, Department of Ecology and Evolutionary Biology, University of Tennessee, Knoxville, Tennessee 37996, USA (e-mail: mniemill@utk.edu); and **BRIAN T. MILLER**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee, 37132, USA (e-mail: bmiller@mtsu.edu).

EURYCEA LUCIFUGA (Cave Salamander). USA: TENNESSEE: Union Co.: Chucks Swan Wildlife Management Area managed by

the Tennessee Wildlife Resources Agency located in the White Hollow Quad (36°21'24"N, 83°55'30"W, NAD 83). 3 April 2005. W. Mark Thurman, Jon M. Davenport, and Josh R. Ennen. Austin Peay State University Museum of Zoology, APSU 17705. Verified by A. Floyd Scott. Adult in crevice of cave opening. New county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12, The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. Hard copy and Internet versions, the latter of which includes links to information on Tennessee herpetology having appeared since 1996, http://www.apsu.edu/amatlas/; accessed 20 December 2005).

Voucher specimens collected under authority of Tennessee Wildlife Resources Agency; field work supported by Tennessee Wildlife Resources Agency and Austin Peay State University.

Submitted by **JOSHUA R. ENNEN** (e-mail: Joshua.Ennen@usm.edu) and **JON M. DAVENPORT**, Austin Peay State University, Clarksville, Tennessee 37040,USA; **W. MARK THURMAN,** Tennessee Wildlife Resources Agency, 464 Industrial Blvd., Crossville, Tennessee 38555, USA.

NECTURUS MACULOSUS (Mudpuppy). USA: ILLINOIS: HENDERSON CO.: large adult salamander was live caught in a standard commercial fishing hoop-net in the Mississippi River near Dallas City, Illinois. 12 January 2004. Collected by Ron Newman, commercial fisherman. Illinois Natural History Survey (INHS 19580). Verified by Chris Phillips. Specimen is a first county record (Phillips 1999. Field Guide to Amphibians and Reptiles of Illinois).

Submitted by **JOHN K. TUCKER, JAMES T. LAMER,** and **CHAD R. DOLAN,** Illinois Natural History Survey, 8450 Montclair Ave, Brighton, Illinois 62012, USA.

NOTOPHTHALMUS PERSTRIATUS (Striped Newt). USA: FLORIDA: LEVY CO.: Goethe State Forest (29°32'0.5"N, 82°36'21.7"W). 7 March 2006. Collected by Clinton P. Smith, Libby Zimmerman, and James Blush. Verified by Kenneth L. Krysko. Florida Museum of Natural History, University of Florida (UF 146015, UF 146033). County record (Franz and Smith 1993. Distribution and Status of the Striped Newt and Florida Gopher Frog in Peninsular Florida, Report to Florida Game and Fresh Water Fish Commission, Nongame Wildlife Program, Tallahassee. 74 pp.). Three individuals (paedomorphic and terrestrial adults) were dipnetted from a prairie pond. A previous specimen was observed in Levy Co. by L. Zimmerman in February 2005 (29°21'42.6"N, 82°35'56.4"W) but no voucher specimen was collected. This closes a range gap for the species, which has been observed from adjacent counties. This new population is located ca. 1 km S of an adjacent population in Alachua Co. (voucher specimens collected 16 March 2006, UF 146012 and 24 March 2006, UF 146020).

Submitted by **CLINTON P. SMITH**, Florida Fish and Wildlife Conservation Commission, Gainesville, Florida 32601, USA (e-mail: sscpsmith@hotmail.com); and **LIBBY ZIMMERMAN**, Division of Forestry, Dunnellon, Florida 34431, USA.

NOTOPHTHALMUS VIRIDESCENS (Eastern Newt). USA: ILLINOIS: JERSEY CO.: Salamanders were live caught by minnow-fyke net in Doc's pond on the premises of Principia College, N 731407 and W 4313891, zone 15 using NAD27 CONUS map datum in UTM's. 20 April 2006, 2030 h. Five specimens collected by James T. Lamer and John K. Tucker, Illinois Natural History Survey (INHS 19963–19967). Verified by Chris Phillips, Illinois Natural History Survey. First county records (Phillips 1999. Field Guide to Amphibians and Reptiles of Illinois). Approximately 70 newts were caught in two minnow-fykes during a 24 h set. Both males and females displaying breeding characteristics were captured.

Submitted by **MARY JANE S. HOFF,** Principia College, Elsah, Illinois 62028, USA; **JAMES T. LAMER, JOHN K. TUCKER,** and **CHAD R. DOLAN,** Illinois Natural History Survey, 8450 Montclair Ave, Brighton, Illinois 62012, USA.

PLETHODON ALBAGULA (Western Slimy Salamander). USA: TEXAS: EDWARDS CO.: 6.4 air km WSW Camp Wood (29°39'00.6"N; 100°05'31.6"W). 28 January 2006. Texas Cooperative Wildlife Collections, TCWC 90870–90872. 13.6 road km N Jct FM 2631 on FM 355 (29°55'40.9"N; 100°00'48.1"W). 28 January 2006. TCWC 90873–90874. New county record and westernmost known records for the species (Dixon 2000. Amphibians and Reptiles of Texas. Second Ed. Univ. of Texas A&M Press, viii + 421 pp.). All material collected by Toby J. Hibbitts and verified by James R. Dixon.

Submitted by **TOBY J. HIBBITTS**, Texas Cooperative Wildlife Collections, Department of Wildlife and Fisheries Sciences, Texas A&M University, 2258 Tamu, College Station, Texas 77843-2258, USA; e-mail: thibbitts@tamu.edu.

PLETHODON DORSALIS (Northern Zigzag Salamander). USA. TENNESSEE: CAMPBELL CO.: Norris Dam State Park located in Norris Quad (NAD 27, UTM Zone16, Easting 759030, Northing 4014830). 11 March 2006. John E. Copeland, Daniel Douglas, and Eric Good. Austin Peay State University Museum of Zoology, APSU 18166–18167. Verified by A. Floyd Scott. One specimen caught under a log and one under a coverboard. New county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp.).

Submitted by **JOHN E. COPELAND** (e-mail: john.copeland@lmunet.edu), **DANIEL DOUGLAS**, and **ERIC GOOD**, Department of Mathematics and Natural Sciences, Lincoln Memorial University, Harrogate, Tennessee 37752, USA.

PLETHODON DORSALIS (Northern Zigzag Salamander). USA: TENNESSEE: MAURY CO.: Twilight zone of Pompie Cave (Tennessee Cave Survey Num. MU19) in Yanahli Wildlife Management Area (35°32'42"N, 86°53'25"W). 2 January 2006. Matthew L. Niemiller and Brian T. Miller. Verified by A. Floyd Scott. Color photo voucher in Austin Peay State University Herpetological Collection (APSU 18182). First county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp.).

Submitted by **MATTHEW L. NIEMILLER** and **BRIAN T. MILLER**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA (e-mail: bmiller@mtsu.edu).

PLETHODON GLUTINOSUS (Northern Slimy Salamander). USA: TENNESSEE: BEDFORD Co.: Vicinity of Warren Springs, 3.4 km NE of the town of New Herman (35°21'03"N, 86°24'34"W). 27 April 2006. Brad M. Glorioso and Matthew L. Niemiller. Verified by Brian T. Miller. Voucher specimen in Herpetology Collection at Middle Tennessee State University (MTSU 343C). First county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp.).

Submitted by **BRAD M. GLORIOSO**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee, 37132, USA (e-mail: bmg2g@mtsu.edu); and **MATTHEW L. NIEMILLER,** Department of Ecology and Evolutionary Biology, The University of Tennessee, Knoxville, Tennessee 37996, USA (e-mail: mniemill@utk.edu).

SIREN INTERMEDIA. (Lesser Siren). USA: TENNESSEE: FAYETTE Co.: Wolf River Wildlife Management Area managed by the Tennessee Wildlife Resources Agency located in the SE Moscow Quad (35.031960°N, -89.266790°W, NAD 83). 12 July 2006. Daniel Stanfield and Tom Pratt of the Tennessee Wildlife Resources Agency. Austin Peay State University Museum of Zoology (APSU 18214). Verified by A. Floyd Scott. One specimen found in a minnow trap at Mineral Slough. Air temperature at collection was 31°C. New county record that extends the range of the species in Tennessee into the eastern portion of Fayette Co. (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12, The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. [Hard copy and Internet versions, the latter of which includes links to information on Tennessee herpetology having appeared since 1996], http://www.apsu.edu/amatlas/, accessed 22 August 2006).

Voucher image collection made under the authority of the Tennessee Wildlife Resources Agency; field work supported by State Wildlife Grant (SWG) funding under the authority of the U.S. Fish and Wildlife Service.

Submitted by **CHRIS HUNTER**, Tennessee Wildlife Resources Agency Region I, 200 Lowell Thomas Drive, Jackson, Tennessee 38301, USA; e-mail: christopher.hunter@state.tn.us.

SIREN INTERMEDIA NETTINGI (Western Lesser Siren). USA: ARKANSAS: CLEVELAND Co.: Backwaters of Saline River at U.S. Hwy. 79, 56 km NE of Kingsland (Sec. 27, T9S, R11W). 28 October 2005. Henry W. Robison. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 30136). Verified by Stanley E.Trauth. New county record in southern Arkansas (Trauth et al. 2004. Amphibians and Reptiles of Arkansas, Univ. of Arkansas Press, Fayetteville).

Submitted by **HENRY W. ROBISON**, Department of Biological Sciences, Southern Arkansas University, Magnolia, Arkansas 71754-9354, USA; e-mail: hwrobison@saumag.edu.

SIREN INTERMEDIA NETTINGI (Western Lesser Siren). USA: TEXAS: MATAGORDA Co.: Specimen collected from the stomach of a female American Alligator with a SVL of 99.1 cm. The alligator was captured in Brant Lake on the Mad Island Wildlife Management Area by Marc Ealy, Kevin Kriegel, Todd Merendino, and Matt Nelson (28°41.322'N, 96°02.618'W) on 30 June 2005. The alligator was lavaged and released in Brant Lake. Diet analysis was conducted at Texas A&M University (TCWC 91579). Verified by Toby Hibbitts. New county record (Dixon 2000. Amphibians and Reptiles of Texas, Second edition, Texas A&M Univ. Press, College Station. 421 pp.). Fills in the hiatus between Brazoria and Calhoun counties.

Submitted by **KJ LODRIGUE, JR.**, Texas A&M University, Department of Wildlife & Fisheries Sciences, College Station, Texas 77843-2258, USA.

ANURA

ACRIS GRYLLUS GRYLLUS (Southern Cricket Frog). USA: NORTH CAROLINA: ANSON Co.: 4.2 km NW Pee Dee (34°57'57"N, 79°55'15"W). 16 June 2006. J. C. Beane and L. T. Pusser. Verified by Alvin L. Braswell. North Carolina State Museum of Natural Sciences (NCSM 70971). New county record. Extends range west of Pee Dee River and ca. 17 km WNW of nearest records in Richmond Co. (NCSM files). Martof et al. (1980. Amphibians and Reptiles of the Carolinas and Virginia, University of North Carolina Press, Chapel Hill, 264 pp.).

Submitted by **JEFFREY C. BEANE**, North Carolina State Museum of Natural Sciences, Research Laboratory, 4301 Reedy Creek Road, Raleigh, North Carolina 27607, USA (e-mail: jeff.beane@ncmail.net); and **L. TODD PUSSER**, P.O. Box 122, West End, North Carolina 27376 USA (e-mail: tpusser@nc.rr.com).

APLASTODISCUS (= HYLA) SIBILATUS. BRAZIL: ALAGOAS: Murici Municipality, Fazenda Bananeira (09°15'S, 35°50'W, 550 m elev.). 16 November 2005. M. G. De Lima, G. Skuk, C. A. G. Cruz, M. Cardoso da Silva. Museu de História Natural da Universidade Federal de Alagoas, Maceió, Alagoas (MUFAL 5853–5854). Verified by C. A. Gonçalves da Cruz. Previously known from the municipalities of Cairu, Ibirapitanga, Itamari, and Santa Terezinha, Bahia State, northeastern Brazil (Cruz et al. 2003. Bol. Mus. Nac., N. S. Zool., Rio de Janeiro. 503:1–13). First state record, extends known distribution ca. 588 km N from Cairu, Bahia State.

Submitted by **MARCELO G. DE LIMA** (e-mail: delima@graffiti.net), **GABRIEL SKUK** (e-mail: gabrielskuk@aol.com), Museu de História Natural da Universidade Fedral de Alagoas, 57021-090, Maceió, Alagoas, Brazil; and **MONICA C. BATRACHYLA LEPTOPUS (Gray Wood Frog). CHILE: XI REGION DE AYSEN: COYHAIQUE PROVINCE: Coyhaique National Reserve (71°30'5"W, 45°31'33"S, 762 m elev.). January 2006. H. Díaz - Páez and J. C. Ortiz. Museo de Zoología de la Universidad de Concepción (MZUC 32134, juvenile, 12.76 mm SVL; MZUC 32135–32137, adult males 27.34; 31.38; and 29.01 mm SVL). Verified by C. Ubeda. Río Ibañez (72°47'13"W, 46°11'38"S, 500 m elev.). January 2006. H. Díaz-Páez and J. C. Ortiz (MZUC 32034–32035, juveniles, 14.41 and 17.75 mm SVL, respectively; and MZUC 32036, adult male, 29.17 mm SVL). Verified by Pedro

Victoriano. Cei (1962. Batracios de Chile. Ed. Universidad de Chile, Santiago de Chile. 128 pp. + cviii) states that the distribution of this species in Chile extends from Concepcion to Puerto Bueno, Magallanes, but his map shows a discontinuous distribution from Concepcion to Aysén, and one point in Puerto Bueno in Magallanes. No voucher specimens support Cei's distribution. Formas and Brieva (2000. Gen. Mol. Biol. 23:43–48) reported the species range as from Concepción (36°47'S) to Cerro Mirador (40°08'S) with a single southern voucher specimen from the insular area of Chiloé.

The specimens mentioned herein are the first vouchers from Aysén Region. They establish a new southern range limit, and extend the known range of this species ca. 386 km SW from Chiloé island (Cei 1962, *op. cit.*).

Submitted by **HELEN DÍAZ PÁEZ** and **JUAN CARLOS ORTIZ**, Departamento de Ciencias Básicas, Campus Los Ángeles, Universidad de Concepción, Casilla 341, Los Ángeles, Chile and Departamento de Zoología, Facultad de Ciencias Naturales y Oceanográficas, Universidad de Concepción, Casilla 160-C, Concepción, Chile.

BUFO DEBILIS DEBILIS (Eastern Green Toad). USA: TEXAS: KENT CO.: FM 1081, 5 mi S jct FM261 with FM1081 (33.3839°N, 100.9132°W). 25 June 2003. J. D. McVay and M. R. J. Forstner. Verified by T. LaDuc, University of Texas, Texas Natural History Collection. TNHC 62604. New county record (Dixon 2002. Amphibians and Reptiles of Texas. 2nd Ed. Texas A&M University Press, College Station, Texas. 421 pp.). Specimen represents the first record for the county and fills a regional east/west distribution gap. Specimen was collected under TPWD permit SPR-1097-912.

Submitted by **JOHN D. McVAY**, Department of Biological Sciences, Texas Tech University, Lubbock, Texas 79409, USA (e-mail: john.mcvay@ttu.edu); and **M. R. J. FORSTNER**, Department of Biology, Texas State University at San Marcos, San Marcos, Texas 78666, USA.

BUFO AMERICANUS (American Toad). USA: ILLINOIS: SCOTT CO.: Three male toads were found calling from an ephemeral pond at the junction of Rt 100 and Sand Rd. (N 711482 and W 4389337, zone 15 using NAD27 CONUS map datum in UTM's). 6 April 2006. John K. Tucker and James T. Lamer. Deposted at the Illinois Natural History Survey in Champaign/Urbana, Illinois (INHS 20021–23). Verified by Chris Phillips. First county records (Phillips 1999. Field Guide to Amphibians and Reptiles of Illinois). Several *B. americanus* were heard calling from this site. The pond bordered an agricultural field. Substrate consisted mostly of sandy soil. In addition to the *B. americanus*, *Pseudacris streckeri*, *Rana blairi*, and *R. sphenocephala* were all heard calling from this site.

Submitted by **JAMES T. LAMER, JOHN K. TUCKER,** and **CHAD R. DOLAN,** Illinois Natural History Survey, 8450 Montclair Ave, Brighton, Illinois 62012, USA.

BUFO FOWLERI (Fowler's Toad). USA: TENNESSEE: WARREN CO.: Along the Collins River, 0.8 km ENE of the town of Shellsford (35°40'29"N, 85°42'11"W). 13 June 2006. Joshua A. Miller, Jacob H. Miller, Matthew L. Niemiller, and Brian T. Miller. Verified by Vincent A. Cobb. Voucher specimen in Herpetology Collection at Middle Tennessee State University (MTSU 152A). First county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp.).

Submitted by **JOSHUA A. MILLER, JACOB H. MILLER, MATTHEW L. NIEMILLER,** and **BRIAN T. MILLER** (e-mail: bmiller@mtsu.edu), Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA.

CARDIOGLOSSA SCHIOETZI (NCN). REPUBLIC OF CAMEROON: Mount Mbam, West Province (05°56'04"N, 10°43'36"E), ca. 1700 m asl. 28–29 July 2006; Mount Oku, Northwest Province (06°14'45"N, 10°30'23"E), ca. 1950 m asl. 16 August 2006. David C. Blackburn, Katherine S. Blackburn, L. Nono Gonwouo, Pien Huang, and Marcel Talla. Museum of Comparative Zoology (MCZ A-137911–15, 137926). Verified by José Rosado. Previously recorded from the Oshie-Obudu mountain ridge, including both the Obudu Plateau in the Cross River State of Nigeria and Acha Tugi in the Southwest Province of Cameroon (Amiet 1981. Ann. Fac. Sci. Yaoundé 28:117–131). These two localities represent, respectively, the northwestern and southeastern extents of the geographic range of this species. MCZ A-137911 (male; snout–urostyle length, SUL 23.2 mm), 137912 (male; SUL 24.2 mm), 137913 (male; SUL 24.4 mm), 137914 (male; 24.2 mm), and 137915 (male; SUL 24.4 mm) were collected between 1930 and 2100 h in primary forest near a small Fulani village on Mount Mbam. Many males of this species were calling from the leaf litter along the banks of a small, shallow stream. MCZ A-137926 (male; SUL 27.0 mm) was collected at 2000 h while calling from the leaf litter in the forested part of a farm along a steep bank of a small, shallow stream in Elak-Oku village on Mount Oku. In life, specimens were a grayish light tan with brown dorsal markings and black inguinal and lateral markings. Based on lateral and ventral coloration and pattern, as well as call structure, these specimens correspond to *C. schioetzi* and not the closely related *C. melanogaster*. The nearest previously reported locality for *C. schioetzi* is Acha Tugi, which is ca. 75 km from Mount Oku and ca. 100 km from Mount Mbam. These two new records significantly extend the range of this species, which was recently evaluated to be endangered (IUCN et al. 2006 <www.globalamphibians.org>).

Submitted by **DAVID C. BLACKBURN**, Department of Organismic and Evolutionary Biology, Harvard University, 26 Oxford Street, Museum of Comparative Zoology, Cambridge, Massachusetts 02138, USA; e-mail: dblackb@fas.harvard.edu.

CHAUNUS POMBALI (NCN). BRAZIL: ESPIRITO SANTO: Nova Lombardia (19°54.053'S, 40°29.897'W, 512 m elev.), Museu de Biologia Prof. Mello Leitão, Santa Teresa, Espírito Santo (MBML 4648); Vargem Alta (19°55.408'S, 40°38.838'W, 862 m elev.), MBML 4646 and 4649; and Pousada Paradiso (19°55.558'S, 40°35.416'S, 684 m elev.), MBML 4647. All collected 20–25 April 2006 by D. Rödder and G. J. Guarnirei and verified by M. Hoffmann. Species known from Atlantic Rain Forest and transitional areas with the Cerrado in the state of Minas Gerais, Brazil (Baldisseria et al. 2004. Arquivos do Museu Nacional, Rio de Janeiro 62:255–282). First state record, extends the distribution

200 km eastward from Parque Nacional do Caparaó, Minas Gerais, Brazil.

Submitted by **DENNIS RÖDDER**, Zoologisches Forschungsmuseum Alexander Koenig, Adenauer Allee 160, D-53113 Bonn, Germany (e-mail: d.roedder.zfmk@uni-bonn.de); **GRACIMÉRIO J. RICE**, U.S. Geological Survey, Florida Integrated Science Center, 3205 College Avenue, Ft. Lauderdale, Florida 33314, USA.

ELETHERODACTYLUS MEDEMI (NCN). COLOMBIA: CAQUETA: Municipio de Florencia, Corregimiento El Caraño, Vereda Las Brisas (01°42'17"N, 75°43'26"W), ca 1300 m elev. 27 June 2005. C. Malambo-L. and A. Marin-V. Museo de Historia Natural Universidad de la Amazonia, Florencia-Caquetá, Colombia (UAM 438–439). Verified by J. D. Lynch. This species, endemic to Colombia, was previously known only from the departments of Cundinamarca and Meta (Lynch 1994. Rev. Acad. Colomb. Cienc. 19[72]:187–193; Lynch 2006. Caldasia 28[1]:135–155) with the southernmost record in the Municipio de Cubarral (ca. 03°35'N, 73°35'W). First department record and the southernmost for the species, extends known range ca. 312 km south from the previous southern record.

Submitted by **CESAR MALAMBO-L.** (e-mail: malambocesar@latinmail.com) and **ANATOLY MARIN-V.** (e-mail: kuposqui@yahoo.com.mx), Museo de Historia Natural Universidad de la Amazonia, Florencia, Caquetá, Colombia.

ELEUTHERODACTYLUS PAULODUTRAI (NCN). BRAZIL: ALAGOAS: Quebrangulo: Reserva Ecológica de Pedra Talhada (09°19'S, 36°28'W, 370 m elev.). 22 May 2006. M. G. de Lima, B. V. S. Pimenta, C. A. G. Cruz, and G. O. Skuk. Verified by B. V. S. Pimenta. Museu de História Natural da Universidade Federal de Alagoas, Maceió, Alagoas (MUFAL 6124–6125). Previously known from the coastal region in the State of Bahia (Napoli and Brandão 2003. Herpetol. Rev. 34:161). First state record, extends distribution ca. 666 km N from Ilhéus, State of Bahia.

Submitted by **MARCELO G. DE LIMA** (e-mail: delima@graffiti.net) and **GABRIEL O. SKUK** (e-mail: gabrielskuk@aol.com), Museu de História Natural da Universidade Fedral de Alagoas, 57021-090, Maceió, Alagoas, Brazil.

GASTROPHYRNE CAROLINENSIS (Eastern Narrow-mouthed Toad). USA: ARKANSAS: Van Buren Co.: Wooded area 3.2 km N of Gravesville (Sec. 23, T9N, R13W). 28 April 2006. Henry W. Robison. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 30132). Verified by Stanley E. Trauth. New county record in northern portion of state (Trauth et al. 2004. Amphibians and Reptiles of Arkansas, Univ. of Arkansas Press, Fayetteville).

Submitted by **HENRY W. ROBISON**, Department of Biological Sciences, Southern Arkansas University, Magnolia, Arkansas 71754-9354, USA: e-mail: hwrobison@saumag.edu.

HYLA ARENICOLOR (Canyon Treefrog). USA: UTAH: Iron Co.: Kanarraville, at mouth of Spring Creek Canyon (37°21.20'N, 113°10.90'W, datum: NAD27/WGS84), 1722 m elev. 18 May 2006. J. H. Reed. Verified by J. Sites. Two specimens (pair found in amplexus) deposited in Monte L. Bean Museum (BYU 5870–5871). Three additional individuals observed in vicinity. County record. Two calling males and one adult female were found below the upstream "narrows" of the canyon at 37°30.65'N, 113°9.99'W in late April. By early June, there were tadpoles from the narrows down to about the mouth of the canyon. By 27 June the stream was intermittent at the mouth, but there were still a few tadpoles as low as 37°31.24'N, 113°11.06'W (1714 m elev.). 62 tadpoles were in an isolated pool at 37°31.24'N, 113°11.02'W (1720 m elev.). The stream became continuous above 37°31.18'N, 113°10.90'W (1727 m elev.) and there were abundant tadpoles upstream to the narrows from that point on. In early July, a flash flood washed out most of the tadpoles; those left were in the lower section from 37°31.09'N, 113°10.72'W (1738 m elev.) and lower. A calling male and an adult female were observed at 37°31.12'N, 113°10.75'W (1736 m elev.) and another calling male at 37°31.15'N, 113°10.80'W (1734 m elev.). No adults or tadpoles were ever found above the narrows, and the stream was completely dry throughout the narrows by 14 July. Extensive explorations have failed to document *H. arenicolor* in Kanarra Creek, the next drainage to the north. Spring Creek thus appears to be the northerly limit of the species along the Hurricane Cliffs faultline of southwest Utah.

Submitted by **ROBERT N. REED** (e-mail: robert_reed@usgs.gov), **MARK GROVER** (e-mail: grover@suu.edu), and **JOHN H. REED**, Department of Biology, Southern Utah University, Cedar City, Utah 84720, USA. Present address of RNR: Invasive Species Science Branch, USGS Fort Collins Science Center, 2150 Centre Ave, Bldg C, Fort Collins Colorato 80526, USA.

HYLA CINEREA (Green Treefrog). USA: ARKANSAS: Sharp Co.: near Co. Rd 64, 3.2 km E jct with Co. Rd 51, ca. 5 km SE of Hardy. 10 September 2005. Josh Engelbert and Jacob Sawyer. Verified by Chris T. McAllister. Arkansas State University Museum of Zoology Herpetology Collection (ASUMZ 29401). New county record (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univ. of Arkansas Press, Fayetteville, 421 pp.).

Submitted by **JOSH R. ENGELBERT** (e-mail: okieherper@yahoo.com), **JACOB A. SAWYER** (e-mail: jacob.sawyer@smail.astate.edu), and **STANLEY E. TRAUTH**, Department of Biological Sciences, P.O. Box 599, State University, Arkansas 72467, USA (e-mail: strauth@astate.edu).

HYLA CINEREA (Green Tree Frog). USA: ILLINOIS: JERSEY Co.: Large chorus of *H. cinerea* was heard calling from Lower Stump Lake, a backwater lake along the Illinois River (N 0711520 and W 4318112, zone 15 using NAD27 CONUS map datum in UTM's). 3 June 2006. John K. Tucker and James T. Lamer. Illinois Natural History Survey in Champaign/Urbana, Illinois (INHS 20052–58). Verified by Chris Phillips. First county records (Phillips 1999. Field Guide to Amphibians and Reptiles of Illinois). This record is the northernmost record of this species reported from Illinois. The frogs were calling from dead stalks of Rough Cocklebur (*Xanthium strumarium*). Collected on clear night with scattered lightning. Large chorus also heard calling from Upper Stump Lake only separated from Lower Stump by a narrow levee.

Submitted by **JOHN K. TUCKER, JAMES T. LAMER,** and **CHAD R. DOLAN,** Illinois Natural History Survey, 8450 Montclair Ave, Brighton, Illinois 62012, USA.

HYLA CINEREA (Green Treefrog). USA: TEXAS: FAYETTE Co.: 3.84 road km N FM 1291 on Haw Creek Road (29°58'14.6"N; 96°39'50.2"W). 2 May 2006. David Laurencio and Toby J. Hibbitts. Verified by James R. PSEUDACRIS CRUCIFER (Spring Peeper). USA: ILLINOIS: McDonough Co.: Campus of Western Illinois University, Macomb, Illinois in an ephemeral pool, ca. 50 m from a branch of the Lamoine River (N 0695928 and W 4482919, zone 15 using NAD27 CONUS map datum in UTM's). 31 March 2006. James T. Lamer and John K. Tucker. Illinois Natural History Survey in Champaign/Urbana, Illinois (INHS 19979–80). Verified by Chris Phillips, Specimens are first county records (Phillips 1999. Field Guide to Amphibians and Reptiles of Illinois). The frogs were found in amplexus at an air temperature of 10°C at 2322 h. Both *P. triseriata* and *P. crucifer* were calling from this site.

Submitted by **JAMES T. LAMER, JOHN K. TUCKER,** and **CHAD R. DOLAN,** Illinois Natural History Survey, 8450 Montclair Ave, Brighton, Illinois 62012, USA.

PSEUDACRIS CRUCIFER (Spring Peeper). USA: ILLINOIS: Pike Co.: Illinois Rt. 104, E of Meredosia, Illinois (N 0700965 and W 4410073, zone 15 using NAD27 CONUS map datum in UTM's). 30 March 2006, 2339 h, during a slow, steady rain. James T. Lamer, John K. Tucker, and Chad R. Dolan. Illinois Natural History Survey in Champaign/Urbana (INHS 19978). Verified by Chris Phillips. Specimen is a first county record (Phillips 1999. Field Guide to Amphibians and Reptiles of Illinois).

Submitted by **JAMES T. LAMER, CHAD R. DOLAN,** and **JOHN K. TUCKER,** Illinois Natural History Survey, 8450 Montclair Ave, Brighton, Illinois 62012, USA.

PHYLLODYTES LUTEOLUS. BRAZIL: RIO DE JANEIRO: Municipality of São João da Barra: Grussaí (21°44'S, 41°02'W). 8–10 November 1999. F. H. Hatano, C. F. D Rocha, and D. Vrcibradic. Museu Nacional, Rio de Janeiro (MNRJ 42416–19). Verified by José P. Pombal Jr and Mônica C. S. Cardoso. Individuals were collected in restinga habitat, inside ground bromeliads. The species appeared to be locally abundant, as numerous individuals were heard calling from inside bromeliads. *Phyllodytes luteolus* is reported to occur from the states of Paraíba to Espírito Santo (Frost 2004. Amphibian Species of the World: An Online Reference. Version 3.0, http://research.amnh.org/herpetology/amphibia/index.html). First record for the state of Rio de Janeiro and southernmost record for the species (and for the genus as well), extending its distribution ca. 125 km to the southwest of Guarapari, in the state of Espírito Santo, the previous southernmost reported locality (Bokermann 1966. An. Acad. Bras. Ciênc. 38:335–344; Peixoto and Cruz 1988. Rev. Brasil. Biol. 48:265–272).

Submitted by **DAVOR VRCIBRADIC, FÁBIO H. HATANO, CARLOS FREDERICO D. ROCHA,** and **MONIQUE VAN SLUYS**, Departamento de Ecologia, Universidade do Estado do Rio de Janeiro, 20550-011, Rio de Janeiro, RJ, Brazil.

RANA AREOLATA (Crawfish Frog). USA: ILLINOIS: Franklin Co.: DOR, Fitzgerrell Park road within Wayne Fitzgerrell State Park (N 0330390 and W 4219034, zone 16 using NAD27 CONUS map datum in UTM's). 9 March 2006. Chad R. Dolan and James T. Lamer. Illinois Natural History Survey in Champaign/Urbana, Illinois (INHS 20030). Verified by Chris Phillips. First county record (Phillips 1999. Field Guide to Amphibians and Reptiles of Illinois). This frog and several conspecifics were found dead on the road during heavy rainfall at 13.9°C air temperature at 0249 h. No *Rana areolata* were heard calling, only large choruses of Western Chorus Frogs (*Pseudacris triseriata)*.

Submitted by **CHAD R. DOLAN, JAMES T. LAMER,** and **JOHN K. TUCKER,** Illinois Natural History Survey, 8450 Montclair Ave, Brighton, Illinois 62012, USA.

RANA CAPITO AESOPUS (Florida Gopher Frog). USA: FLORIDA: Gilchrist Co.: Ft. White Mitigation Park (29°54.94'N, 82°46.88'W). November 2005. Florida Museum of Natural History (UF 145525, photo voucher). Verified by K. L. Krysko. New county record. Near mouth of active Gopher Tortoise (*Gopherus polyphemus*) burrow in sandhill habitat.

Submitted by **MELISSA P. TUCKER** and **CATHY R. HANDRICK**, Florida Fish and Wildlife Conservation Commission, 3377 East U.S. Highway 90, Lake City, Florida 32055, USA (e-mail: cathy.handrick@myfwc.com).

RANA CATESBEIANA (American Bullfrog). USA: TEXAS: Madison Co.: 9.12 road km N FM 1696 on TX 90 (30°51'24.5"N; 95°56'38.8"W). 3 May 2006. Toby J. Hibbitts and David Laurencio. Verified by James R. Dixon. Texas Cooperative Wildlife Collections, TCWC 90924. New county record (Dixon 2000. Amphibians and Reptiles of Texas. Second Ed. Univ. of Texas A&M Press, viii + 421 pp.).

Submitted by **TOBY J. HIBBITTS** and **DAVID LAURENCIO**, Texas Cooperative Wildlife Collections, Department of Wildlife and Fisheries Sciences, Texas A&M University, 2258 Tamu, College Station, Texas 77843-2258, USA (e-mail: thibbitts@tamu.edu).

RANA PALUSTRIS (Pickerel Frog). USA: TENNESSEE: Hardin Co.: Stream within Jerrolds Cave (Tennessee Cave Survey Num. HR15) (35°12'26"N, 87°59'24"W). 2 July 2006. Matthew L. Niemiller and Brian T. Miller. Verified by Vincent A. Cobb. Herpetology Collection at Middle Tennessee State University (MTSU

161A, an adult). First county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. Internet version [http://www.apsu.edu/amatlas] contains links to information regarding Tennessee distribution of amphibians recorded since 1996; accessed 01 August 2006).

MILLER**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA (e-mail: bmiller@mtsu.edu).

RANA PALUSTRIS (Pickerel Frog). USA: TENNESSEE: MAURY Co.: Twilight zone of Pompie Cave (Tennessee Cave Survey Num. MU19) in Yanahli Wildlife Management Area (35°32'42"N, 86°53'25"W). 16 June 2006. Jacob H. Miller, Joshua A. Miller, Matthew L. Niemiller, and Brian T. Miller. Verified by Vincent A. Cobb. Herpetology Collection at Middle Tennessee State University (MTSU 151A). First county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp.).

Submitted by **JACOB H. MILLER, JOSHUA A. MILLER, MATTHEW L. NIEMILLER**, and **BRIAN T. MILLER** Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA (e-mail: bmiller@mtsu.edu).

RANA SYLVATICA (Wood Frog). USA: NORTH DAKOTA: WARD Co.: 48°10'39.4"N, 101°17'45.2"W, Highway 83, Minot State University Applied Amphibian Field Ecology Lab, Drift Fence Site #2, NDSU Agricultural Research Station Farm Pond. 25 July 2006. Kenneth C. Cabarle. Verified by Chris Beachy. Minot State University, Cyril Moore Science Center Research Collections, curator Guy Hanley (CMSCRCDF-2006-002). First county record (Wheeler and Wheeler 1966. The Reptiles and Amphibians of North Dakota. University of North Dakota Press, Grand Forks, North Dakota). Adult collected from pitfall traps at amphibian drift fence site, semi-permanent pond in agricultural area. This locality represents an extension within this species range (Lannoo [ed]. 2005. Amphibian Declines: The Conservation Status of United States Species. University of California Press, Berkeley and Los Angeles; Wheeler and Wheeler 1966, *op. cit.*). Special thanks to Minot State University and North Dakota INBRE for funding this research.

Submitted by **KENNETH C. CABARLE**, Department of Biology, Minot State University, 500 University Avenue West, Minot, North Dakota 58707, USA; e-mail: kenneth.cabarle@minotstateu.edu.

RANA SYLVATICA (Wood Frog). USA: TENNESSEE: UNION Co.: Chucks Swan Wildlife Management Area managed by the Tennessee Wildlife Resources Agency located in the White Hollow Quad (36°20'50"N, 83°53'44"W, NAD 83). 3 April 2005. W. Mark Thurman, Jon M. Davenport, and Josh R. Ennen. Austin Peay State University Museum of Zoology, APSU 17705. Verified by A. Floyd Scott. Larvae caught in a temporary pond close to White Creek, upstream of gauging station. New county record. (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12, The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. Hard copy and Internet versions, the latter of which includes links to information on Tennessee herpetology having appeared since 1996, http://www.apsu.edu/amatlas/; accessed 20 December 2005).

Voucher specimens collected under authority of Tennessee Wildlife Resources Agency; field work supported by Tennessee Wildlife Resources Agency and Austin Peay State University.

Submitted by **W. MARK THURMAN,** Tennessee Wildlife Resources Agency, 464 Industrial Blvd., Crossville, Tennessee 38555, USA; **JOSHUA R. ENNEN** and **JON M. DAVENPORT**, Austin Peay State University, Clarksville, Tennessee 37040, USA (e-mail: Mark.Thurman@state.tn.us).

SCAPHIOPUS COUCHII (Couch's Spadefoot). USA: COLORADO: PROWERS Co.: 3.0 km W, 1.3 km N confluence of Cat Creek and Clay Creek (NAD 27, UTM Zone 13, Easting 705190, Northing 4195994). 24 July 2006. Joey Kellner and Amy Kellner. UCM Ancillary Collection 158 (toadlet: IMG 2341) and UCM-AC 159 (tadpoles: IMG 2336). Photos of tadpole and metamorph verified by Lauren J. Livo. First record for county and easternmost record in Colorado to date, expanding the known range 36 km to the SE of the nearest record in Bent Co. (Mackessy et al. 1999. Herpetol. Rev. 30:107).

Submitted by **JOEY KELLNER** and **AMY KELLNER**, 9500 South Estes Way, Littleton, Colorado 80127, USA.

SCINAX CUSPIDATUS (NCN). BRAZIL: ALAGOAS: Marechal Deodoro: Praia do Saco da Pedra (09°44'S, 35°49'W, sea level). 19 May 2006. M. G. De Lima, G. O. Skuk, C. A. G. Cruz, and B. V. S. Pimenta. Verified by B. V. S. Pimenta. Museu de História Natural da Universidade Federal de Alagoas, Maceió, Alagoas (MUFAL 6122–6123). The historical distribution of this species was the coastal region in the states of Espírito Santo, Rio de Janeiro, and Bahia (Silvano and Pimenta 2001. Herpetol. Rev. 32:273). This is a first state record, extending the distribution ca. 820 km N from Porto Seguro, Bahia State.

Submitted by **MARCELO G. DE LIMA** (e-mail: delima@graffiti.net) and **GABRIEL O. SKUK** (e-mail: gabrielskuk@aol.com), Museu de História Natural da Universidade Federal de Alagoas, 57021-090, Maceió, Alagoas, Brazil.

SCINAX SIMILIS (Cochran's Snouted Treefrog). BRAZIL: ESPIRITO SANTO: Santa Teresa, Pousada Paradiso (19°55.558'S, 40°35.416'W, 684 m elev.). 13 March 2006. R. L. Teixeira, D. Rödder, and G. J. Guarnirei. Museu de Biologia Prof. Mello Leitão, Santa Teresa, Espírito Santo (MBML 4482–4483). Linhares, Povoação, Fazenda Três Ilhas. 6 March 2001. A. P. Almeida (MBML 2409–2412). All verified by M. Hoffmann. Species known from Manguinhos, Bom Successo, and Amorim in the state of Rio de Janeiro (Cochran 1955. U.S. Nat. Mus. Bull. 206, 423 pp.). First state record, extending the distribution ca. 450 km N from the nearest known population in Manguinhos, Rio de Janeiro.

Submitted by **DENNIS RÖDDER**, Zoologisches Forschungsmuseum Alexander Koenig, Adenauer Allee 160, D-53113 Bonn, Germany (e-mail: d.roedder.zfmk@uni-bonn.de); **GRACIMÉRIO J. GUARNIREI**, Rua São Lourenço, 1093 Santa

Teresa, Espírito Santo, Brazil (e-mail: gracimério@yahoo.com.br); and **ROGÉRIO L. TEIXEIRA**, Museu de Biologia Prof. Mello Leitão, Av. José Ruschi, 4, Centro, 29650-000, Santa Teresa, Espírito Santo, Brazil (e-mail: rogeteix@terra.com.br).

SYRRHOPHUS CYSTIGNATHOIDES (Rio Grande Chirping Frog). USA: TEXAS: GRIMES CO.: Bedias, at jct FM 1696/2620 in vacant lot (30°46'31.8"N, 95°56'46.7"W). 7 May 2006. Toby J. Hibbitts and David Laurencio. Verified by James R. Dixon. Texas Cooperative Wildlife Collections, TCWC 90924. This invasive species has spread over much of southeast Texas. New county record (Dixon 2000. Amphibians and Reptiles of Texas. Second Ed. Univ. of Texas A&M Press, viii + 421 pp.).

Submitted by **TOBY J. HIBBITTS** (e-mail: thibbitts@tamu.edu) and **DAVID LAURENCIO**, Texas Cooperative Wildlife Collections, Department of Wildlife and Fisheries Sciences, Texas A&M University, 2258 Tamu, College Station, Texas 77843-2258, USA.

GYMNOPHIONA

CAECILIA CARIBEA (Pensilvania Caecilian). COLOMBIA: DEPARTMENT OF ANTIOQUIA: Medellín municipality, sector Belen (6°14'09.28"N, 75°36'37.51"W), 1580 m elev. February 1998. Donated by A. Restrepo. Museo de Herpetología Universidad de Antioquia, Medellín, Colombia (MHUA 3915). Verified by J. D. Lynch. Previously known only from the type locality: southern tributary stream of Samana River, Pensilvania municipality, Department of Caldas, Colombia (Lynch 2000 "1999." Rev. Acad. Colomb. Cienc. 23:317–337). *C. caribea* has been reported in Antioquia (Ruiz et al. 1996. Rev. Acad. Colomb. Cienc. 20:365–415), but an exact locality was not provided and a voucher is not available. This specimen is the first documented record for Antioquia and extends the distribution toward the northern part of Cordillera Central ca. 106 km NW from the type locality.

Submitted by **MAURICIO RIVERA-CORREA**, Grupo Herpetológico de Antioquia (GHA), Instituto de Biología, Universidad de Antioquia, Laboratorio 7-121, A.A. 1226, Medellín, Colombia; e-mail: mauriciorivera79@yahoo.com.ar.

CROCODILIA

CROCODYLUS ACUTUS (American Crocodile). USA: FLORIDA: MONROE CO.: Dry Tortugas: Dry Tortugas National Park, East Key, (24°38'57.6"N, 82°48'18.5"W). 24 May 2002. Michael S. Cherkiss, Oron L. Bass, Jr., and Frank J. Mazzotti. Photograph voucher deposited in the Everglades National Park, SFCMC Collection (DRTO 3545). Verified by John Thorbjarnarson. The historical geographic distribution of *C. acutus* in Florida included southern mainland Florida (Kushlan and Mazzotti 1989. J. Herpetol. 23:1–7) to the lower Florida Keys, with a photograph taken of a crocodile in 1935 on a beach in Key West (Neill 1971. The Last of the Ruling Reptiles: Alligators, Crocodiles, and Their Kin. 486 pp.). Recent sightings in Key West include an individual ca.1.5 m total length sighted swimming along a beach and a crocodile 2.5 m total length captured within a lagoon adjacent to a residential community (O'Hara 2005. Key West Citizen, 22 August 2005; MSC, pers. obs.). Here we report a specimen of *C. acutus* ca. 2.5 m total length observed in the Dry Tortugas National Park, marking the most isolated distribution within U.S. borders.

Submitted by **MICHAEL S. CHERKISS** (e-mail: mcherkis@ufl.edu) and **FRANK J. MAZZOTTI** (e-mail: fjma@ufl.edu), Department of Wildlife Ecology and Conservation, Fort Lauderdale Research and Education Center, University of Florida, 3205 College Avenue, Davie, Florida 33314, USA; **ORON L. BASS, JR.**, South Florida Natural Resources Center, Everglades National Park, 40001 State Road 9336, Homestead, Florida 33034, USA (e-mail: sonny_bass@nps.gov).

TESTUDINES

CHELYDRA SERPENTINA (Snapping Turtle). USA: ILLINOIS: CASS CO.: Beardstown Illinois, near 6th Street, West of US 67 (T18N, R12W, Section 16SE). 26 April 2001. John K. Tucker. Verified by Chris Phillips. Illinois Natural History Survey in Champaign/Urbana, Illinois (INHS 20031). First county record (Phillips 1999. Field Guide to Amphibians and Reptiles of Illinois). Turtle was removed from a pit along a drift fence which was constructed on sandy dredge spoil located along a backwater of the Illinois River.

Submitted by **JOHN K. TUCKER, JAMES T. LAMER,** and **CHAD R. DOLAN,** Illinois Natural History Survey, 8450 Montclair Ave, Brighton, Illinois 62012, USA.

CHRYSEMYS PICTA (Painted Turtle). USA: WASHINGON: WHITMAN CO.: Route 23, Ewan (47°07.020'N, 117°43.773'W), 515 m elev. 16 September 2006. Alex Dornburg. Verified by Kenneth V. Kardong. Color photo voucher deposited in the Washington State University Conner Museum Collection (CRCM–P–25). Adult found basking alongside roadway near drainage. Ambient temperature was 27°C. First county record. This record fills a gap in distribution data, as this species is found in neighboring Adams, Lincoln, Spokane, and Walla Walla counties (Hallock and McAllister 2005. Washington Herp Atlas. http://www.dnr.wa.gov/nhp/refdesk/herp/).

Submitted by **ALEX DORNBURG** (e-mail:dornburgalex@yahoo.com) and **ROBERT E. WEAVER,** School of Biological Sciences, Washington State University, Pullman, Washington 99164, USA (e-mail: weaverr@wsu.edu).

GRAPTEMYS OUACHITENSIS OUACHITENSIS (Ouachita Map Turtle). USA: KANSAS: KINGMAN CO.: Taken in a turtle trap in Smoots Creek just north of the South Fork of Ninnescah River (37°34.66'N, 97°49.813'W) on 15 October 2004. Shawn W. Casley. Natural History Museum, University of Kansas color slides (KU CT 11936–43). Verified by Lynnette Sievert. New county record (Taggart 2006. Kansas Herpetofaunal Atlas: an online reference. http://webcat.fhsu.edu/ksfauna/herps/index.asp?page=species). Three males were collected in a turtle trap using beef liver as bait. The turtles were photographed and are presently alive at Emporia State University in the Department of Biological Sciences.

Submitted by **SHAWN W. CASLEY** and **GREG SIEVERT,** Department of Biological Sciences, Emporia State University, Emporia, Kansas 66801, USA (e-mail: gsievert@emporia.edu).

GRAPTEMYS PSEUDOGEOGRAPHICA KOHNII (Mississippi Map Turtle). USA: TEXAS: Colorado Co.: Intact and identifiable mummified remains were found amid flood debris, 1.42 km NW of the intersection between FM 949 and Frelsburg Road on FM 949 (29.73949°N, -96.41312°W). 18 June 2006. J. Duvall and M.R.J. Forstner. Verified and accessioned by Toby Hibbits, Curator of Herpetology, Texas Cooperative Wildlife Collection (TCWC 91303). Skin samples were retained in ethanol at Texas State University (MJF 11019). First occurrence west of the Brazos River drainage system and first county record (Dixon 2000. Amphibians and Reptiles of Texas. 2nd ed. Texas A&M Univ. Press, College Station).

Submitted by **DAVID RODRIGUEZ, JOSEPHINE DUVALL,** and **MICHAEL R.J. FORSTNER,** Texas State University, San Marcos, Texas 78666, USA (e-mail: daverdz5@yahoo.com).

KINOSTERNON SUBRUBRUM HIPPOCREPIS (Mississippi Mud Turtle). USA: TEXAS: Aransas Co.: 28°14'18.5"N, 67°48'15.3"W. 01 August 2006. Curtis Jones. Verified by Lee Fitzgerald. New county record (Dixon et al. 2000. Amphibians and Reptiles of Texas. Texas A&M University Press, College Station. 195 pp. Map 45). Adult found crossing road on the Aransas National Wildlife Refuge. Because of recent rain events there was an abundance of standing water.

Submitted by **CURTIS JONES**, Aransas National Wildlife Refuge, P.O. Box 100 Austwell, Texas 77950, USA.

LEPIDOCHELYS KEMPII (Kemp's Ridley Seaturtle). USA: FLORIDA: Brevard Co.: Canaveral National Seashore, Playalinda Beach (UTM 17 533727 E, 317327 N). 13 June 2006. Florida Museum of Natural History photo voucher (UF 149613). Verified by Steve Johnson. This is the first record of a Kemp's Ridley nesting in Brevard Co. and only the fifth documented individual to nest on the east coast of Florida. This is the second Kemp's Ridley to nest in Canaveral National Seashore, and is 24.8 km S of the first record in 2003 (Fish and Wildlife Institute, Florida Fish and Wildlife Conservation Commission. 19 February 2006. Reported Nesting Activity of Kemp's Ridley, *Lepidochelys kempii* in Florida 1975–2005).

Submitted by **ROBERT H. HEGNA**, Department of Biology, Olivet Nazarene University, Bournbonnais, Illinois 60914, USA (e-mail: RHHegna@aol.com); and **MATTHEW J. WARREN**, **CANDACE J. CARTER** (e-mail: Candace_Carter@nps.gov), and **JOHN C. STINER** (e-mail: John_Stiner@nps.gov), Canaveral National Seashore, Titusville, Florida 32796, USA.

MACROCHELYS TEMMINCKII (Alligator Snapping Turtle). USA: LOUISIANA: Morehouse Parish: Bayou Bonne Idee near the end of Journey's End Road. 11 April 1997. Joe Evans. Verified by John L. Carr. Natural History Museum, University of Kansas (KU CT 11925, photo voucher, carapace only). First parish record (Dundee and Rossman 1989. The Amphibians and Reptiles of Louisiana, Louisiana St. Univ. Press, Baton Rouge. 300 pp.).

Submitted by **GEORGE M. PATTON** and **MARTHA ANN MESSINGER**, 2022 Gemini Drive, Bastrop, Louisiana 71220-3467, USA (e-mail: gpatton@bayou.com).

PELODISCUS SINENSIS (Chinese Softshell Turtle). MALAYSIA: SARAWAK: FIRST DIVISION: Sungei Sarawak: Kuching (01°35'N, 110°20'E). 2001. K. A. Jensen and I. Das. USDZ 2.4931. Verified by Kelvin K. P. Lim. First specific locality. This species has been seen for sale on the streets of downtown Kuching and on five occasions found traveling from one canal to another during rainstorms, between 2001–2006. It has been cultured for food at one licensed locality in Kuching for over 10 years. Presence of this soft-shell turtle in the rivers and canals around Kuching indicates that there is an established local population. The species is native to temperate Asia including China, Vietnam, Taiwan, and Hainan, and the Amur River of Russia (Ananjeva et al. 1998. Amphibians and Reptiles. Encyclopedia of the Nature of Russia. ABF Press, Moscow. 574 pp.), and introduced to a number of places around tropical Southeast Asia, primarily as escapees from turtle farms (Lim and Das 1999. Turtles of Borneo and Peninsular Malaysia. Natural History Publications [Borneo] Sdn. Bhd., Kota Kinabalu. xii + 151 pp.).

Submitted by **KAREN A. JENSEN** (e-mail: kitti_jensen@yahoo.com), and **INDRANEIL DAS,** Institute of Biodiversity and Environmental Conservation, Universiti Malaysia Sarawak, 94300, Kota Samarahan, Sarawak, Malaysia (e-mail: idas@ibec.unimas.my).

STERNOTHERUS CARINATUS (Razor-backed Musk Turtle). USA: TEXAS: Trinity Co.: Specimen found dead from unknown causes 500 m NE of the Trinity River under an elevated portion of State Highway 19 (30°52'24.4"N, 95°23'10.9"W). 23 September 2006. TCWC 91576. Verified by Toby Hibbitts. New county record (Dixon 2000. Amphibians and Reptiles of Texas, Second edition, Texas A&M Univ. Press, College Station. 421 pp.). Partially fills in the hiatus in east Texas between Houston and Tyler counties.

Submitted by **KJ LODRIGUE, JR.**, Texas A&M University, Department of Wildlife & Fisheries Sciences, College Station, Texas 77843-2258, USA; and **GRAHAM S. CRIGLOW**, Brazos Valley Museum of Natural History, 3232 Briarcrest Drive, Bryan, Texas 77802, USA.

STERNOTHERUS ODORATUS (Stinkpot). USA: LOUISIANA: Morehouse Parish: Irvin's Lake (32°57'N,91°56'W). February 1955. G. M. Patton. Verified by John L. Carr. Field Museum of Natural History (FMNH 246797). First parish record (Dundee and Rossman 1989. The Amphibians and Reptiles of Louisiana, Louisiana St. Univ. Press, Baton Rouge. 300 pp.).

Submitted by **GEORGE M. PATTON** and **MARTHA ANN MESSINGER**, 2022 Gemini Drive, Bastrop, Louisiana 71220-3467, USA (e-mail: gpatton@bayou.com).

TRACHEMYS SCRIPTA ELEGANS (Red-eared Slider). USA: TEXAS: Madison Co.: Specimen collected in baited trap ca. 2.7 km S of Madisonville, at the intersection of State Highway 90 and County Road 106 in Caney Creek (30°54'41.7"N, 95°54'38.4"W). 23 September 2006. TCWC 91580. Verified by Toby Hibbitts. New county record (Dixon 2000. Amphibians and Reptiles of Texas, Second edition, Texas A&M Univ. Press, College Station. 421 pp.). Fills in the hiatus between Grimes and Leon counties.

Submitted by **KJ LODRIGUE, JR.**, Texas A&M University, Department of Wildlife & Fisheries Sciences, College Station,

Texas 77843-2258, USA; and **GRAHAM S. CRIGLOW**, Brazos Valley Museum of Natural History, 3232 Briarcrest Drive, Bryan, Texas 77802, USA.

TRACHEMYS SCRIPTA ELEGANS (Red-eared Slider). USA: TEXAS: TRINITY CO.: Specimen found dead from unknown causes 400 m NE of the Trinity River under an elevated portion of State Highway 19 (30°52'20.9"N, 95°23'14.6"W). 23 September 2006. TCWC 91575. Verified by Toby Hibbitts. New county record (Dixon 2000. Amphibians and Reptiles of Texas, Second edition, Texas A&M Univ. Press, College Station. 421 pp.). Partially fills in the hiatus in east Texas between Houston and Polk counties.

Submitted by **KJ LODRIGUE, JR.**, Texas A&M University, Department of Wildlife & Fisheries Sciences, College Station, Texas 77843-2258, USA; and **GRAHAM S. CRIGLOW**, Brazos Valley Museum of Natural History, 3232 Briarcrest Drive, Bryan, Texas 77802, USA.

LACERTILIA

ANOLIS FUSCOAURATUS (Papa-vento da Amazônia; Amazon Slender Anole). BRAZIL: MINAS GERAIS: CARATINGA MUNICIPALITY: Reserva Particular do Patrimônio Natural Feliciano Miguel Abdala (19°43'53"S, 41°49'00"W). December 2000. J. Cassimiro. Museu de Zoologia da Universidade de São Paulo, São Paulo (MZUSP 95078, J. Cassimiro field number 317). Verified by M. T. Rodrigues. Previously known from Bolivia, Peru, Ecuador, Colombia, Venezuela, Guyana, Suriname, French Guiana, and Atlantic Rain forests of Brazil (Ávila-Pires 1995. Zool. Verh. Leiden 299:1–708; Peters and Donoso-Barros 1970. Catalogue of the Neotropical Squamata. Part II. Lizards and Amphisbaenians. Bull. U.S. Natl. Mus. 297:1–293). There are a small number of literature records from Brazil giving precise localities, with the southern limit being the state of Espírito Santo (Williams and Vanzolini 1980. Pap. Avul. Zool. 34[6]:99–108). This first state record extends the known distribution ca. 185 km airline W from the closest known locality in Linhares, state of Espírito Santo (Rocha 1998. Anais do VIII Seminário Regional de Ecologia, pp. 869–881).

Submitted by **JOSÉ CASSIMIRO** (e-mail: geckoides@yahoo.com.br), Departamento de Zoologia, Instituto de Biociências, Universidade de São Paulo. Caixa Postal 11.461, CEP 05422-970, São Paulo, SP, Brazil; **VINÍCIUS XAVIER** (e-mail: vinic@int.efoa.br), Universidade Federal de Alfenas, Rua Gabriel Monteiro da Silva, 714, CEP 37130-000, Alfenas, MG, Brazil; and **JAIME BERTOLUCI**, Departamento de Ciências Biológicas, Escola Superior de Agricultura "Luiz de Queiroz," Universidade de São Paulo, Av. Pádua Dias, 11, CEP 13418-900, Piracicaba, SP, Brazil (e-mail: bertoluc@esalq.usp.br).

ANOLIS HETERODERMUS (Flat Andes Anole): COLOMBIA: PUTUMAYO DEPARTMENT: VALLE DE SIBUNDOY: Municipio de Colón (01°11'N, 76°58'W), 300 m N of the cemetery, Private Natural Reserve "El Recuerdo, 2100 m elev. 21 December 2001. J. J. Mueses-Cisneros. Colección de Reptiles, Instituto de Ciencias Naturales, Universidad Nacional de Colombia, Bogotá (ICN 10594). Municipio de Colón (01°11'N, 76°58'W), 2060 m elev. 21 July 2004. T. Villarreal (ICN 10597). Municipio de Santiago (01°09'N, 77°00'W), Vereda Vijinchoy, on route to Patascoy volcano, along the Río Cristales, 2180 m elev. 11 July 2004. J. J. Mueses-Cisneros (ICN 10595-6). All verified by J. D. Lynch. This species is endemic to Colombia. Previously known from the Departments of Antioquia, Boyacá, Caldas, Cauca, Cundinamarca, Huila, and Valle, with the southernmost record in the El Tambo (02°24'N, 76°50'W), Cauca department (Lazell 1969. Breviora 325:1–23). First department records and southernmost for the species, extends known range ca. 150 km S from the southernmost previously known locality. It is highly probable that *A. heterodermus* is also present in Ecuador, because the Valle de Sibundoy is located at 01°05'–01°12'N and 76°53'–77°00'W, ca. 80 km from the boundary between Colombia and Ecuador.

Submitted by **JONH JAIRO MUESES-CISNEROS,** Instituto de Ciencias Naturales Universidad Nacional de Colombia, Apartado 7495, Bogotá, D.C., Colombia; e-mail: jjmueses@gmail.com.

ANOLIS SAGREI (Brown Anole). MÉXICO: VERACRUZ: Municipality of Minatitlán: ca. 1 km N of Minatitlán (18°01'40"N, 94°34' 01"W). 10 Nov 2004. Joan Gastón Zamora Abrego. Verified by Edmundo Pérez Ramos. Colección Herpetológica, Facultad de Ciencias, UNAM (MZFC 17763). Second record for Veracruz and extends the known range of the species ca. 88 km NW from Catemaco, San Andrés Tuxtla, Veracruz (Benítez 1997. *In* Gonzáles et al. [eds.], Historia Natural de los Tuxtlas, pp. 495–500. Univ. Nac. Autó. México, D.F.). The specimen was found on a tree in rainforest.

Submitted by **JOAN GASTÓN ZAMORA-ABREGO** (e-mail: joangastn@yahoo.com.mx), **URI OMAR GARCÍA-VÁZQUEZ**, **ADRIÁN NIETO-MONTES DE OCA,** and **LUIS CANSECO-MÁRQUEZ,** Museo de Zoología, Facultad de Ciencias, UNAM, A.P. 70-399, México D.F. 04510.

BRACHYMELES APUS (Bornean Limbless Skink). MALAYSIA: SARAWAK: MIRI DIVISION, Trail between Lepo Bunga and Pa' Rebata (03°57'43.5"N, 115°33'51.0"E). 1520 m elev. Indraneil Das. 25 September 2000. (ZRC 2.6197). Verified by Kelvin K. P. Lim. Found DOR on an abandoned logging track, at the mid-elevation of Gunung Murud. The left side of its head partially eaten by ants. The original montane forest vegetation at that elevation has been removed through clear-felling. The species was only known from Bundu Tuhan (06°01'S, 116°32'E), nr. Headquarters of Gunung Kinabalu National Park, Sabah, Malaysia (Hikida 1982. Copeia 1982[4]:840–844). The present record is the first for Sarawak, and an extension of range ca. 250 km to the southwest.

Submitted by **INDRANEIL DAS**, Institute of Biodiversity and Environmental Conservation, Universiti Malaysia Sarawak, 94300, Kota Samarahan, Sarawak, Malaysia; e-mail: idas@ibec.unimas.my.

CERCOSAURA ARGULUS (Elegant Eyed Lizard). BRAZIL: AMAZONAS: Municipality of Beruri, Reserva de Desenvolvimento Sustentável Piagaçu-Purus, Lago Ayapuá, Igarapé Ajará (04°24.988'S, 62°15.609'W, WGS 84, 11 m elev.). 29 October 2004. F. Waldez. Coleção de Anfíbios e Répteis, Instituto Nacional de Pesquisas da Amazônia, Manaus, Amazonas, Brazil (INPA-H 13845, female, 43.6 mm SVL). Igarapé Jabuti (04°26.698'S, 62°15.867'W, WGS 84, 18 m elev.). 26 May 2005.

F. Waldez. (INPA-H 13846, male, 38.2 mm SVL). Verified by V. T. Carvalho. First state record. This is an expected occurrence because the species was previously known from Bolivia, Colombia, Ecuador, French Guiana, Peru, and in the Brazilian states of Pará and Rondônia (Avila-Pires 1995. Zool. Verh. Leider. 299:1–706). This record extends the known distribution about 340 km SE (airline) from the nearest known locality: Ecological Reserve of Rio Jamari approximately 70 km SE of Porto Velho city, Rondônia, Brazil (Avila Pires, *op. cit.*).

Submitted by **FABIANO WALDEZ** (e-mail: fwaldez@inpa.gov.br) and **RICHARD C. VOGT** (e-mail: vogt@inpa.gov.br), Coleção de Anfíbios e Répteis, Instituto Nacional de Pesquisas da Amazônia, Campus II, Av André Araújo, 2936, CP 428, CEP 69.083-000, Manaus, Amazonas, Brazil.

CTENOSAURA SIMILIS (Black Spiny-tailed Iguana). USA: FLORIDA: Monroe Co.: No Name Key at N end of Spanish Channel Drive (24°42'11.7"N, 81°19'52.2"W, NAD83; elev. < 1 m). 02 May 2006. Kevin M. Enge. Verified by Gunther Köhler. Florida Museum of Natural History photo voucher (UF 149600). New county record (Krysko et al. 2003. Florida Sci. 66:74–79). Adult female observed at 1115 h on a railroad tie in a vacant lot along a limestone coastline vegetated primarily by mangroves, Australian Pine (*Casuarina equisetifolia*), and Sea Grape (*Coccoloba uvifera*). Several adults were observed in April 2006 at this site. On 02 May 2006 at 1130–1140 h, an adult was observed on private properties to the east along Bahia Shores Rd (photo voucher UF 149601) and at the N end of No Name Rd (24°42'9.2"N, 81°19'44.8"W). Phillip G. Frank (pers. comm.) knows of juveniles being collected on the island in 2005, suggesting a reproducing population.

CYRTOPODION SPINICAUDA (Spiny-tailed Thin-toed Gecko). IRAN: TEHRAN PROVINCE: Farahzaad Mountain NW of Tehran City, southern side of Central Alborz Protected Area (35°48'10"N, 51°20'23"E). 2000 m elev. 06 May 2006. Omid Mozaffari. Verified by S. C. Anderson. Iranian Society for the Study of Reptiles and Amphibians (ARIA 1000). First record for Tehran Province. An adult male was found at 1100 h under a small stone in a sloping field at the foot of mountain. The nearest reported locality for this species is from Shahrud, Semnan Province, ~ 400 km E of the locality reported here (Anderson 2000. The Lizards of Iran. Society for the Study of Amphibians and Reptiles, Ithaca, New York. 364 pp.). This is the third record for this species in Iran.

Submitted by **OMID MOZAFFARI**, No.21 Taleghani 3 Street, Ashrafi Esfehani Highway, Tehran, Iran, 14699-76599; e-mail: omozaffari@yahoo.com.

DIXONIUS VIETNAMENSIS (Vietnam Leaf-toed Gecko). VIETNAM: TAY NINH PROVINCE: Ba Den Mountain (11°21'06"–24'37"N, 106°08'41"–11'28"E), ca. 50–60 m elev. Nguyen Ngoc Sang, Hoang Duc Dat, and Nguyen Xuan Dong. Institute of Tropical Biology, Museum of Zoology (ITBMZ R05 40–47; eight adult specimens). 30 September 2005. Verified by Indraneil Das. Previously known from Nha Trang, Khanh Hoa Province (Das 2004. Raffles Bull. Zool. 52[2]:629–634). First provincial record, and ca. 320 km SW of Nha Trang.

Submited by **NGUYEN QUANG TRUONG**, **DOAN VAN KIEN**, and **NGUYEN QUOC THANG**, Department of Vertebrate Zoology, Institute of Ecology and Biological Resources, 18 Hoang Quoc Viet, Hanoi, Vietnam.

EUMECES LATICEPS (Broad-headed Skink). USA: OHIO: Butler Co.: Located as it was basking on fallen tree in the southern portion of Hueston Woods State Park (39°33'58"N, 84°45'00"W). 16 June 2006. David E. Russell and Gary W. Gerald. Miami University Herpetology Collection (MUHC 0153 photo voucher). Verified by Scott M. Moody. First county record (Wynn and Moody 2006. Misc. Cont. No. 10. Ohio Biological Survey, Columbus, Ohio. 80 pp.).

Submitted by **DAVID E. RUSSELL** and **GARY W. GERALD** Department of Zoology, Miami University, Oxford, Ohio 45056, USA; e-mail: geraldgw@muohio.edu.

EURYLEPIS TAENIOLATUS (Ribbon-sided Skink). IRAN: SEMNAN PROVINCE: 2.85 km NW of Delbar Field Station, Touran Protected Area (35°58'36.5"N, 58°02'18.8"E). 1206 m elev. 05 May 2004. Omid Mozaffari. California Academy of Sciences (CAS 228608). Verified by James F. Parham. First record for Semnan Province. An adult male was found at 1000 h under a 30 × 40 cm rock in a stone field at the foot of a small mountain. The nearest reported localities are along the Tajan River in eastern Khorasan Province, ca. 450 km NE of the locality reported here, close to the border with Turkmenistan and Afghanistan (Anderson 2000. The Lizards of Iran. Society for the Study of Amphibians and Reptiles, Ithaca, New York. 442 pp.). This is the third record for this species in Iran and the first from the Kavir Desert basin.

Submitted by **OMID MOZAFFARI**, No.21 Taleghani 3 Street, Ashrafi Esfehani Highway, Tehran, Iran, 14699-76599; e-mail: omozaffari@yahoo.com.

GYMNOPHTHALMUS UNDERWOODI (Smooth-scaled Worm Lizard). NETHERLANDS ANTILLES: SINT MAARTEN: Point Blanche, Back Bay. 22 March 2003. H. van Buel. Verified by Robert W. Henderson. MPM P732. First record for St. Maarten (Powell et al. 2005. The Reptiles and Amphibians of the Dutch Caribbean: St. Eustatius, Saba, and St. Maarten. St. Eustatius National Parks Foundation, Gallows Bay, St. Eustatius, Netherlands Antilles). This species, endemic to northern South America and possibly native on some southerly Lesser Antillean islands, was previously known to occur on Lesser Antillean islands as far north as Antigua and Barbuda and from St. Thomas, U.S. Virgin Islands (Williamson and Powell 2004. Cat. Amer. Amphib. Rept. 793:1–5). The lizard was in almond leaf litter on sand 400–500 m from shore.

Submitted by **HANS VAN BUEL**, Nieuwstraat 44, 2910 Essen, Belgium (e-mail: van.buel@belgacom.net); and **ROBERT POWELL**, Department of Biology, Avila University, Kansas City, Missouri 64145, USA (e-mail: robert.powell@avila.edu).

HEMIDACTYLUS TURCICUS (Mediterranean House Gecko). USA: ILLINOIS: WILLIAMSON CO.: Marion (37°44'N, 88°56'W). 01 October 2004. Juveniles collected in Marion city limits at a human habitation and deposited at Southern Illinois University Vertebrate Fluid Collection (SIUC R-4534). An additional juvenile (SIUC R-4533) was collected 03 March 2006 and a photo voucher (SIUC R-4535) of a juvenile collected 25 August 2003. Verified by Chris Phillips. New state record and extends the geographic range of the gecko in the Midwest (previous most northern record being Fayetteville, Arkansas; Trauth et. al. 2004. The Amphibians and Reptiles of Arkansas, University of Arkansas Press). Individuals first collected in fall 2002 which indicates a breeding population. Likely transported north along Interstate Highway 57.

OPHISAURUS ATTENUATUS ATTENUATUS (Western Slender Glass Lizard). USA: ARKANSAS: UNION CO.: Marysville (Sec. 27, T17S, R18W). 22 April 2006. Henry W. Robison. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 30137). Verified by Stanley E. Trauth. New county record in southern Arkansas (Trauth et al. 2004. Amphibians and Reptiles of Arkansas, Univ. of Arkansas Press, Fayetteville).

Submitted by **HENRY W. ROBISON,** Department of Biological Sciences, Southern Arkansas University, Magnolia, Arkansas 71754-9354, USA: e-mail: hwrobison@saumag.edu.

PHRYNOSOMA CORNUTUM (Texas Horned Lizard). USA: NEW MEXICO: SANDOVAL CO.: Town of Cochiti Lake. MSB 66805, DOR gravid female with eggs (N = 21), collected 11 June 2003; MSB 66806, DOR adult, collected 11 June 2003; MSB 66807, DOR adult, collected 12 June 2003. UTM coordinates 378707 E, 3945534 N, NAD 83, Zone 13, 1713 m. elev. Verified by J. Tom Giermakowski. New county record (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. of New Mexico Press, Albuquerque. xix + 431 pp.). Extends distribution northward from Bernalillo Co. May be an introduced population.

Submitted by **MARK L. WATSON**, New Mexico Department of Game and Fish, P.O. Box 25112, Santa Fe, New Mexico 87504, USA.

SPHAERODACTYLUS KIRBYI (NCN). ST. VINCENT AND THE GRENADINES: MUSTIQUE ISLAND, Macaroni Beach (12°53'N, 61°11'W). 30 March 2006. Mark de Silva. Verified by S. B. Hedges. MPM 33979–33980. New island record. The species was previously known only from Bequia in the St. Vincent Grenadines (Lazell 1994. Breviora 496:1–20). The lizards were found in leaf litter above the high-tide line.

Submitted by **ROBERT POWELL**, Department of Biology, Avila University, Kansas City, Missouri 64145, USA (e-mail: robert.powell@avila.edu); and **ROBERT W. HENDERSON**, Sec-

tion of Vertebrate Zoology, Milwaukee Public Museum, Milwaukee, Wisconsin 53233-1478, USA (e-mail: rh@mpm.edu).

SERPENTES

AGKISTRODON CONTORTIX PHAEOGASTER (Osage Copperhead). USA: KANSAS: Coffey Co.: Slead Native Prairie next to Jacobs Creek on the Flint Hills National Wildlife Refuge, ca. 4500 m S of Hartford, ca. 800 m N on 16th Rd (38°16'01.9"N, 95°56'42.0"W). 01 August 2004. B.W. Maher. Natural History Museum, University of Kansas color slides (KU CT 11934–35). Verified by Lynnette Sievert. New county record replacing lost county record specimen (Taggart 2006. Kansas Herpetofaunal Atlas: an Online Reference: http://webcat.fhsu.edu/ksfauna/herps/index.asp?page=species). Juvenile specimen captured along silt-fence in single-ended funnel trap. PIT tag #451E721A05 inserted; individual was photographed and released as part of an ongoing research project. A second specimen was found dead in the same trap array on 03 August 2004 and was deposited in the Sternberg Museum of Natural History (MHP 12139).

Submitted by **BRYAN W. MAHER** and **GREG SIEVERT**, Department of Biological Sciences, Emporia State University, Emporia, Kansas, 66801, USA; e-mail: gsievert@emporia.edu.

AGKISTRODON PISCIVORUS LEUCOSTOMA (Western Cottonmouth). USA: ARKANSAS: Johnson Co.: 2.4 km E Lamar (Sec. 17, T9N, R22W). 10 June 2005. Gene Leeds. Verified by S. E. Trauth. Arkansas State University Herpetological Museum (ASUMZ 30266). New county record filling a distributional hiatus in the Arkansas River Valley between Franklin and Pope counties (Trauth et al. 2004. Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville. 421 pp.). This snake has now been reported from 66 of 75 (88%) counties of the state (Trauth et al., *op. cit.*:365–368, fig. 521) and will undoubtedly be found in several others.

Submitted by **HENRY W. ROBISON**, Department of Biology, Southern Arkansas University, Magnolia, Arkansas 71754, USA (e-mail: hwrobison@saumag.edu); and **CHRIS T. McALLISTER**, Department of Physical and Life Sciences, Chadron State College, Chadron, Nebraska 69337, USA (e-mail: cmcallister@csc.edu).

AGKISTRODON PISCIVORUS LEUCOSTOMA (Western Cottonmouth). USA: TEXAS: Milam Co.: Live specimen was found 3.1 km S intersection Highway 79 and Highway 36 on Highway 36 (30.68927°N, -96.83472°W). 23 June 2006. Verified by Toby Hibbits, Texas A&M University, Texas Cooperative Wildlife Collection. TCWC 91307. New county record (Dixon 2000. Amphibians and Reptiles of Texas. Texas A&M University Press, College Station, Texas. 148 pp.). The female specimen (SVL 602 mm, TL120 mm, 380 g) was collected from under a bridge on Highway 36.

Submitted by **JULIE A. PARLOS** (e-mail: jparlos@txstate.edu), **JOHN H. DUVALL-JISHA,** and **M.R.J. FORSTNER,** Department of Biology, Texas State University, San Marcos, Texas 78666, USA.

ARIZONA ELEGANS ELEGANS (Kansas Glossy Snake). USA: KANSAS: Chase Co.: DOR at Chase County Fishing Lake, ca. 3.4 km W of Cottonwood Falls (38°22.052'N, 96°35.417'W). 07 September 2005. Michelle Gilkerson, Peter Tuttle, Victor Tuttle, and Greg Sievert. Sternberg Museum of Natural History (MHP 12140). Verified by Lynnette Sievert. New county record and extends the range east 94 km into the middle of the Flint Hills Ecoregion of Kansas (Taggart 2006. Kansas Herpetofaunal Atlas: an Online Reference. http://webcat.fhsu.edu/ksfauna/herps/index.asp?page=species). The first specimen from Chase Co. was found on 24 June 2005, ca. 1 km W of the DOR specimen and is being maintained alive at Emporia State University. This species was only known from sandy soils in Kansas and these are the first two specimens from the Flint Hills Ecoregion in either Kansas or Oklahoma.

Submitted by **GREG SIEVERT, MICHELLE GILKERSON, VICTOR TUTTLE**, and **PETER TUTTLE**, Department of Biological Sciences, Emporia State University, Emporia, Kansas, 66801, USA (e-mail: gsievert@emporia.edu).

BOIGA DRAPIEZII (White-spotted Cat Snake). THAILAND: RANONG PROVINCE: Muang District: Namtok Ngao National Park, Ngao Waterfall. Caught at night on forest floor, ca. 3 m from stream, beside Park HQ. 26 November 2004. Y. Chuaynkern, J. Sheridan, C. Chuechat, and S. Makchai. Thailand Natural History Museum (THNHM 01173). Verified by Jarujin Nabhitabhata. First provincial record. Previously known from southern Thailand in Phangnga, Songkhla, Pattani, and Narathiwat Provinces (Nabhitabhata et al. "2000" 2004. Checklist of Amphibians and Reptiles in Thailand. Office of Environmental Policy and Planning, Bangkok. 152 pp.).

Submitted by **YODCHAIY CHUAYNKERN** (e-mail: ychuaynkern@yahoo.com) and **SUNCHAI MAKCHAI,** Thailand Natural History Museum, Technopolis, Khlong 5, Khlong Luang, Pathum Thani, 12120 Thailand (e-mail: sunchaimakchai@yahoo.com).

COLUBER CONSTRICTOR FLAVIVENTRIS (Eastern Yellow-bellied Racer). USA: NEW MEXICO: Guadalupe Co., 5 km SE Vaughn off US 60, high grassland, ca. 1783 m elev. 13 September 2002. B. Hubbs. Live adult (ca. 1 m TL) under tin, released. Voucher photo in Los Angeles County Museum (LACM PC 1393). Verified by Kent Beaman. New county record. Vaughn, Jct. US 60 and US 54; 34.5934°N, 105.189°W. 09 August 2005. C. B. Grogan and W. L. Grogan. Adult found DOR. Verified by Howard Snell (MSB 72535). Specimens fill gap in the range of this species in the Pecos River basin of records 138 km to the NE in Quay Co. and 185 km SSE in Curry Co., and those in the Rio Grande basin 140 km NW in Bernalillo Co. and 150 km SW in Socorro Co. (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. University of New Mexico Press, Albuquerque, 431 pp.).

Submitted by **BRIAN HUBBS**, P.O. Box 26407, Tempe, Arizona 85285, USA (e-mail: milkmanbrian@hotmail.com); **CHARLES B. GROGAN**, Department of Music, University of Arizona, Tucson, Arizona 85721, USA (e-mail: cgrog@earthlink.net); and **WILLIAM L. GROGAN, Jr.**, Department of Biological Sciences, Salisbury University, Salisbury, Maryland 21801, USA (e-mail: wlgrogan@salisbury.edu).

CROTALUS HORRIDUS (Timber Rattlesnake). USA: NORTH CAROLINA: Rowan Co.: 8 km NE Richfield; ca. 800 m E of jct. of Reaves Island Road [SR 2148] and River Road on Alcoa Game Land (35.5298°N, 80.2085°W). 05 September 2006. Mitchell Mimier. Verified by Alvin L. Braswell. North Carolina State Museum of Natural Sciences (ALB 11931, photo voucher). New county record (Palmer and Braswell 1995. Reptiles of North Carolina. University of North Carolina Press, Chapel Hill. 263 pp.). Gravid female in various stages of decomposition. The head and tail had been removed.

Submitted by **WESLEY M. ANDERSON** (e-mail: weanderson@davidson.edu) and **MICHAEL E. DORCAS**, Department of Biology, Davidson College, North Carolina 28035-7118,USA (e-mail: midorcas@davidson.edu).

CROTALUS HORRIDUS (Timber Rattlesnake). USA: TEXAS: Washington Co.: 0.6 mi N of Texas Hwy 105 (30°17'11"N, 096°14'34"W), 293 ft elev. 15 September 2006. Bob L. Tipton and Angelita Chavez Tipton. Verified by Travis J. LaDuc. Texas Natural History Collections-Texas Memorial Museum-University of Texas (TNHC 65338). New county record. (Dixon 2000. Amphibians and Reptiles of Texas. Second Edition. Texas A&M University Press, College Station, Texas, 421 pp.). A large juvenile (422 mm) female, with one button taken DOR fresh on a paved road, hardwood forest to both sides of the road (east and west), large pasture area beginning both sides of the road about 50 m N of where the snake was collected.

Submitted by **BOB L. TIPTON** and **ANGELITA CHAVEZ TIPTON**, 15622 Ten Oaks, Tomball, Texas 77377, USA (e-mail: btipton@ghg.net); and **THOMAS A. SINCLAIR**, 12903 Cloverwood Drive, Cypress, Texas 77429-2028, USA (e-mail: tsinclair2@houston.rr.com).

CROTALUS TRISERIATUS TRISERIATUS (Mexican Dusky Rattlesnake). MÉXICO: TLAXCALA: 0.8 km S Puebla state line off Mex. Hwy. 119. 11 July 1970. P. Hubbell. Verified by George Bradley. UAZ 34495. New state record (Campbell and Lamar 2004. Venomous Reptiles of the Western Hemisphere. Cornell Univ. Press, Ithaca, New York. 870 pp.). Although Gloyd (1940. Spec. Publ. Chicago Acad. Sci. 4:1–270) and Klauber (1972. Rattlesnakes: Their Habits, Life Histories, and Influence on Mankind. 2nd ed. Univ. California Press, Berkeley, California. 1533 pp.) considered Tlaxcala to be within the geographic range of *C. triseriatus*, actual records from the state appear to be lacking.

Submitted by **ROBERT W. BRYSON, JR.**, School of Life Sciences, University of Nevada, Las Vegas, Las Vegas, Nevada 89154-4004, USA; e-mail: brysonjr@unlv.nevada.edu.

DRYOCALAMUS TRISTRIGATUS (Three-lined Tree Snake). BRUNEI DARUSSALAM: Temburong District: Kuala Belalong Field Studies Centre (04°32'N, 115°09'E). ca. 100 m elev. 06 September 2005. Jonas Maximilian Dehling. Zoological Museum of the Department of Biology, Universiti Brunei Darussalam, Bandar Seri Begawan, Brunei Darussalam (UBD G002). Verified by T. Ulmar Grafe. BELAIT DISTRICT: Sungei Liang (04°40'N, 114°28'E; ca. 5 m elev.). 15 October 1992. Indraneil Das. (UBD ID-525). Verified by Joseph K. Charles. First country records, in addition to records from Sabah and Sarawak (Stuebing 1991. Raffles Bull. Zool. 39[2]:323–362), besides Pulau Natuna in Indonesia, and Balabac and Palawan in the Philippines (Das 2006. A Photographic Guide to the Snakes and Other Reptiles of Borneo. New Holland Publishers [UK], Ltd., London/Ralph Curtis Books, Sanibel Island, Florida. 144 pp.).

Submitted by **JONAS MAXIMILIAN DEHLING**, Department of Animal Ecology and Tropical Biology, Biozentrum, University of Würzburg, Am Hubland, D-97074 Würzburg, Germany (e-mail: Jonas.M.Dehling@stud-mail.uni-wuerzburg.de); and **INDRANEIL DAS**, Institute of Biodiversity and Environmental Conservation, Universiti Malaysia Sarawak, 94300, Kota Samarahan, Sarawak, Malaysia (e-mail: idas@ibec.unimas.my).

HYDRODYNASTES GIGAS (False Water Cobra). BRAZIL: PARAÍBA: João Pessoa (07°08'S, 34°51'W). 31 March 2006. G. A. P. Filho. Coleção Herpetológica do Departamento de Sistemática e Ecologia, Universidade Federal da Paraíba, João Pessoa, Paraíba (UFPB 4316). 28 August 1987 (UFPB 2441). 1 August 1986 (UFPB 2442). 18 August 1986, M. Rodrigues. Museu de Zoologia da Universidadade de Sao Paulo, Sao Paulo (MZUSP 8985). Mamanguape: Área de Proteção Ambiental (06°47'S, 34°56'W). 2002. G. Skuk. (UFPB 3678, 4316). All verified by F. L. Franco. Previously known from northern Argentina, eastern Bolivia, Paraguay, southern, western, central, and northern Brazil (States of Rio Grande do Sul, Paraná, São Paulo, Mato Grosso do Sul, Mato Grosso, Rondônia, Amapá, and Pará), and French Guiana (Bernarde and Moura-Leite 1999. Herpetol. Rev. 30:54; Giraudo and Scrocchi 2002. Smithsonian Herpetol. Info. Serv. 132:1–53; Hoogmoed 1982. Mem. Inst. Butantan 46:219–254; Peters and Orejas-Miranda 1986. Catalogue of the Neotropical Squamata, Part I. Snakes [Revised Ed.], Smithsonian Inst. Press, Washington, D.C.). First state records, extending the distribution nearly 3000 km northwards and 1400 km eastwards from the nearest known records (São Paulo, State of São Paulo and Paragominas, State of Pará, respectively).

Submitted by **GENTIL A. PEREIRA FILHO,** Herpetologia, Departamento de Sistemática e Ecologia, Universidade Federal da Paraíba, João Pessoa, Brazil (e-mail: gentilfilho@yahoo.com); and **GIOVANNA GONDIM MONTINGELLI,** Instituto de Biociências da Universidade de São Paulo, Departamento de Zoologia, São Paulo, SP; Herpetologia, Museu de Zoologia da Universidade de São Paulo, São Paulo, SP, Brazil; e-mail: giovanna@ib.usp.br).

HYPSIGLENA TORQUATA (Nightsnake). USA: NEVADA: Washoe Co.: West side of Anaho Island, Pyramid Lake (39.957°N, 119.519°W; 1165 m elev.). 28 July 2006. C. M. Gienger and Kellie M. Kuhn. Verified by R. E. Espinoza. UNR 7721. First record of this species from Anaho Island. This species has gone undetected in previous herpetological surveys of Anaho Island (Woodbury 1966. The History and Present Status of the Biota of Anaho Island, Pyramid Lake Nevada. Unpub. M.S. Thesis. Univ. Nevada-Reno). This record is a notable addition to the snake fauna of the island as *Crotalus lutosus* and *Pituophis melanoleucus* are the only other snake species known from the island.

Submitted by **C. M. GIENGER**, **KELLIE M. KUHN**, and **C. RICHARD TRACY**, Department of Biology, MS-314, University of Nevada, Reno, Reno, Nevada 89557, USA (e-mail: gienger@biodiversity.unr.edu)

HYPSIGLENA TORQUATA (Nightsnake). USA: WASHINGTON: WHITMAN Co.: Wawawai Grade Road (46°37.728'N, 117°20.611'W), 297 m elev. 28 August 2006. Alex Dornburg. Verified by Andrew T. Storfer. Washington State University Conner Museum Collection (CRCM-P022, photo voucher). Adult found basking on roadway at 2107 h. First county record. This record extends the range of the species 48 km into southeastern Washington along the Snake River (Hallock and McAllister 2005. Washington Herp Atlas. http://www.dnr.wa.gov/nhp/refdesk/herp/).

Submitted by **ALEX DORNBURG** (e-mail: dornburgalex@yahoo.com) and **SCOTT E. VANDER PLOEG,** School of Biological Sciences, Washington State University, Pullman, Washington 99164, USA (e-mail:svanderploeg@wsu.edu).

LAMPROPELTIS CALLIGASTER (Yellow-bellied Kingsnake). USA: TENNESSEE: WARREN Co.: Along the Collins River, 1.2 km ENE of the town of Shellsford (35°40'30"N, 85°41'56"W). 13 June 2006. Matthew L. Niemiller, Joshua A. Miller, Jacob H. Miller, and Brian T. Miller. Verified by Vincent A. Cobb. Voucher specimen in Herpetology Collection at Middle Tennessee State University (MTSU 180S). Adult female captured while swimming across the Collins River. First county record and extends range ca. 47 km NE from Coffee Co. (Niemiller 2005. J. Tennessee Acad. Sci. 80:6–12) to the margin of the Eastern Highland Rim and Cumberland Plateau physiographic province (Conant and Collins 1998. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton Mifflin Co., Boston, Massachusetts).

Submitted by **MATTHEW L. NIEMILLER** (e-mail: mniemill@utk.edu), **JOSHUA A. MILLER**, **JACOB H. MILLER**, and **BRIAN T. MILLER**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee, 37132, USA (e-mail: bmiller@mtsu.edu).

LAMPROPELTIS TRIANGULUM (Milksnake). USA: COLORADO: DOLORES Co.: Coal Bed Canyon, 11 km W, 3 km N Dove Creek; NAD83, UTM Zone 12, Easting 673578, Northing 4184287. 18 August 2006. Lea Bonewell, Chris Kloster, and Jenn Logan. UCM Ancillary Collection 326. Verified by Lauren J. Livo. The specimen was collected in Coal Bed Canyon during a night survey for bats. First record for county (Hammerson 1999. Amphibians and Reptiles in Colorado, 2nd Ed. University Press of Colorado, Niwot).

Submitted by **CHRIS KLOSTER**, Colorado Division of Wildlife, Durango Service Center, 151 E. 16th St., Durango, Colorado 81301, USA.

LEPTODEIRA ANNULATA CUSSILIRIS (Duellman's Cat-eyed Snake). MÉXICO: PUEBLA: MUNICIPALITY OF TLATLAUQUITEPEC: Mazatepec: (20°01'06.5"N, 97°25'38.2"W), 537 m elev., in a coffee plantation. 23 September 2005. Israel Solano Zavaleta. Verified by Edmundo Pérez Ramos. Colección Herpetológica del Museo de Zoología Alfonso L. Herrera, UNAM (MZFC 17722). First record for Puebla and a range extension of 26 km NW of the closest known locality at Jalacingo, Veracruz (Duellman 1958. Bull. Amer. Mus. Nat. Hist. 114:1–152). An earlier specimen from San Antonio Limon, Veracruz, was erroneously reported as being from Puebla (Duellman, *op. cit.*).

Submitted by **ISRAEL SOLANO-ZAVALETA** (e-mail: crotalus.viper@gmail.com), **ANDRÉS ALBERTO MENDOZA-HERNÁNDEZ** (e-mail: andreasmeher@gmail.com), and **LUIS CANSECO-MÁRQUEZ,** Museo de Zoología, Facultad de Ciencias, UNAM, A.P. 70-399, México D.F. 04510, México (e-mail: lcm@correo.unam.mx).

LEPTOTYPHLOPS BORAPELIOTES (NCN). BRAZIL: RIO GRANDE DO NORTE: Serra Negra do Norte (6°06'S, 37°04'W). 25 April–04 May 2003. D. de Oliveira Mesquita. Verified by P. Passos. Coleção Herpetológica da Universidade de Brasília, Brasília (CHUNB 30571). This species was only known from seven localities of the Caatinga xeric formation (Vanzolini 1996. Papeis Avul. Zool., S. Paulo 39[15]:281–291). Northernmost record for the species, extends the known distribution ca. 110 km NW from Junco do Seridó, State of Paraíba, and ca. 250 km NW from Lagoa Paparí, State of Rio Grande do Norte.

Submitted by **JIANCARLO ULLOA**, Setor de Herpetologia, Departamento de Vertebrados, Museu Nacional, Universidade Federal do Rio de Janeiro, Rio de Janeiro, 20940-040, Brazil; e-mail: julloa@mn.ufrj.br.

LIOPHIS MERIDIONALIS (NCN). BRAZIL: ESPÍRITO SANTO: Município de Linhares, 19°23'S, 40°04'W. A. P. Almeida. 17 September 2001. Instituto Butantan, São Paulo (IB 70927). 18 November 2003 (IB 70929).Verified by O. A. V. Marques. A. P. Almeida. 19 October 2003. Museu Nacional, Rio de Janeiro (MNRJ 11087). Verified by R. Fernandes. Published distribution of the species includes the Brazilian Amazon, Cerrado, and Atlantic forests from the state of Rio Grande do Sul to São Paulo. The distribution also includes Argentina, Bolivia, and Paraguay (Yuki et al. 1997. Bol. Mus. Paraense Emílio Goeldi, sér. Zool. 13[1]:3–10; Dixon 1989. Smithson. Herpetol. Infor. Serv. Ser., 79; Valdujo and Nogueira 2001. Herpetol. Rev. 32:128–130). First record for the state of Espírito Santo, extends the range over 1000 km northward in the coastal Atlantic forest.

Submitted by **ANTONIO DE PADUA ALMEIDA**, Projeto TAMAR-IBAMA, Reserva Biológica de Comboios, Caixa Postal 105, CEP 29.900-970, Linhares, ES, Brazil (e-mail: tonim@tamar.org.br); **JOÃO LUIZ GASPARINI**, IPEMA - Instituto de Pesquisas da Mata Atlântica, Av. MASTICOPHIS LATERALIS LATERALIS (California Striped Racer). USA: CALIFORNIA: PLUMAS Co.: Hwy 70 at Rodger's Flat (39°57'48.1"N, 121°16'36.6"W, datum: WGS84; 2020 ft. [616 m] elev.). DOR adult male (California Academy of Sciences 233409; 649 mm SVL; 920 mm TL; 50.5 g). 03 May 2006. Verified by Jens Vindum. First known occurrence of this species in Plumas Co. (Koo and Vindum 1999. Amphibians and Reptiles of the Plumas National Forest: Historical Collections and California Academy of Sciences 1998 and 1999 Surveys. Unpubl. report on file, Department of Herpetology, California Academy of Sciences. San Francisco, California). In neighboring Butte Co., *M. lateralis lateralis* is found between 330–2160 ft elevation in brushy and

chaparral vegetation (Hayes and Cliff 1982. Herpetol. Rev. 13:85–87) and has been documented in the North Fork Feather River Canyon along the left bank near Arch Rock (39°05'08"N, 121°23'29"W; pers. obs.), Shady Rest Area (CAS 233408), Pulga Road, 0.2 mi. NE of intersection with Hwy 70 (CAS 233407), 2.6 mi. NE of Jarbo Gap on Hwy 70 (CSUC 2290), Hwy. 70 near Bardee's Bar (DOR; 39°46'49.1"N, 121°27'7.2"W; pers. obs.), and upstream of the Poe Powerhouse along the right bank (39°44'35.4"N, 121°28'24.7"W; pers. obs.) and along the left bank (39°43'54.8"N, 121°28'0.8"W; pers. obs.). We thank Jens. V. Vindum for his review of this note.

Submitted by **KEVIN D. WISEMAN** and **KARLA R. MARLOW**, Garcia and Associates (GANDA), 2601 Mission Street, Suite 600, San Francisco, California 94110, USA (e-mail: kwiseman@garciaandassociates.com).

MICRUROIDES EURYXANTHUS (Sonoran Coralsnake). USA: ARIZONA: La Paz Co.: Plomosa Mountains, Plomosa Drive (33.80340°N, 114.07933°W [NAD27]). 18 June 2004. Charles W. Linkem and Jimmy A. McGuire. MVZ 244267. Verified by Ted Papenfuss. This is the second county record of *Micruroides euryxanthus* in La Paz Co., after UAZ 45840, found in 1984 in the Chocolate Mountains, 47 km SSW of Quartzite (Palmer and Devos 1986. Herpetol. Rev. 17:27) and the third record west of the 114[th] parallel. This specimen fills a gap between two disjunct records, UAZ 45840 to the southwest and USNM 38044 (collected in 1908 in Signal, Mohave Co., Arizona) to the northeast. This record is 85 km SW of USNM 38044 and 75 km NE of UAZ 45840. The three samples mentioned, and ASU 34681 (collected in 2004 in the Cerbat Mountains, Mohave Co., Arizona; Cobb 2004. Herpetol. Rev. 35:293) suggest that the range of *M. euryxanthus* might extend to the Arizona-California border, while current sampling places the range within 24 km of the border. Distributional data are based on a search of ca. 80 institutional collections by A. T. Holycross.

Submitted by **CHARLES W. LINKEM,** University of Kansas, Natural History Museum and Biodiversity Research Center, Dyche Hall, 1345 Jayhawk Blvd, Lawrence, Kansas 66045, USA (e-mail:cwlinkem@ku.edu); and **JIMMY A. McGUIRE**, University of California Berkeley, Museum of Vertebrate Zoology, 3101 Valley Life Sciences Building, Berkeley, California 94720, USA.

NERODIA FLORIDANA (Florida Green Watersnake). USA: FLORIDA: Washington Co.: Pine Log State Forest (30°25.685'N, 85°53.053'W). 05 August 2006. John G. Himes. Verified by Paul E. Moler. Florida Museum of Natural History (FLMNH 149598–149599). New county record, near northwest periphery of distribution (Gibbons and Dorcas 2004. North American Watersnakes. A Natural History. University of Oklahoma Press, Norman). Specimens found in receding pool. At least three additional specimens were observed, but not collected, at same locality on 29 July 2006.

Submitted by **JOHN G. HIMES**, Florida Fish and Wildlife Conservation Commission, 3911 Highway 2321, Panama City, Florida 32409-1658, USA.

NERODIA RHOMBIFER (Diamond-backed Watersnake). USA: TEXAS: Lavaca Co.: Green-Dixon City Park (29°27'01"N, 97°10'57"W). 18 June 2006. Verified by Toby Hibbitts. Texas Cooperative Wildlife Collection (TCWC 90980). New county record (Dixon 2000. Amphibians and Reptiles of Texas. 2[nd] Ed. Texas A&M University Press, College Station, Texas. 421 pp.). First record for the county and completes distributional records, east to west and north to south in this region.

Submitted by **JOHN H. DUVALL-JISHA** (e-mail: JD1307@txstate.edu), **JACOB T. JACKSON,** and **M.R.J. FORSTNER**, Department of Biology, Texas State University at San Marcos, San Marcos, Texas 78666, USA (e-mail: MF@txstate.edu).

NERODIA SIPEDON (Midland Water Snake). USA: TENNESSEE: Jefferson Co.: 11 June 1951. J. Mecham. Texas Tech University (TTU 3777). Verified by T. J. LaDuc. It is absent from county record map in Gibbons and Dorcas (2004. North American Watersnakes. University of Oklahoma Press, Norman. 438 pp.); verified as new county record by A. F. Scott of Austin Peay State University (pers. comm.). Incomplete locality listed in ledger: "Tenn: Jefferson Co.: E. (25 mi E)." Specimen and entire TTU collection transferred to the TNHC (The University of Texas at Austin) in 2000.

Submitted by **JOHN D. McVAY**, Department of Biological Sciences, Texas Tech University, Lubbock, Texas 79409, USA; e-mail: john.mcvay@ttu.edu.

OPHEODRYS AESTIVUS (Rough Greensnake). USA: ARKANSAS: Sharp Co.: near County Road 64, 3.2 km E of jct with County Road 51, ca. 5 km SE of Hardy. 01 July 2006. Jacob Sawyer. Verified by Benjamin A. Wheeler. Arkansas State University Museum of Zoology Herpetology Collection (ASUMZ 30196). New county record (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univ. of Arkansas Press, Fayetteville, 421 pp.).

Submitted by **JACOB A. SAWYER** (e-mail: jacob.sawyer@smail.astate.edu) and **STANLEY E. TRAUTH**, Department of Biological Sciences, P.O. Box 599, State University, Arkansas 72467, USA (e-mail: strauth@astate.edu).

OPHEODRYS AESTIVUS (Rough Greensnake). USA: TEXAS: Austin Co.: DOR 1 km N intersection Highway 949 and Mill Creek Road on Mill Creek Road (29.87441°N, -96.31300°W). 18 June 2006. Verified by Toby Hibbits. Texas Cooperative Wildlife Collection (TCWC 90977; SVL 606 mm, TL 149 mm, 23 g). New county record (Dixon 2000. Amphibians and Reptiles of Texas. 2[nd] Ed. Texas A&M University Press, College Station, Texas. 421 pp.). This is the first recorded specimen from within Austin County, completing its distribution on the Texas coastal plains.

Submitted by **JULIE A. PARLOS** (e-mail: jparlos@txstate.edu), **JOSEPHINE DUVALL,** and **M.R.J. FORSTNER,** Department of Biology, Texas State University, San Marcos, Texas 78666, USA.

OPHEODRYS AESTIVUS (Rough Greensnake). USA: TEXAS: Williamson Co.: Six DOR specimens from five localities within the Sun City development of Georgetown, Texas. Intersection San Saba and Sun City Blvd. (09 April 2006, TNHC 65411; and 28 Sept. 2006; TNHC 65424); east end of Stetson Trail (08 May 2006, TNHC 65060), under Berry Creek Bridge at Del Webb Blvd (15 May 2006, TNHC 65061); Trail Rider, 400 m S of intersection

with Whispering Wind (24 May 2006, TNHC 65410), and intersection of Scissortail and Chickadee (09 Sept. 2006, TNHC 65423). Verified by Travis LaDuc. First county records (Dixon 2000. Amphibians and Reptiles of Texas. 2nd Edition. Texas A&M Univ. Press, College Station, 421 pp.).

Submitted by **JAMES L. CHRISTIANSEN**, Texas Natural History Collections, Texas Natural Science Center, The University of Texas at Austin, Austin, Texas 78705, USA.

PANTHEROPHIS (= ELAPHE) OBSOLETA (Western Ratsnake). USA: ARKANSAS: CLEVELAND CO.: 6.4 km NW of Rison (Sec. 31, T8S, R11W). 05 May 2006. Henry W. Robison. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 30138). Verified by Stanley E. Trauth. New county record in southern Arkansas (Trauth et al. 2004. Amphibians and Reptiles of Arkansas, Univ. of Arkansas Press, Fayetteville, 421 pp.).

Submitted by **HENRY W. ROBISON**, Department of Biological Sciences, Southern Arkansas University, Magnolia, Arkansas 71754-9354, USA; e-mail: hwrobison@saumag.edu.

PSEUDOLEPTODEIRA URIBEI (Uribe's False Cat-eyed Snake). MÉXICO: MICHOACÁN: Ejido Maquili, Aquila (18°34'46"N, 103°35'46"W), 96 m elev. 21 March 2005. Alejandro Mijangos. Verified by Aurelio Ramírez-Bautista and Javier Alvarado. Colección de Herpetología, Instituto de Recursos Naturales, Universidad Michoacana de San Nicolás de Hidalgo (INIRENA 0573). New state record that bridges the gap between previous records from coastal areas of Jalisco and Guerrero (García and Ceballos 1994. Field Guide to the Reptiles and Amphibians of the Jalisco Coast, Mexico. Fund. Ecol. Cuixmala, A.C., Inst. Biol. U.N.A.M, D.F.).

Submitted by **ALEJANDRO MIJANGOS**, **DOLORES HUACUZ**, and **ADRIAN QUIJADA-MASCAREÑAS**, Laboratorio de Herpetología, Facultad de Biología, Universidad Michoacana de San Nicolás de Hidalgo (UMSNH), Morelia 58040, Michoacán, México.

RAMPHOTYPHLOPS BRAMINUS (Braminy Blindsnake). MÉXICO: CAMPECHE: Municipality of Ciudad de Carmen (18°40'20.7"N, 91°44'42.2"W). 19 December 2005. Israel Solano Zavaleta. Verified by Edmundo Pérez Ramos. Colección Herpetológica del Museo de Zoología Alfonso L. Herrera, UNAM (MZFC 18282). First record for Yucatán, extending its range ca. 362 km W of Chetumal, Quintana Roo (Cedeño-Vázquez et al. 2003. Herpetol. Rev. 34:393–395). The specimen was found in mangrove vegetation.

Submitted by **ISRAEL SOLANO ZAVALETA, URI OMAR GARCÍA VÁZQUEZ** (e-mail: urigarcia@gmail.com), and **LUIS CANSECO MÁRQUEZ**, Museo de Zoología, Facultad de Ciencias, UNAM, A.P. 70-399, México D.F. 04510.

SIBYNOPHIS MELANOCEPHALUS (Black-headed Collared Snake). BRUNEI DARUSSALAM: TEMBURONG DISTRICT: Kuala Belalong Field Studies Centre; a tributary of Sungai Belalong, Sungai Mata Ikan (04°32'N, 115°09'E; ca. 110 m elev.). 23 August 2005. Jonas Maximilian Dehling. Zoological Museum of the Department of Biology, Universiti Brunei Darussalam, Bandar Seri Begawan, Brunei Darussalam. UBD G001. Verified by T. Ulmar Grafe. First country record, in addition to records from Sabah and Sarawak (Stuebing and Inger 1999. A Field Guide to the Snakes of Borneo. Natural History Publications [Borneo] Sdn. Bhd., Kota Kinabalu, Malaysia. viii + 254 pp.). A juvenile specimen (SVL 19.1 cm, total length 30.2 cm; 163 ventrals, 144 subcaudals). During examination, the snake dropped its tail tip which measured 22 mm and comprised 33 subcaudals.

STEGONOTUS CUCULLATUS (Slatey Grey Snake). AUSTRALIA: QUEENSLAND: TOWNSVILLE: Alligator Road, Alligator Creek (19°24'18"S, 146°56'42"E). 08 April 2005. Deborah Bower. QM J83445. Verified by Andrew Amey. Fresh DOR female (SVL 766 mm) found at 2100 h. All specimens of *S. cucullatus* located in Townsville have been associated with relatively cool, wet, montane habitats, correlated with its preference for high rainfall habitats in the relatively dry Townsville region. Previous specimens were found at Mt. Stuart (QM J81126) and Hervey's Range (QM J61798, J67364). Our specimen was found on the Mt. Elliot range. It represents the most southern record of the species and extends its range by 19 km from the previous southern limit, specimen (QM J81126) from Mt. Stuart, Townsville.

Submitted by **DEBORAH SHEENA BOWER** (e-mail: bower@aerg.canberra.edu.au), and **DANE FRANCIS TREMBATH**, Applied Ecology Institute, University of Canberra, Canberra, Australian Capital Territory, Australia 2601 (e-mail: trembath@aerg.canberra.edu.au).

STENORRHINA FREMINVILLII (Freminville's Scorpion-Eating Snake). MÉXICO: QUINTANA ROO: Municipality of Othon P. Blanco, Ejido Caobas (18°26'34"N, 89°05'02"W). 01 June 2004. Víctor H. Luja. Verified by Oscar Flores-Villela. Colección Herpetológica, Museo de Zoología, El Colegio de la Frontera Sur, Unida Chetumal, Quintana Roo (ECO-CH-H-2571). A new municipality record that bridges a gap for this species on the Mexican portion of the Yucatán Peninsula between the Chetumal area of Quintana Roo to the east (Lee 1996. The Amphibians and Reptiles from the Yucatan Peninsula. Cornell Univ. Press, Ithaca, New York. 500 pp.) and 15 miles E Escárcega, Campeche (LSUMZ 33378; not recorded by Lee 1996, *op. cit.*) to the west. The specimen was found alive during the morning on a dirt road in an area containing tropical deciduous forest.

STOLICZKIA BORNEENSIS (Stoliczka's Water Snake). MALAYSIA: SARAWAK: Miri Division, vicinity of Samling Camp at Ravenscourt (04°05'14.1"N, 115°28'42.7"E). 1351 m elev. Indraneil Das. 17 October 2003. Raffles Museum of Biodiversity Research, Zoological Reference Collection, National University of Singapore (ZRC 2.6214). Verified by Kelvin K. P. Lim. Found on root and moss-covered bank of stream, at the mid-elevation of

Gunung Murud. The original vegetation at that elevation, comprising montane forests, had been mostly removed through clear-felling. The species was only known from an unspecified site in the Gunung Kinabalu (ca. 06°01'S, 116°32'E) region, Sungei Rompon on Gunung Trus Madi (summit at 05°33'N, 116°31'E), and the Crocker Range National Park (05°24'N, 116°07'E), all within Sabah State, East Malaysia (Das 2006. Amphib. Rept. Conserv. 4[1]:3–11; Stuebing 1991. Raffles Bull. Zool. 39:323–362). The present record is the first for Sarawak, and an extension of range ca. 250 km to the southwest from the Crocker Range record.

The Forgotten Amphibians of the Republic of Maldives

FRANK GLAW
Zoologische Staatssammlung, Münchhausenstr. 21, D-81247 München, Germany
e-mail: Frank.Glaw@zsm.mwn.de

and

JOSÉ ROSADO
Department of Herpetology, Museum of Comparative Zoology Harvard University, 26 Oxford Street Cambridge, Massachusetts 02138, USA
e-mail: jrosado@oeb.harvard.edu

According to the major databases "Amphibian Species of the World" (http://research.amnh.org/herpetology/amphibia/index.php), "AmphibiaWeb" (http://amphibiaweb.org), and "Global Amphibian Assessment" (http://www.globalamphibians.org), amphibians do not occur on the Maldives (verified in January 2006). In contrast, at least one travel guide (Därr 2005), and several documents on the internet (e. g., www.bluepeacemaldives.org/biodiversity.htm and http://www.fao.org/documents/show_cdr.asp?url_file=/docrep/005/ac792e/AC792E02.htm) indicate the occurrence of one or two amphibian species, *Bufo melanostictus* and *Rana* (= *Sphaerotheca*) *breviceps* in this country. At least some of these records appear to be based on the book of P. C. Webb (1988 [1989]) which, however, was not available from libraries in Germany. A search in HerpNet (http://herpnet.org) revealed the existence of several voucher specimens of *Bufo melanostictus* in the Museum of Comparative Zoology (MCZ A-2445 and A-98720–98732 from Kaafu (= Male Atoll) and MCZ A-2446 from Addu Atoll), all collected by the Agassiz Expedition to the Maldives, most or all in 1901. An older publication (Phillips 1958) listed *Bufo melanostictus* with the following comments: "Nos. 8, 9, half-grown: Malé. Previously recorded from Malé Atoll and Addu Atoll (Laidlaw). Plentiful in Malé; mainly nocturnal; noisy croacking on wet nights. Maldivian name = Bouk." In the introduction to this paper Miss Grandison and Mr. Battersby of the British Museum (Natural History) are acknowledged for the identification of the amphibian and reptile collection. It is therefore likely that the two mentioned specimens were deposited in the BMNH. This publication and the voucher specimens leave little doubts that *Bufo melanostictus* is (or was) actually present on the Maldives. In contrast, vouchers of *Sphaerotheca breviceps* from the Maldives could not be traced and its occurrence in this country might be considered as in need of confirmation.

Call For SSAR Symposium Proposals

Symposia are important components of the Annual Meeting. They allow researchers in a given subfield to come together and present the latest research in that area; society members benefit by interacting with the symposium participants. We invite the submission of symposium proposals for SSAR at the 2008 Annual Joint Meetings of Ichthyologists and Herpetologists (JMIH) in Montreal, Canada. The following guidelines have been agreed to by SSAR, HL, and ASIH.

Proposal Submission.—Proposals (3-page maximum) for consideration by SSAR should contain the following:

- ▶ Symposium Title (or Topic).
- ▶ Name of the Symposium Organizer (phone number and e-mail address) and Symposium Co-organizers.
- ▶ Information on topic and background.
- ▶ What benefit is the topic to the Society?
- ▶ List of potential speakers and topics.
- ▶ Length of symposium (1/2 day or 1 day).
- ▶ Sources of funding other than SSAR.
- ▶ SSAR funding requested, with a short budget (maximum per request = $1,500).

PROPOSALS DUE TO SSAR COORDINATOR **by 1 February 2007**.

Proposals should be submitted to the Coordinator: Dr. Richard D. Durtsche, Department of Biological Sciences, Science Center 148, Nunn Dr., Northern Kentucky University, Highland Heights, Kentucky 41099, USA; or electronically to: durtsche@nku.edu (as PDF, Word, or RTF documents).

SSAR Review Process:

- ▶ Proposals received by the SSAR symposium coordinator will be sent for external review, and comments forwarded to the SSAR Board by mid-February.
- ▶ Recommendations from the SSAR Board (proposals ranked on merit) will be sent to the JMIH Meeting Planning Committee (MPLC) by March 1.
- ▶ The top-rated proposal from each of the four primary societies will be automatically accepted. The remaining four slots will be filled according to the rank order of merit.
- ▶ Final decisions will be made and symposium organizers will be informed of the decision by the Chair of the MPLC by 31 March one year in advance of the JMIH.

BOOK REVIEWS

Herpetological Review, 2006, 37(4), 503–504.

Amphibians of East Africa, by Alan Channing and Kim M. Howell. 2005. Cornell University Press, Sage House, 512 East State Street, Ithaca, New York 14850, USA (www.cornellpress.cornell.edu). xi + 418 pp., 24 pls. Hardcover. US $ 45.00. ISBN 0-8014-4374-1.

DAVID C. BLACKBURN
Department of Herpetology, Museum of Comparative Zoology
Harvard University, Cambridge, Massachusetts 02138, USA
e-mail: dblackb@fas.harvard.edu

The amphibians of eastern Africa can be divided into two distinct faunae. Firstly, there are widespread species that are also found in central and southern Africa. Secondly, and perhaps most interestingly, there are many species endemic to the mountains and coastal forests, both of which are recognized as hotspots of global biodiversity (Brooks et al. 2002). In terms of African amphibians, East Africa contains two 'hotpots' of diversity: the Eastern Arc Mountains of Tanzania and Kenya and the Albertine Rift mountains of Uganda, Rwanda, Burundi, and eastern Democratic Republic of Congo (Stuart et al. 2004). While herpetologists have been working in eastern Africa for more than a century, there has never been a comprehensive field guide for amphibians that is comparable to the many available for southern Africa (e.g., Rose 1962; Stewart 1967; Passmore and Carruthers 1979; Channing 2001). To date, the most thorough insight into the amphibian fauna of Kenya and Tanzania is found in the many publications of Arthur Loveridge that detail his field expeditions in eastern Africa. Over the past two decades there has been extensive survey work in both Uganda and Tanzania, which has resulted in both range extensions and the description of new species. In their book, *Amphibians of East Africa*, Alan Channing and Kim Howell provide an up-to-date summary of and an excellent introduction to the amphibian diversity found in Kenya, Tanzania, and Uganda. This book is a good complement to Channing's (2001) *Amphibians of Central and Southern Africa* and it will surely become a mainstay in the library of anyone interested in African herpetology.

The book begins with a brief history of research on East African amphibians as well as short chapters on the topography and habitats found in East Africa and threats to and conservation status of amphibian species. The historical account of East African amphibian research provides the unfamiliar reader with an excellent quick introduction. Amateur and professional herpetologists may also appreciate several books by Arthur Loveridge that are popular accounts of his field research: *Many Happy Days I've Squandered* (1944), *Tomorrow's a Holiday* (1947), and *I Drank the Zambezi* (1953). These first few chapters are welcome expansions of similar sections that comprise the Introduction to Channing's (2001) earlier book. While Channing and Howell indicate that at least one of the provided maps is 'simplified,' the information on the maps of topography, rainfall, and vegetation (Figs. 2–5) could have been expanded considerably. For instance, the topographic map provides the location of only four mountains; readers unfamiliar with the many mountains of the Eastern Arc may be confused and will need to rely on a more detailed map. This section would also be improved if literature references were included for the details provided on the distribution and description of the habitats found in eastern Africa. The chapter detailing the threats to and conservation status of East African amphibians provides sufficient detail for a general introduction and is based on the recent Global Amphibian Assessment (Stuart et al. 2004). However, as it is not incorporated into the individual species accounts, this information may be overlooked by some readers.

The bulk of the book consists of species accounts and keys to both families and genera. These comprehensive keys are the first of their kind for amphibians of these three African countries and their publication will be very useful, especially to amateur herpetologists. The keys for each family are followed by keys for each genus as well as species accounts, which are organized alphabetically. Most keys are quite adequate and some, such as those for *Phrynobatrachus* and *Ptychadena*, are very useful. Some herpetologists may be disappointed by the key for the genus *Probreviceps*, which is based largely on geography, and the lack of a key for *Hyperolius*. However, as both genera are taxonomically quite difficult, the authors cannot be faulted. In general, the keys require the specimen to be in hand in order to be identified. Every species account is accompanied by a point locality map that is an outline of Kenya, Tanzania, and Uganda. The family and species accounts are strengthened by many interesting natural history notes. References for these observations are usually provided in the bibliography but are not cited in the text. All photographs are printed in color in a series of plates in the middle of the book. In general, I found the images to be of lower quality than those found in Channing's (2001) previous book. Following the species accounts, there is a chapter on tadpoles and a short chapter written in Kiswahili on East African amphibian diversity and classification. A concluding bibliography focuses on East African amphibians, but includes references dealing with amphibians from other countries as well (e.g., Somalia, Democratic Republic of Congo, Angola, Rwanda, and Cameroon). Finally, there is a systematic index with page number references for every species account.

This book provides any interested naturalist with a good introduction to the amphibians of Kenya, Tanzania, and Uganda. The book is generally well-organized and provides the most thorough summary of East African amphibian diversity to date. I know of no omissions of amphibian taxa that occur in these three countries. Even though the information for a given species, including conservation status, species accounts, color photographs, and tadpole descriptions, is distributed throughout the book, the book should still function as a handy guide in the field. Through a combination of the text and the distributional maps, one should be able to predict the amphibian fauna that will be encountered at a

given locality. As noted in the introduction, the distributional maps are based on the literature, museum collections, and field notes of the authors and their colleagues; unfortunately, specific sources for the distribution data for are not provided in the species accounts. It is unclear why the authors did not include the amphibian faunae of Rwanda and Burundi as these are commonly included within East Africa (e.g., Spawls et al. 2002; Stevenson and Fanshawe 2003).

I found several misstatements in the text, but most are inconsequential. In the section on classification, the families of amphibians in East Africa are briefly described and the genera occurring there are listed. However, in several cases it is not noted that the genera mentioned are only those that occur in East Africa. Thus, it is incorrect that the Scolecomorphidae consists of one genus (p. 36; corrected on p. 349), that the Bufonidae consists of six genera, and that the Hyperoliidae consists of five genera (p. 37). Likewise, for both *Nectophrynoides* and *Leptopelis*, the number of species stated to occur in East Africa is inconsistent with the number of species accounts provided. In general, the authors follow the conventional family-level taxonomy of Frost (2004), but amphibian systematists may be frustrated by the lack of explanation for placing the anuran ranoid family Petropedetidae (e.g., *Arthroleptides*, *Cacosternum*, and *Phrynobatrachus*) within the Ranidae.

Other errors or inconsistencies will be confusing or misleading for the amateur and professional alike. For example, the authors state that nothing is known of the breeding biology of *Arthroleptis adolfifriederici* and *Afrixalus uluguruensis*, yet there are color plates that depict clutches of eggs assigned to both species. In addition, the treatment of *Parhoplophryne usambarica* is odd as, to my knowledge, there is only a single specimen known. Channing and Howell state that *P. usambarica* "females reach a length of 23 mm" and that this "species inhabits leaf litter" (p. 227) but the holotype is an immature female that was collected in a wild banana plant (Barbour and Loveridge 1928). There are several inconsistencies in spelling. For instance, two different spellings are used for the Taita Hills in Kenya (e.g., Taita, p. 93; Teita, p. 19). The authors use the conventional spelling for the Shambala people (e.g., p. 4, 177) but also employ two other variant spellings (Sambaa, p. 4; Shambara, p. 69; Gordon 2005). Similarly, other languages are referred to using multiple terms: Ganda and Luganda; Makonde and Kimakonde; Nyakusa and Kinyakusa; Yao and Kiyao.

Inclusion of names for different genera and species in languages indigeneous to Kenya, Tanzania, and Uganda makes this book particularly useful to field biologists. Remarkably, Channing and Howell have included names from more than 40 languages, although several of these are not typically spoken in East Africa (e.g., Chewa (Malawi), Kalanga (Zimbabwe), or Lwena (Zambia and Angola)). There are a few inconsistencies, and the local names given to particular species are probably best considered as tentative. For instance, *jula* is cited as both the Shambala word for "all frogs" as well as the specific name of *Bufo brauni*. Likewise, *isodo* is cited as both the Gisu name for "all frogs" and the specific name for *Afrana angolensis*. I do not think that the authors intended to provide a definitive list and in many cases certain words apply to multiple taxa (such as in many of the Ugandan languages where the same words are used for *Afrana*, *Ptychadena*, and *Phrynobatrachus* species).

One point that is implicit throughout the book is that there is still little known about the biology of most East African amphibians. Future research should focus on aspects of biology including diet, breeding biology, and tadpole ecology. Without this information, it is difficult to make informed conservation management choices regarding preservation of particular habitats or captive breeding programs. Undoubtedly, Channing and Howell's book will be very useful to field biologists as it provides a thorough introduction to the amphibians of East Africa. Most importantly, this work highlights that there is still much to be done even in biodiversity hotspots in which the fauna is relatively well documented.

Pakistan's location and rather diverse topographical features (widely albeit mistakenly considered by some as entirely arid) have much to do with its rich herpetofauna. The country forms the easternmost frontier of a number of Palearctic taxa, stretching from northern Africa and Europe, as well as the westernmost edge of Oriental ones, extending from eastern Asia. This country, thus, forms the melting pot of two distinct faunas, and includes a number of autochthonous elements, particularly amongst its high altitude saurofauna and its deserticolous snakes. Much of Pakistan's biota is under threat, from development and overexploitation, as well as from lack of knowledge (Anon., 2000).

Islam took early root here, and some of the greatest human migrations took place around the middle of last century, when millions of Muslims from the newly independent (in 1947) India crossed over to Pakistan, just as millions of Hindus and other non-Muslims from Pakistan fled their homes in Pakistan in favor of India. This was accompanied by free bloodletting on both sides, abetted, if not aided by local governments, and was to result in mutual hostility and suspicion (and three wars) for nearly five decades. Only very recently have overtures of peace been made and both nations seem to have forsaken violence in favor of nation-building. Under such historic circumstances, research or explorations of a shared fauna had taken a back seat, and much of the information on the biota of the borders of these volatile nuclear-armed neighbors stem from expeditions and other boundary missions conducted during colonial times.

The importance of science for the welfare of her citizens was not lost to Pakistan's new ruling class. In an inaugural address to the All-Pakistan Science Conference in 1949, the then Governor-General H. E. Khawaja Nazimuddin noted "If we are to build our State on progressive lines and bring about a radical change in the living conditions of our people, we shall have to make them scientific minded and harness the resources of science for the solution of the problems facing the country" (Anon. 1950). Over half a century later, this truth is being realized.

This work is by Pakistan's foremost student of herpetology, Professor Muhammad Sharif Khan, formerly of the Herp Laboratory, Rabwah, Pakistan. For the last decade, Khan has been living in the U.S., and has published widely on all herpetofaunal groups, both in his native Pakistan and, more recently, in books published in the West. The volume under review can be considered a synthesis of a life's work on an interesting fauna, and as such, has no peer.

After a brief dedication (to Dr. and Mrs. Habib Ullah Khan, Ahsanul Islam, Robert Mertens and Sherman A. Minton, after some of whom the author has already named snake species) and a Foreword (by Kraig Adler), are the Preface (which describes the organization of the book), Acknowledgments and an extended Introduction (including a useful political map of Pakistan). Chapter 1 shows 24 species and subspecies of amphibians and 203 of reptiles in the national checklist. The total taxon count is hard to arrive at from this chapter. Adler (p. ix), in his Foreword, counted 24 species (but this includes subspecies recognized for Pakistan by Khan). In the species list, there are inconsistencies in the format adopted, with the inclusion of subspecies name of some (e.g., *Bufo melanostictus* and *Bufo viridis*), but not all (e.g., *Lissemys punctata andersoni* and *Eryx tataricus*) polytypic taxa where the type subspecies do not occur in Pakistan. Included as valid is Khan's (1997) *Bufo siacheninsis*, treated as synonymous with *B. latastii* Boulenger, 1882, by Stöck et al. (2001). Two additional taxa may be added to this fauna. Das et al. (1998) revived from obscurity the lygosomine skink, *Asymblepharus tragbulensis*, collected from the western Himalayas by the Pamir Boundary Commission towards the end of the nineteenth century, and Macey et al. (2006) included *Bufoniceps laungwalansis* from Pakistani territory, based on the largely unpublished work of the late Walter Auffenberg (T. Papenfuss, pers. comm.).

As to the main body of the book itself, I am pleased to see maps printed in two colors, each species distribution represented with a dot map. It would perhaps been useful to have a gazetteer of localities, but this would increase the number of pages (and the cost). Some of the Pakistani endemics have been illustrated from life for the first time in color. Certainly, it was the first time I saw color images of *Bufo melanostictus hazarensis* (page 44), *Bufo viridis zugmayeri* (page 52), *Paa barmoachensis* (page 62), *Paa hazarensis* (page 64), *Paa sternosignata* (page 65), *Cyrtopodion kohsulaimanai* (page 129), *Siwaligekko dattanensis* (page 146), *Siwaligekko mintoni* (page 147), and *Enhydris pakistanica* (page 196). Surprisingly, *Chamaeleo zeylanica* is not illustrated. While this species may be rare in Pakistan, images of this species are readily available from populations in India and Sri Lanka. A handful of photographs are of preserved specimens– still useful in my opinion– and better than a 100-word description.

On the matter of nomenclature used in this work, it is somewhat of a mixed bag. Traditionally, workers in the Subcontinent have clung to Smith's three volumes on reptiles in the *Fauna of British India* series, published 1931, 1935, and 1943, overlaying it with new revisions for particular groups. The amphibian taxonomy follows that proposed primarily on phenetic criteria by Dubois (1986; 1992). Some of the relevant papers may not have been available to the author, and indeed, the amphibians will see a substantial change at the generic level if *The Amphibian Tree of Life* nomenclature of Frost et al. (2006) is adopted. Nomenclature for turtles is somewhat dated in that it does not follow Spinks et al. (2004),

in which both Pakistani species of *Kachuga* are assigned to *Pangshura*, and in the allocation of this and related genera to the Emydidae rather than the Geoemydidae. Lizard nomenclature is more current, in that the following genera are used: *Brachysaura*, *Laudakia*, *Trapelus* (following Moody's 1980 upublished thesis); *Mesalina* (from Arnold 1986); *Eutropis* (following Mausfeld et al. 2002); *Novoeumeces* (fide Griffith et al. 2000). On the other hand, Khan adopts his recent (Khan 2003a, 2005b) higher classification of geckos (including the genera *Altigekko*, *Indogekko*, and *Siwaligekko*) that most modern workers would hesitate to accept because of its phenetic approach. This does not, of course, imply that the work of the author on the group is trifling, and Khan's (2003b) review of *Cyrtopodion* presents much new information relevant to both systematics and natural history of these lizards. Nomenclature adopted for snakes is again largely from Smith (1943), with updates based on the work of more recent authors, such as *Amphiesma* (fide Malnate 1960); *Hemorrhois* (adopting the nomenclature of Inger and Clark 1943; Schätti and Utiger 2001); *Platyceps* (fide Schätti and Utiger 2001); *Daboia* (fide Hermann et al. 1992); and *Gloydius* (fide Hoge and Romano-Hoge 1981). Dated or otherwise incorrect nomina used include: *Agrionemys* for *Testudo* (fide Crumly 1982; Sqalli-Houssaini and Blanc 1990; Le et al. 2006, although most recently, Parham et al. 2006, made a case in its support); *Scincella* for the Pakistani *Asymblepharus* (see Eremchenko and Szczerbak 1980); *Ptyas mucosus* for *P. mucosa* (see David and Das 2004); *Pelamis platurus* for *P. platura* (fide Lanza and Boscherini 2000); and *Praescutata* for *Thalassophis* (see McDiarmid et al. 1999). Khan (1998, 1999a, 1999b) described four taxa of scolecophidians that Wallach (2000) showed to be poorly diagnosed and incorrectly named. Nonetheless, both in the present volume and in a recent paper (Khan 2005a), the author continues to use the names as valid without justification, but corrects the names of the new taxa.

The 14-page bibliography captures most of what has been published on the regional herpetofauna. Missing are a number of works on the fauna of adjacent Afghanistan (such as Sharma 1976; Kuch 2004), neighboring areas of India, especially Kashmir, Rajasthan, and Gujarat (e.g., Krishna and Dave 1960; Sharma and Sharma 1975; Sahi and Duda 1985; 1986; Sahi et al. 1996; Daniel and Shull 1964; Daniel 2002) and China (e.g., Pope 1935; Zhao and Adler 1993). For the sake of completeness, I would like to add to this list the following references relevant to the herpetology of Pakistan: Adler et al. (2000), Alcock (1898), Anderson and Leviton (1966), Annandale (1906a, 1906b), Auffenberg (1988, 1994), Auffenberg and Rehman (1995), Auffenberg et al. (1989, 1990), Baig and Böhme (1991), David et al. (1999), Dowling (1993), Eremchenko (1987), Finn (1898), Gritis and Voris (1990), Helfenberger (2001), Leviton and Anderson (1970), Malnate (1960; 1962), Mertens (1953, 1954), Singh (1991), Smith (1933), Stemmler (–Gyger) (1969), Stickel (1951), Stoliczka (1872), Szczerbak (1991), Utiger et al. (2002), Waltner (1991), and Wüster and Thorpe (1992).

Species accounts vary in size, and are typically over a page in length, and include the current scientific name and authority, the original description, type locality information, diagnosis, color, natural history notes, and distribution. Conveniently for readers, a color image of the species and distribution map is set alongside the species account. After the species accounts are: Chapter 8 ('Distribution and Affinities of Herpetofauna'), Chapter 9 ('Herpetology of Habitat Types'), Chapter 10 ('Altitudinal Distribution of the Herpetofauna of Pakistan'), Chapter 11 ('Snakebite Problem in Pakistan'), Chapter 12 ('Threats to the Herpetofauna of Pakistan'), and finally, the bibliography and two pages of 'Suggested reading.' The work concludes with the index, which is in the form of a useful table, allowing species accounts, images, distributional maps, and figures to be found separately.

The author and copy editor at Krieger deserve congratulation for not letting too many typos and other mistakes slip by, and I noticed only a few: Rafiuesque for Rafinesque (page 1), *Sphaeroteca* for *Sphaerotheca* (pages 1, 8, 66, 67 et seq.), *Teratoscincus* Strauch, 1863 is not set in bold face (page 3), *Uromastyx asmussi* for *Uromastyx asmussii* (pages 3 and 174), *Stutiger* for *Scutiger* (page 52), squamata for Squamata (page 291), texa for taxa (page 295), and 1874 for 1884, for an early book on the topic by Murray (1884).

Krieger Publishing has produced a large number of herpetological titles in the last 20 years. To be fair to this publisher, the titles published would perhaps not be entertained by most publishers because of their limited market. On the other hand, this and all other works are overpriced (this particular volume, at its retail price a staggering 20% of Pakistan's current annual per capita income) and can be improved on in terms of color separation, choice of images, and photo editing. The price factor alone will keep the volume away from the hands of those who need the volume most. A number of images will appear familiar to readers as they are printed from the original Kodachromes by Sherman Minton (and reproduced in black-and-white in his 1966 work).

In summary, I recommend Khan's new offering to all interested in the fauna of the Subcontinent or those of West Asia, although I guess only those who can fork out US $145 (plus postage) can afford to possess a personal copy.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address). To submit a manuscript to ***HR***, please consult the SSAR webpage at:

<http://www.ssarherps.org/pages/HRinfo.php>

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution or Natural History notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order form will be sent prior to publication. These are also available upon request from the Editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR web page (http://www.ssarherps.org/pdf/Adrates.pdf).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at WCSU, Department of Biology, 181 White Street, Danbury, CT 06810, USA. Periodicals postage paid at Danbury, CT 06810 and at additional mailing offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Breck Bartholomew, PO Box 58517, Salt Lake City, UT 84158, USA. Please notify Breck Bartholomew, SSAR Publications Secretary (contact information below), regarding missing or damaged issues.

SSAR Publications

SSAR publishes seven different series: *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Contributions to Herpetology, Herpetological Circulars, Herpetological Conservation*, and the *Catalogue of American Amphibians and Reptiles* (see below for CAAR details). SSAR members receive pre-publication discounts on all *Facsimiles* and *Circulars* and on volumes in the *Contributions* and *Herpetological Conservation* series. A complete pricelist of Society publications is available at: <http://www.herplit.com/SSAR/>

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 760		US $460
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$6
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$6
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 760	$320

To order: make checks payable to "SSAR" and mail to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, Utah 84158, USA (fax 801/453-0489). e-mail: ssar@herplit.com.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 37, Number 1 (March 2006).

CAUDATA

AMBYSTOMA TIGRINUM MAVORTIUM (Barred Tiger Salamander). **EXTRALIMITAL POPULATIONS**. The natural range of *Ambystoma tigrinum mavortium* extends from central Nebraska to south Texas, USA (Conant and Collins 1991. Reptiles and Amphibians Eastern and Central North America, Houghton Mifflin Co., Boston, Massachusetts). The common practice of using Tiger Salamander larvae (water dogs) as fish bait has resulted in introductions of *A. t. mavortium* beyond its natural range (Petranka 1998. Salamanders of the United States and Canada, Smithsonian Press, Washington 587 pp.).

We report extralimital populations of *A. t. mavortium* from the unincorporated communities of Alpine and Ramona, San Diego Co., California. We consider both populations to be established because of the documentation of larvae (Alpine) or recently transformed individuals (Ramona). Specimen vouchers from the Alpine population have been deposited in the herpetological collection of the California Academy of Science, San Francisco, California (CAS). Vouchers were also sent to H. Bradley Shaffer, Department of Zoology, University of California, Davis, California, for genetic analysis.

On 6 February 1996, *A. t. mavortium* larvae (ca. 30 mm TL) were first detected in the vicinity of upper Chocolate Canyon in the unincorporated community of Alpine (R2E T15S Sec 29). Subsequent surveys resulted in additional observations of *A. t. mavortium* larvae: Spring 1996 (ca. 35 mm TL); 16 March 2001 (ca. 25 mm TL; CAS 233270); 28 March 2003 (ca. 17 mm TL; CAS 233721); 4 April 2003 (ca. 35 mm TL; CAS 233274); 4 May 2003 (ca. 43mm TL); April 2004; and 12 March 2005 (ca. 50mm TL; CAS 233723). Three of the larvae collected in 2003 were maintained in aquaria and photographed 25 months later to determine the pattern and coloration of individuals representing this population. Additional locality records of *A. t. mavortium* within the town of Alpine include a surface-active adult taken during Winter 1994 (R2E T15S Sec. 32), another on 12 January 2005 (R1E T16S Sec. 11), as well as the excavation of an adult from a residential garden in Spring 1999 (R2E T15S Sec. 33). Although no specimens were collected from these three additional locations, both surface-active individuals were photo documented. The Alpine population is now known to occupy an area of both the San Diego River watershed having been found in the area of upper Chocolate Canyon, and the Sweetwater River watershed, occurring in an unnamed drainage along Harbison Canyon Road.

Additional records of *A. t. mavortium* within San Diego Co. include three individuals captured within a few meters of the West Branch drainage located southeast of the unincorporated community of Ramona (R1W T13S Sec. 36). In Spring 2002, an adult was captured, and during Spring 2003, on separate dates, a recently transformed individual and an adult were captured. Individuals were photo documented prior to being released at the places of capture. This population also occurs within the San Diego River watershed.

Due to the limited amount of information, aspects of these populations such as source of introduction, length of time as an established population, population size, and the extent of their distribution remain unresolved.

This note provides source information for the *A. tigrinum* population of Alpine, San Diego Co., represented on the range map (extreme southwest portion of mainland California) in Stebbins (2003. Western Reptiles and Amphibians, 3rd. ed., Houghton Mifflin Co., Boston, Massachusetts), as referenced in Jennings (2004. An Annotated Check List of the Amphibians and Reptiles of California and Adjacent Waters, California Dept. Fish and Game 90[4]:161–213), and in Lemm (2006. Field Guide to Amphibians and Reptiles of the San Diego Region. University of California Press. Berkeley, California).

We extend our thanks to Mark R. Jennings for making useful comments on this manuscript, and Carlton Rochester, Drew Stokes, Gale Bustillos, and Yolaine Stout for providing additional information for Alpine locations, and Kyle Icke, Rick Roedell, and Jim Davidson for the Ramona location.

Submitted by **EDWARD L. ERVIN**, Merkel and Associates, Inc., 5434 Ruffin Road, San Diego, California 92123, USA; and **TIMOTHY R. BURKHARDT**, 49 Blossom Lane, San Rafael, California 94901, USA.

AMBYSTOMA TIGRINUM TIGRINUM (Eastern Tiger Salamander). **BURROW DESCRIPTION.** Relatively little is known about burrows of the Eastern Tiger Salamander (Semlitsch 1983. Can. J. Zool. 61:616–620; Madison and Ferrand III 1998. Copeia 1998:402–410; Gruberg and Stirling 1972. Herpetol. Rev. 4:85–89). During winter 2005, we radio-instrumented four *A. t. tigrinum* as they exited a breeding wetland in southwest Georgia, USA. In all instances, animals were tracked to underground burrows with one or more visible entrances. The area and depth of burrows were measured when we attempted to recover the transmitters; measurements varied considerably among individuals.

One radio-tagged female was located in a burrow seven days after release. The burrow was adjacent to an agricultural field and firebreak, and was 6 m from the base of a large live oak, *Quercus virginiana*. The burrow meandered through an area ca. 0.5 × 0.50 m and reached a maximum depth of 0.30 m. Only one entrance was found; the burrow terminus was an elliptical cavity.

A tagged male was also located seven days after release. It spent two days in a shallow, branched burrow network. Total burrow length was ca. 4 m with a total area of 1.0 × 3.5 m. Although most of the tunnels were shallow, the burrow reached a maximum depth of 0.20 m. There was no tree canopy over the burrow system and

the burrow system was 13 m from the base of the nearest live oak. There were small oaks (*Quercus* spp.) in the area immediately surrounding the burrow.

A second tagged male was tracked to a burrow three days after release. It spent at least two days at this location and was observed once in the entrance of the burrow. The burrow was surrounded by shrubs and small oaks in the understory with a large, mature hardwood overstory. Burrow area was 1.0 × 1.5 m and was at least 0.40 m deep. The burrow led to a thick root bed.

The third tagged male was tracked to a burrow network the day after release and spent at least four days at this site. The burrow system was adjacent to a firebreak and agricultural field with little or no vegetation. The burrow network was shallow (< 3 cm) and covered an area 3.0 × 5.0 m with more than 10 different tunnels leading to openings at the surface. We tracked this animal over a 2 h period (2100–2300 h) in February and found that it moved throughout the burrow network.

Submitted by **SEAN C. STERRETT, DAVID A. STEEN,** and **LORA L. SMITH,** Joseph W. Jones Ecological Research Center, Route 2 Box 2324, Newton, Georgia 39870, USA (e-mail: ssterret@jonesctr.org).

DESMOGNATHUS MONTICOLA (Seal Salamander) and ***DESMOGNATHUS QUADRAMACULATUS*** (Black-bellied Salamander). **INTRAGUILD PREDATION** (IGP) and **AUTOUROPHAGY**. Although experimental studies demonstrate that plethodontid salamanders are intraguild predators, there are few records from nature of interspecific predation by salamanders. A previous note (Bernardo 2002. Herpetol. Rev. 33:121) reported three distinct IGP interactions involving six different plethodontid species in the field. Here we document a fourth distinct IGP interaction involving a new pairing and one additional species. Upon arrival at a waterfall in Union Co., Georgia (USA) on 13 May 2005, we observed a large (ca. 70 mm SVL) *Desmognathus monticola* with what appeared to be its own recently autotomized tail in its mouth (Fig. 1). As we puzzled over this observation for a few moments, the salamander backed under a large rock into a burrow. We then noticed a freshly dead subadult *Desmognathus quadramaculatus* (ca. 40–50 mm SVL) about a meter away from where we had observed the *D. monticola*. The smaller individual had recently sustained significant injuries and was dead. It was missing its right hind limb, its tail, and it had a fresh bite mark along the left side if its trunk (Fig. 2); the bite penetrated the skin revealing musculature (circled in Fig. 2), and the wounds to the limb and tail were fresh and bloody. We presume that the missing body parts were consumed by the *D. monticola*, although we were unable to capture it. From these observations we conclude that the two salamanders had a predatory encounter. The larger individual also apparently sustained an injury causing it to autotomize its tail. Tail autotomy is common among salamanders during predatory interactions (Bernardo and Agosta 2005. Biol. J. Linn. Soc. 86:309–331). The other noteworthy feature of this interaction is the apparent retrieval and planned consumption of its own autotomized tail by *D. monticola*. Tail autotomy during predatory encounters has been shown to increase survival, but because tails are generally highly nutritious, tail loss also may impinge on reproductive phenotypes and other fitness components (Bernardo and Agosta 2005, *op. cit.*). Autourophagy permits recovery of these valuable resources when the predator fails to eat the tail. This behavior has been documented in lizards (e.g., Clark 1971. J. Exp. Biol. 176:295–302), but we are unaware of any records of tail recovery and ingestion by salamanders.

FIG. 1. Adult *Desmognathus monticola* consuming its own tail following a predatory event with a sub-adult *D. quadramaculatus*.

FIG. 2. Deceased sub-adult *Desmognathus quadramaculatus*, showing significant injuries apparently sustained during a predatory event with a larger *D. monticola*. Circled area denotes exposed musculature; note also missing left rear leg and tail.

DICAMPTODON COPEI (Cope's Giant Salamander). **PREDATION.** *Dicamptodon copei*, restricted in distribution to western Washington and northwestern Oregon, is ecologically poorly known (Jones et al. 2005. Amphibians of the Pacific Northwest. Seattle Audubon Society, Seattle, Washington. 227 pp.). Few specific dietary data exist. Antonelli et al. (1972. Northwest Sci. 46:277–289) reported prey in 2 arachnid groups; 2 fish genera; 2 mollusc groups at an ordinal level; and 8 insect orders at a family level, including a gryllid orthopteran adult; but precisely which of these are *D. copei* prey is unknown because the data are a composite from *D. copei* and *D. tenebrosus*. In a general account, Nussbaum et al. (1985. Amphibians and Reptiles of the Pacific Northwest. University of Idaho Press, Moscow. 332 pp.) reported

that *D. copei* "feed on almost all available aquatic organisms small enough to be ingested," adding that "immature insects form the bulk of the diet;" their comments on prey taxon specificity were restricted to the statement that "fish eggs, small fish, eggs and tadpoles of [Coastal] Tailed Frog (*Ascaphus truei*), and smaller larvae of their own kind and the Pacific Giant Salamander [*D. tenebrosus*] are also eaten." Hence, we augment the sparse species-specific dietary data on this species with an observation of *D. copei* from southwestern Washington with orthopteran prey.

On 12 Sept 2001 at 1459 h, DJD and RFP encountered a 73 mm SVL (13.5 g, 65 mm tail) paedogenic *D. copei* that was submerged under a cobble sitting on gravel in a small step-pool (30 cm max depth) in a small (0.6 m average width) headwater stream. The *D. copei* was found in a second-order reach in a late-rotation age Douglas-fir (*Pseudotsuga menziesii*) forest managed for timber in the Stillman Creek Basin, Willapa Hills (46°28'51.70"N, 123°12'45.67"W, WGS 84; elev. 639 m). When first found, the *D. copei* had part of an orthopteran hindlimb protruding from its mouth. In the process of handling the *D. copei* for measurement, the intact hindlimb was removed and found severed at the articulation point of the femur with the body. Viscous fluid clung to its severed end. We preserved the disarticulated leg and released the *D. copei* at its site of capture.

Identification of the orthopteran leg revealed it to be the left hind leg of a camel cricket, *Tropidischia xanthostoma* (Rhaphidophoridae; Orthoptera). Rhaphidophorids, a cosmopolitan family of hygrophilic omnivorous orthopterans with many cavernicolous species (Vandel 1965. Biospeleology—The Biology of Cavernicolous Animals. Pergamon Press, London, England. 524 pp.), are a group we have often observed in the coastal Pacific Northwest landscape. The orientation of the leg (head of the femur inside the salamander) leads us to believe that the *D. copei* ate the remainder of the cricket. This represents the first record of a *D. copei* consuming a rhaphidophorid cricket.

The Weyerhaeuser Company, through Douglas Runde, facilitated work on their lands, Washington Department of Fish and Wildlife funded the surveys, and David A. Nickel (Systematic Entomology Lab., Agriculture Research Service, USDA, Beltsville, Maryland) identified the cricket.

DICAMPTODON TENEBROSUS (Pacific Giant Salamander). **DEFENSE.** In the Pacific Northwest, *Dicamptodon* spp. are the largest salamanders having both terrestrial and neotenic forms (Petranka 1998. Salamanders of the United States and Canada, Smithsonian Institution Press, Washington and London. 587 pp.). They also are an important food source for garter snakes (*Thamnophis* spp.) which, as they grow in size, increasingly prey on larger salamanders (Lind and Welsh 1990. J. Herpetol. 24:104–106; Lind and Welsh 1994. Anim. Behav. 48:1261–1273). Although this behavioral trend is hypothesized to increase snake survival (Lind and Welsh 1994, *op. cit*), large terrestrial *Dicamptodon* spp. can pose a significant threat to predatory garter snakes. Diller (1907. Science 26:907–908) observed a terrestrial giant salamander firmly grasping the head of a garter snake with its jaws for several hours, which resulted in the death of the snake; and Graf (1949. Copeia 79–80) made a similar observation, but the snake was eventually released by the salamander. Here, we present a description of a terrestrial *D. tenebrosus* engaged in a fight with an adult California Red-sided Garter Snake (*Thamnophis sirtalis infernalis*) over a half-century since the last published report of a similar event.

On 14 April 2001 at 1500 h, in an old-growth redwood forest at Montgomery Woods State Park, Mendocino Co., California, USA (39°13'46.2"N, 123°23'22"W), SVS encountered a *D. tenebrosus* (ca. 17.5 cm TL) biting the head of a *T. s. infernalis* (ca. 75 cm TL, largest diameter ca. 3.75 cm). The salamander was biting the snake head-on, possessing the entire upper cranium posterior to the eyes and up to the dorsal stripe in its jaws. The snake's head was extremely flattened, disarticulated, and bloodied from the salamander's bite. Initially, the snake was vigorously thrashing side-to-side, coiling, and trying to pin the salamander to free itself. In response, the salamander moved and rolled with the action of the snake, righting itself every time without releasing its grip. By 1545 h the snake showed reduced activity, having spent much of its energy trying to escape the salamander, and was still bleeding profusely from the head. Following 45 min of observation, SVS left the area. At 1745 h, SVS returned to the area and found the salamander still maintaining its grip on the snake in the same position as first discovered. Although the snake was still alive, it was extremely lethargic and appeared close to death. Unfortunately, due to waning daylight, SVS departed the area and did not return to investigate the outcome of the fight.

We assume that antagonistic encounters like this occur as a result of snakes actively pursuing salamanders. Although formal accounts of interactions between *Thamnophis* spp. and terrestrial *Dicamptodon* spp. are few (Diller, *op. cit.*; Graf, *op. cit.*), we suspect these types of events are probably common, though rarely observed. Most accounts of active predation of *Dicamptodon* spp. by *Thamnophis* spp. have been largely relegated to larval or neotenic salamanders occupying aquatic habitats where they occur at high densities and are more readily observed (Lind and Welsh 1990, 1994, *op. cit.*). Future demographic research on giant salamanders is needed to better understand their terrestrial ecology and interactions with potential predators such as garter snakes.

Submitted by **SALVATORE V. SILVESTRI, JR.,** and **ROBERT B. DOUGLAS**, Wildlife, Watershed, and Fisheries Department, Mendocino Redwood Company, P.O. Box 489/32600 Holquist Lane, Fort Bragg, California 95437, USA; e-mail: (SVS): ssilvestri@mendoco.com; (RBD): rdouglas@mendoco.com.

PLETHODON VEHICULUM (Western Red-backed Salamander). **REPRODUCTION**. On 2 Aug 2002, we found a nest of the Western Red-backed Salamander, *Plethodon vehiculum*, 80 m from the southern bank of the lower Pachena River (48°48'25"N, 125° 06'28"W), in a Sitka Spruce floodplain forest (> 250 years old), ca. 4 km from the town of Bamfield, Vancouver Island, Brit-

ish Columbia. While searching for earthworms, we dug with our hands into loose moss, litter, and humus at the base of a decayed tree stump. We uncovered a clutch of 12 eggs within a small hollow created by the root of a hemlock sapling and a piece of decayed wood (12 × 5 × 1.5 cm) about 10 cm under the surface. The grape-like cluster of eggs was enclosed in a gelatinous membrane with a stalk attached to the underside of the wood. We noted the presence of an adult who crawled further underground before we could verify its identity. We quickly replaced the nest to its original position.

We revisited the site on 19 Aug 2002 to photograph the nest (photographs of the nest and accompanying adult were deposited in the Royal British Columbia Museum image database). We estimated adult SVL to be > 50 mm but did not handle the individual for exact measurements. The large size suggests that the adult was likely a female. Eyes and small legs were visible within each egg. One egg was 0.56 cm in diameter. On 29 Sept 2002, we returned to the site and found only a small gelatinous lump on the wood. The substrate appeared as we had left it.

This nest description is noteworthy for two reasons. First, only two other natural nests of *P. vehiculum* have been documented in the literature. They were found 12 cm apart beneath a rock (40 × 30 × 15 cm) in talus at the base of a shear roadside basalt outcrop near Klickitat Lake, Oregon (Hanlin et al. 1979. J. Herpetol. 13:214–216). Leonard et al. (1993. Amphibians of Washington and Oregon. Seattle Audobon Society, Seattle. 168 pp.) suggested that nests and eggs of *P. vehiculum* are not well documented because most egg clutches are probably located well beneath the surface. The nest that we found was at a shallow depth under humus and wood, where it would be considerably more vulnerable to predation, desiccation, and soil compaction than would eggs in deeper nest sites. Second, this clutch of 12 eggs is notably larger than the clutches of 8 and 9 reported by Hanlin et al. (1979, *op. cit.*) and the clutch of 9 laid by a captive female (Stebbins 1951. Amphibians of Western North America. Univ. California Press, Berkeley. 539 pp.). It is within the high end of the range reported for ovarian clutches (6–19 eggs per clutch; mean = 10.43; N = 65) for the species in Oregon (Peacock and Nussbaum 1973. J. Herpetol. 7:215–224). The adult associated with the nest was within the range of females measured on Vancouver Island (42–58 mm SVL; Ovaska and Gregory 1989. Herpetologica 45:133–143).

Submitted by **BARBARA A. BEASLEY** and **MIA PELLETIER**, Bamfield Marine Sciences Centre, Bamfield, B.C. Canada, V0R 3A0; e-mail (BAB): beasley@island.net.

PSEUDOTRITON RUBER RUBER (Northern Red Salamander). **SIZE AND SUBTERRANEAN AGGREGATION**. Conant and Collins (1998. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. 3rd ed., expanded. Houghton Mifflin, Boston. 616 pp.) reported 181 mm total length (TL) as the maximum size for *Pseudotriton ruber ruber*. Herein, we report an aggregation of exceptionally large *P. r. ruber* from a cave, many approaching the reported maximum size.

On 20 October 2005, 14 *P. r. ruber* were discovered in Anderson Spring Cave, a state-owned cave on Pigeon Mountain, Walker Co., Georgia, USA. All individuals were found underneath rocks in the cave stream, ca. 25–75 m beyond the twilight zone. Water depth of the stream ranged from 2–10 cm. Thirteen individuals were captured, measured to the nearest mm using a metric rule, and weighed to the nearest 0.5 g using a Pesola scale. The largest individual measured 113 mm SVL, 180 mm TL, and weighed 27.0 g. Three other individuals exceeded 110 mm SVL, 175 mm TL, and 25.0 g. Mean size ± 1 SD for the 13 captured individuals was 102.7 ± 7.6 mm SVL, 164.8 ± 11.1 mm TL, and 19.7 ± 4.4 g mass. The smallest individual from Anderson Spring Cave (92 mm SVL, 155 mm TL, 17.0 g) was larger than the largest individual (female 85 mm SVL) out of 316 specimens collected by Bruce (1978. Copeia 1978:417–423) in the southern Blue Ridge of North Carolina. A voucher photograph was taken of the largest individual and placed into the Herpetological Collection at Austin Peay State University (APSU 18055).

Female *P. ruber* grow larger than males (Bruce 1978, *op. cit.*); however, sex is difficult to determine externally. During autumn, females disappear from surface sites, presumably to brood eggs, and are not observed on the surface until late autumn or winter (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Inst. Press, Washington, DC. 587 pp.). Although adults are common in headwater springs and seeps (Hunsinger 2005. *In* M. Lannoo [ed.], Amphibian Declines: The Conservation Status of United States Species, pp. 860–862. Univ. of California Press, Berkeley and Los Angeles), *P. ruber* has infrequently been reported from caves. The salamanders observed in Anderson Spring Cave may represent a breeding aggregation of exceptionally large females. Males may also be present within the aggregation. The two largest individuals from Anderson Spring Cave were found brooding separate egg masses beneath the same rock, and another large female had ova visible through her venter. Communal nesting has not been documented in *P. ruber*, although Miller and Niemiller (2005. Herpetol. Rev. 36:429) observed presumably two females brooding an egg mass in the twilight zone of a cave stream in DeKalb County, Tennessee, in September 2004. Walker (1931. *In* Pfingsten and Downs 1989. Salamanders of Ohio. Ohio Biol. Surv. Bull. New Series Vol. 7 No. 2. 315 pp.) discovered 22 adults on 24 March within a few square meters in a spring in Knox County, Ohio, and suggested that the concentration may have been related to hibernation. Rather than hibernation, we suggest the aggregation may have been related to reproduction.

ANURA

ACRIS CREPITANS BLANCHARDI (Blanchard's Cricket Frog). **MORPHOLOGY.** Cricket Frog dorsal background color varies from light to dark gray or from light tan to dark reddish-brown (Milstead et al. 1974. Evolution 28:489–491). The vertebral stripe of *A. crepitans* is polymorphic, and can be a varying shade of red (red, brown, reddish brown), green, or gray (Pyburn 1961. South-

west. Nat. 6:164–167). According to Nevo (1973. Evolution 27:353–367), gray is most frequent, followed by red, and then green.

Some *A. crepitans* lack the prominent vertebral stripe and have completely green dorsal surfaces (Gray 1995. Trans. Illinois State Acad. Sci. 88:137–138; L. M. Blackburn, pers. comm.). This rare color pattern was observed during May–August 2004 and May–August 2005 at a semi-permanent wetland at Ford Lake Park in Ypsilanti, Michigan, USA. The *A. c. blanchardi* found at Ford Lake Park were similar to the specimens reported by Gray (1995, *op. cit.*): the green dorsal surface color was brighter than the olive or tan background color, and covered the head, body, limbs, and feet. About 76% (13/17) of the Cricket Frogs captured at Ford Lake Park exhibited this green color pattern. The wetland at Ford Lake Park has more emergent vegetation, which might provide a green color pattern background that matches the green dorsal surface of these Cricket Frogs. Cricket Frog coloration might be an adaptation to predation, as coloration that matches substrate color allows Cricket Frogs to vanish as soon as they stop moving (Milstead et al. 1974. *op. cit.*). Nevo (1973. *op. cit.*) suggested that color morph frequency might differ between neighboring microhabitats based on substrate color. Frequencies of red and green morphs varied significantly with the substrate color of the pond, which could be due to selective predation and/or habitat selection by morphs (Nevo 1973. *op. cit.*). To the best of my knowledge, this is the first recorded account of the green color pattern variant in Blanchard's Cricket Frogs in Michigan.

ACRIS CREPITANS BLANCHARDI (Blanchard's Cricket Frog) **PREDATION.** Known predators of the Northern Cricket Frog (*Acris crepitans*) include frogs, fish, snakes, turtles, birds, and mammals (Gray and Brown. 2005. *In* Lannoo [ed.], Amphibian Declines: The Conservation Status of United States Species, pp. 47–54. University of California Press, Berkeley). The only previously recorded anuran predator of *A. crepitans* is the American Bullfrog (*Rana catesbeiana*) (Lewis 1962. Trans. Illinois State Acad. Sci. 55:80–83). Here I report predation of a juvenile Blanchard's Cricket Frog (*Acris crepitans blanchardi*) by an adult Green Frog (*Rana clamitans*). To the best of my knowledge, this represents the first record of predation by a *R. clamitans* on a Cricket Frog.

Although *R. clamitans* are commonly associated with *A. crepitans*, there are no published records of Green Frog predation on Cricket Frogs (Hay 1998. *In* Lannoo [ed.], Status and Conservation of Midwestern Amphibians, pp. 79–82. University of Iowa Press, Iowa City). Green Frogs eat insects, slugs, snails, crayfish, spiders, flies, caterpillars, butterflies, moths, small snakes, and frogs (Jenssen 1967. Copeia 1967:214–218). I observed an adult *R. clamitans* capture and consume a juvenile *A. c. blanchardi* on 17 Aug 2005, between 1530–1540 h along the shoreline of a permanent wetland at the Port Huron State Game Area in Port Huron, Michigan, USA. Although I noticed the legs of the *A. crepitans* dangling from the mouth of the *R. clamitans*, I did not notice a struggle by the Cricket Frog to free itself. After capturing the Cricket Frog in its mouth, the Green Frog jumped away and consumed its prey. The Blanchard's Cricket Frog is declining at an alarming rate in the northern portions of its range, and the exact cause of this decline is unknown (Harding 2000. Amphibians and Reptiles of the Great Lakes Region. Univ. Michigan Press, Ann Arbor). Hay (1998, *op. cit.*) speculates that the association between *R. clamitans* and *A. crepitans* might be partially responsible for Cricket Frog declines. Information on predators and Cricket Frog mortality can assist researchers in determining the cause of these declines and suggest management techniques to conserve the species.

Thanks to Ernie Kafcas at the Michigan Department of Natural Resources for access to Port Huron State Game Area.

ALSODES GARGOLA (Rana del Catedral). **PREDATION.** Predation by Odonata naiads on anuran larvae is a major cause of tadpole mortality (Heyer et al. 1975. Biotropica 7:100–111). However, it has not been reported under natural conditions on anurans of Patagonia. Here we present the first record of predation by Odonata naiads on tadpoles of the frog *Alsodes gargola*, which is endemic to northwest Patagonia, Argentina. *Alsodes gargola* inhabits oligotrophic high altitude lakes and mountain streams (200–2000 m elev.). Adults and juveniles are highly aquatic, although they may also live in terrestrial environments near water. *Alsodes gargola* tadpoles have a long larval period and overwinter at least one year (Logares and Úbeda 2004. Herpetol. Rev. 35:368–369), therefore the species is only associated with permanent aquatic environments, where different tadpole cohorts typically coexist.

During a study of the *A. gargola* tadpole population (2004–2005) in aquatic mountain environments in Nahuel Huapi National Park, Río Negro Province, Argentina, we monitored the population in a stream in Valle de los Perdidos (41°14'32"S; 71°16'7"W, 1375 m elev.), surrounded by a mosaic of deciduous *ñire* (*Nothofagus antarctica*) thicket, altitudinal steppe, and hygrophilous meadow (*mallín*). The normal regional rainfall pattern causes this stream to carry noticeably less water towards the end of the austral summer. In April 2005 (austral autumn) it began to rain later than usual and the level of the stream dropped so far that its flow was interrupted, forming long, isolated pools of water where the tadpole population was temporarily confined. On 2 April, many of the tadpoles showed signs of attack on their bodies. No evidence of predation had been recorded previously. Various nymphs of *Rhionaeschna variegata* Fabricius (Odonata, Anisoptera, Aeshnidae) naiads, measuring 8–35 mm, were found in the pools. *Rhionaeschna variegata* is the most ubiquitous, widely distributed Anisoptera species in Patagonia. It is found to Tierra del Fuego, where it is the only Odonata species (Muzón 1995. Rev. Soc. Entomol. Argent. 54:1–14). Exuvia were found on the shore, providing evidence of recent metamorphosis. Tadpoles from two isolated pools were analyzed: Pool 1 (length 2.3 m; max. mean depth 0.33 m; volume 2.1 m^3) and Pool 2 (length 4.3 m; max. mean depth 0.61 m; volume 1.3 m^3). The entire tadpole population was sampled at the beginning

of austral summer (23 Dec 2004) and the beginning of austral autumn (2 April 2005). The total length of each tadpole was measured and the developmental stage determined (Gosner 1960. Herpetologica 16:183–190). The percentage of injured tadpoles was calculated, and the location of the injuries on the body recorded (tail vs. head-trunk). For each pool, initial abundance (N_0) and final abundance (N_1) data were used to calculate mortality $[(N_0-N_1)/N_0]\times100$.

To confirm these attacks, *R. variegata* naiads (14–35 mm) and *A. gargola* tadpoles (40–66 mm) were returned to the laboratory, and after acclimatization for 48 h at 18°C, were placed in different combinations of sizes in polyethylene containers containing dechlorinated water and suspended roots of stream plants. Observations were made for 7 full days, at a constant temperature of 18°C and a natural light-and-dark regime.

In the laboratory, the tadpoles placed in the containers with the naiads did not exhibit evasive behavior or avoid contact. After 36 h, all naiads larger than 26 mm repeatedly attacked tadpoles of all sizes, and this behavior persisted throughout the period of observation. The most active times were dawn and dusk. The tadpoles managed to escape from most attacks, although they were sometimes injured. Injuries of the abdomen were always fatal, while no attack on the tail led to tadpole death. Naiads fed first on the tadpole abdomen. Large naiads (≥ 34 mm) succeeded in killing large tadpoles (66 mm). The remaining carcasses (remains of cartilage and musculature) and the type of injuries observed allow us to assume that the carcasses observed in the field were the result of naiad predation. In the laboratory, the *Rhionaeschna variegata* naiads were noticeably voracious, and able to attack and eat tadpoles twice their size, using the "sit and wait" hunting strategy (resting concealed in submerged vegetation waiting for the prey to pass) which is typical of this species (Gullan and Cranston 1994. The Insects. An Outline of Entomology. Chapman and Hall, London, 491 pp.).

The tadpoles collected were at stages 25–40 (Gosner, *op. cit.*), and belonged to different cohorts. In Pool 1, we counted 113 tadpoles during the first sampling (density: 55 tadpoles/m^3), and 90 at the second sampling (density: 45 tadpoles/m^3). In addition, 215 newly hatched tadpoles were recorded. In Pool 2, we counted 66 tadpoles at the first sampling (density: 51 tadpoles/m^3), and 28 at the second sampling (density: 21 tadpoles/m^3). There was no recruitment of new larvae. During the second sampling (austral autumn), tadpoles of all stages showed signs of attack with recently inflicted, bleeding injuries or injuries in the process of healing. Mortality in the population attributable to naiad predation was 20.3% in Pool 1 and 57% in Pool 2, over a period of 101 days. In Pool 1, 62 tadpoles (20.3 %) had injuries: 61 on the tail and only 1 on head-trunk. In Pool 2, 17 tadpoles (60 %) had injuries: 8 on the tail and 9 on head-trunk. On two visits to the site, 14 and 21 days later, fewer naiads were found perching on the submerged roots, and exuvia were found outside the water. Many of the injured tadpoles were found to have healed completely, judging from the presence of whitish scar tissue.

Because of its long larval stage, *A. gargola* is limited to permanent water bodies. In its pristine environments, the species has no native vertebrate predator. Furthermore, in its alpine aquatic environments (above the tree line) no arthropod predator is known. However, in streams at lower altitudes, *A. gargola* tadpoles might coexist with Odonata naiads. When these streams carry a normal amount of water, attacks must be rare, judging by the lack of injured tadpoles observed. But under exceptional environmental conditions, such as the ones reported here (summer–autumn drought), which leads to atypical confinement in still waters, there is a greater likelihood of *A. gargola* tadpoles encountering *Rhionaeschna variegata* naiads, and the tadpoles become highly vulnerable to predation. Thus, during very dry years, the tadpole population confined to pools may face high levels of predation, and suffer high percentages of mortality. These are the only losses recorded for *A. gargola* in pristine environments (without exotic fish species).

Further studies are needed to elucidate the atypical though intensive role of predation by Odonata naiads as predators in the dynamics of the *A gargola* tadpole population in streams subject to large fluctuations in the flow of water or during exceptionally dry years.

We thank J. Muzón and M. Kun for identifying the Odonata naiads.

APLASTODISCUS ARILDAE (Green Tree Frog). **PREDATION.** Spiders might be among the most important predators of frogs (Hayes 1983. Biotropica 15:74–76). Numerous reports have been published on members of the family Pisauridae (*Thaumasia* and *Dolomedes*) feeding on adult hylid frogs (Bastos et al. 1994. Herpetol. Rev. 25:118; Pramuk and Alamillo 2002. Herpetol. Rev. 33:46–47; Marra et al. 2003. Herpetol. Rev. 34:55; Jeffery et al. 2004. Herpetol. Rev. 35:158). These spiders are often found near watercourses, a habitat shared with members of the closely related family Trechaleidae (Carico 1993. J. Arachnol. 21:226–257). On 20 Nov 2005 at 2320 h in Serra do Japi (23°11'S; 46°52'W; 1030 m), municipality of Jundiaí, State of São Paulo, Brazil, an adult female trechaleid spider (*Trechaleoides biocellata*) was observed on rocks close to the water and 1.2 m from a male *Aplastodiscus arildae* (SVL 35.6 mm; mass 2.3 g). The treefrog was calling on a leaf of a bush 1.1 m high at the edge of a stream. Forty- five minutes later, the same spider was found with the frog partially digested in its chelicerae at the same site where the frog was observed earlier. A voucher specimen of *T. biocellata* collected at the same site was deposited in the spider collection of Instituto Butantan, São Paulo, SP (IBSP 59522).

We are grateful to FAPESP (Proc. 01/13341-3) and CAPES for financial support.

ATELOGNATHUS PATAGONICUS (Rana Acuática de Laguna Blanca). **OVERWINTERING TADPOLES.** Only one anuran species (*Alsodes gargola*) from Patagonia, Argentina has been reported to have tadpoles overwinter (Logares and Ubeda 2004. Herpetol. Rev. 35:368–369). Herein we report overwintering tadpoles of *Atelognathus patagonicus,* an endangered anuran from the northwest Patagonian steppe of Argentina. This semi-aquatic frog is endemic to the endorrheic wetland system of Laguna Blanca National Park and surrounding areas (Neuquén Province, Argentina). *Atelognathus patagonicus* is extinct from the largest lake in the system (Laguna Blanca, 1780 ha), restricting its presence to 21 neighboring smaller bodies of water (surface area between 0.5 and 60 ha). The objective of this study was to compare monthly overwintering tadpole stages in the most representative microhabitats of a permanent pond.

From January to December 2004 we studied the larval phenology of *A. patagonicus* in a permanent lagoon, Laguna Verde (20 ha) and in a temporary pond, Laguna Batea (2 ha). Both are located in Laguna Blanca National Park and close to Laguna Blanca. Overwintering tadpoles were only detected in the permanent lagoon (Laguna Verde, 39°00'28"S, 70°23'07"W; elev. 1250 m). During the winter, Laguna Verde is characterized by the presence of ice, with frequent snowstorms and southwest wind gusts to 140 km/h. Annual rainfall is < 360 mm and the most extreme air temperatures recorded were -23°C in July 2000 and 34.5°C in February 2002 (period 1999–2003).

The following results were obtained from June to August 2004, when the harshest winter climatic conditions and the lowest temperatures were reported. Water temperature was recorded every hour using a Data Logger Hobo Water Temp Pro and data were analyzed using Box Car Pro 4. The minimum mean monthly water temperature was recorded in July (2.8°C). The shoreline was sampled selecting the most representative microhabitats: a) coarse fragments (gravel, boulder and bedrock), b) mix (gravel and sand), and c) fine sediment (dominated by sand). Tadpoles were captured using aquatic funnel traps (30 cm long and 11 cm diam), and body length and Gosner stage was determined (Gosner 1960. Herpetologica 16:183–190). All tadpoles were returned unharmed to their original capture site. Traps were placed parallel to the shoreline at 20–80 cm depth with 5 m interval between each one in each microhabitat. Because of the harsh climatic conditions, the number of traps set per month and per microhabitat differed (June = 90 traps/total, 30 traps/microhabitat; July = 39 traps/total, 15 traps/microhabitat a and c, and 9 traps/microhabitat b; August = 42 traps/total, 15 traps/microhabitat b and c, and 12 traps/ microhabitat a. Traps were left in place overnight.

During the entire study, 114 *A. patagonicus* tadpoles were captured at Gosner Stage 35–41 (Gosner 1960, *op. cit.*), which included individuals belonging to two cohorts (embryos hatching during early and late summer). No differences were found in the Gosner stage between months ($\chi^2 = 0.63$, 2 df, P = 0.73). Total length of the entire series ranged from 21–31.6 mm SVL; mean body length was 26.16 ± 0.5 mm. Captures were more abundant in July (N = 63; mean/trap = 1.61) than June (N = 12; mean/trap = 0.13) or August (N = 39; mean/trap = 0.93). Significant differences in the number of individuals by microhabitat ($\chi^2 = 65.27$, 4 df, P <0.001) and no differences in the stages between each microhabitat ($\chi^2 = 1.00$, 2 df, P = 0.61) were found. Tadpoles were more abundant in microhabitat a (N = 88; mean/trap = 1.54) than in microhabitat b (N = 20; mean/trap = 0.37) and than in c (N = 6; mean/trap = 0.13).

Few published observations of overwintering tadpoles come from the Northern Hemisphere and there is only one published account in southern South America (Logares and Úbeda, *op. cit.*). Herein we report the first data for overwintering tadpoles in relatively low altitudes of the Patagonia steppe, Argentina. *Atelognathus patagonicus* tadpoles showed two overwintering cohorts, suggesting that individuals can metamorphose at two different rates. Despite the extreme climatic conditions of winters, Patagonian steppe summers are almost four months long, allowing tadpoles to take advantage of the high seasonal productivity during warm summers. As in other amphibians, the ability of larvae to overwinter could be an adaptation to the harsh climatic conditions that characterize the Patagonian steppe.

This information is important because of the paucity of natural history data for this species (Cuello 2002. *Atelognathus patagonicus* (Anura, Leptodactylidae): distribución, hábitat, fenología y estado de conservación en el Parque Nacional Laguna Blanca y sus alrededores. Licenciature Thesis, Univ. del Comahue, Bariloche, Argentina 87 pp.; Fox et al. 2005 Copeia 2005:921–929) and its conservation status. *Atelognathus patagonicus* is listed as Endangered (IUCN 2004) and "In danger of extinction" (Secretaría de Medio Ambiente, Argentina, 2004).

BARYCHOLOS TERNETZI (Chimbo Frog). **PREDATION.** Amphibians are common prey for a great variety of vertebrates, arthropods, and even carnivorous plants (Duellman and Trueb 1986. Biology of Amphibians. McGraw-Hill, New York; Pough et al. 1998. Herpetology. Prentice-Hall, New Jersey). Members of

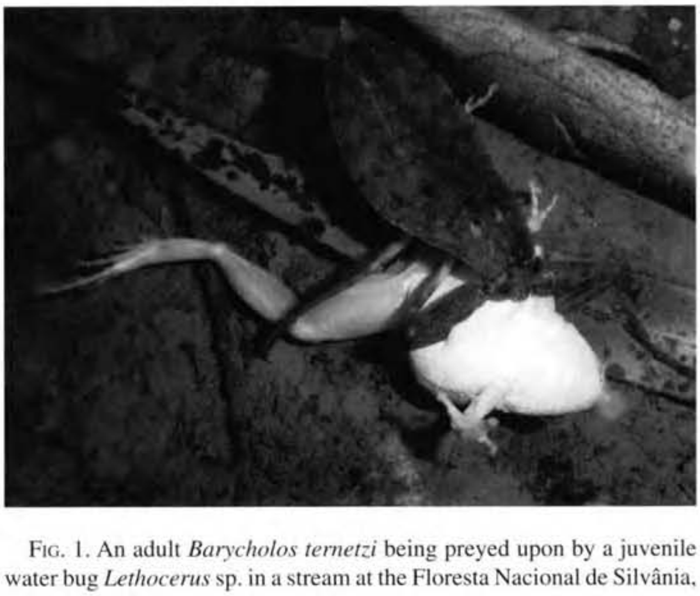

FIG. 1. An adult *Barycholos ternetzi* being preyed upon by a juvenile water bug *Lethocerus* sp. in a stream at the Floresta Nacional de Silvânia, State of Goiás, Brazil.

the family Belostomidae are predaceous aquatic insects from medium to large size, that colonize many types of aquatic habitats in tropical and temperate regions (Lauck and Menke 1961. Ann. Ent. Soc. Amer. 54:644–657). Here, we report the predation of an adult frog, *Barycholos ternetzi*, by a nymph of a water bug (*Lethocerus* sp.).

On 14 Oct 2005 at 2130 h, in a stream at the Floresta Nacional de Silvânia, State of Goiás, Brazil, a juvenile water bug was observed jumping toward an adult *B. ternetzi*. When the water bug was disturbed by our presence, it captured the frog and dove into the water to a depth of ca. 15 cm. Submerged in the water, the water bug remained grasping the frog from its ventral region (Fig. 1), which was trying to escape. A digital photograph was deposited with the Laboratory of Animal Behavior of the Universidade Federal de Goiás.

We thank Cynthia P. de A. Prado and Lorena D. Guimarães for comments on this manuscript.

BUFO NEBULIFER (Coastal Plains Toad). **URBAN ROAD MORTALITY**. Although motorways may affect wildlife populations investigators have performed few studies on the road mortality of wildlife (Lode 2000. J. Human Environ. 29:163–166), especially herpetofauna. The numbers of wildlife casualties on roads and railways have consistently grown as traffic, vehicle speeds, and their infrastructure networks have increased (Seiler et al. 2004. Wildl. Biol. 10:183–191). Amphibians and reptiles tend to be particularly susceptible to the ecological effects of roads (Forman and Alexander 1998. Ann. Rev. Ecol. Syst. 29:1–207). Road mortality along a 3.6 km section of a two-lane paved road adjacent to Big Creek National Wildlife Area on Lake Erie frequently included numerous amphibians (7 species, 30,034 individuals) and reptiles (10 species, 864 individuals; Ashley and Robinson 1996. Can. Field Nat. 110[3]:403–412). In most previous studies of road mortality, the roads crossed or were in some way associated with natural areas, thus providing significant data associated with large populations of amphibians and reptiles.

The Bowie Co., Texas study site was adjacent to Texas A&M University-Texarkana and Texarkana College on Virginia St. and Coolidge St. in Texarkana. Both paved, heavily trafficked, two-lane city-streets run parallel with, adjacent to, and approximately equidistant from Cow Horn Creek (a small stream that traverses Texarkana and receives much urban runoff). These streets differ in that Coolidge St. is lined by a subdivision on the side opposite Cow Horn Creek. Virginia St. is lined by a grassy field and the immediate area provides more habitat for wildlife. The roads were surveyed on foot for amphibian and reptile mortality on a 1.6 km stretch of Virginia St. on 1, 7, 14, 17, 20, and 28 June 2005. A 1.6 km stretch of Coolidge St. was surveyed on 17, 20, and 27 June 2005. Mean ambient temperature during surveys was 30.5°C (SD = 6.44). Data were tabulated and analyzed using MiniTab 13.30 Statistical Software (MiniTab, Inc., State College, Pennsylvania). This study is the first to examine *Bufo nebulifer* road mortality associated with movements to and from a breeding chorus.

Bufo nebulifer (N = 57) was the only species associated with road mortality in this study. Mortality data were normally distributed (Anderson-Darling: $A^2 = 0.604$, $P = 0.080$). Road mortality appeared higher on Virginia St. (N = 53, mean = 8.83 toads/survey, SE = 3.40) than on Coolidge St. (N = 4, mean = 1.33, SE = 1.33), but these differences were marginally significant (Two-sample T-test: $t = -2.05$, $df = 6$, $P = 0.086$; Neter et al. 1996. Applied Linear Statistical Models, 4th ed. McGraw-Hill. Boston, Massachusetts). The condition of specimens after mortality made sex determination difficult to impossible in most cases.

These data stimulate speculation regarding the influence of human habitation on habitat use by amphibians, particularly *B. nebulifer*. These data also suggest that *B. nebulifer* was originating from and returning to the grassy fields when mortality occurred. This implies that the breeding chorus in Cow Horn Creek was composed mostly of individuals originating from the grassy fields and that this habitat is important for the survival of this species in the immediate area. To deduce what influences undeveloped grassy fields and similar habitats occurring in urban environments have on sustaining urban populations of *B. nebulifer* and other herpetofauna will require more extensive studies.

BUFO WOODHOUSII (Woodhouse's Toad). **SURVIVAL.** Records that demonstrate maximal natural longevity are virtually nonexistent for anurans, or amphibians in general. Records from captive specimens have demonstrated longevities as high as 36 yr for *Bufo bufo* (Duellman and Trueb 1986. Biology of Amphibians. McGraw-Hill Book Co., New York. 670 pp.). Here, we describe the longevity of a wild *Bufo woodhousii* that was initially monitored in 1978 (Engeman and Engeman 1996. Northwest. Nat. 77:23; Engeman and Engeman 2003. Northwest. Nat. 84:45), including 9 yrs of records on its emergence from hibernation (Engeman and Engeman 1996. *op. cit.*). The toad first appeared as an adult in 1978 in a basement window well of a home in suburban Denver, Colorado. It was observed alive every year to 2003 when in July it was observed dead in the window well of undetermined cause. Given that the toad was an adult when first observed, and that it was observed alive in 26 successive years, implies the toad was at least 27 years old at the time of its death. This toad was not a captive specimen, but the window well site in which it lived probably offered protection from most potential predators and also probably provided reliable arthropod food sources and moisture, thereby imparting optimal circumstances for maximal longevity. We could not find reference to a greater longevity for a wild amphibian.

COPHIXALUS ORNATUS (Ornate Nursery Frog). **CHYTRIDIOMYCOSIS.** Chytridiomycosis is an emerging infectious disease that has been linked to amphibian population declines worldwide (Berger et al. 1998. Proc. Natl. Acad. Sci. 95:9031–9036). The chytrid fungus *Batrachochytrium dendrobatidis*, causative agent of chytridiomycosis, has an incredibly broad host range: it is currently known to infect over 150 amphibian species spanning two orders and 14 families (Speare and Berger 2004. www.jcu.edu.au/school/phtm/PHTM/frogs/chyglob.htm, updated with recently published accounts). Only seven of these species, however, are direct developers that bypass the free-swimming tadpole stage (*Eleutherodactylus cruentus, E. emcelae, E. melanostictus, E. karlschmidti, E. saltator, E. coqui, Leiopelma archeyi*). Tadpoles are thought to be an important life stage with respect to disease transmission: they stand a high chance of being exposed to the fungus' aquatic zoospores, and they do not succumb to chytrid infections, making them likely disease reservoirs (Daszak et al. 1999. Emerg. Inf. Dis. 5:735–748). Currently, there are no records of chytridiomycosis in Australian direct-developing frog species.

On 23 Sept 2005, KMK captured a male *Cophixalus ornatus* (Microhylidae) that was calling while perched on a leaf 2 m from the edge of Babinda Creek (70 m elev.), in Queensland, Australia. KMK firmly ran a cotton swab over the frog's dorsum, ventrum, sides, thighs, and the webbing of its feet, and used quantitative PCR (Boyle et al. 2004. Dis. Aquat. Org. 60:141–148) to test for the presence of *Batrachochytrium dendrobatidis*. Thirty-one chytrid zoospores were detected on the swab. This represents the first record of chytridiomycosis in an Australian direct-developing frog species, and only the eighth record worldwide.

There are no published reports of population declines in *C. ornatus*, a species whose large geographic range encompasses the localities of many of north Queensland's recent amphibian declines and disappearances, including that of *Taudactylus acutirostris* (the last known individual of which died of chytridiomycosis in 1995; Wright et al. 2001. J. Herpetol. Med. Surg.). Our finding of chytridiomycosis in *C. ornatus* supports the hypothesis that while all frog species might be exposed to the disease, there are ecological differences among sympatric species that might lead to different disease outcomes, ranging from no effect on the population to mass mortality events and local extinctions (Daszak et al. 1999, *op. cit.*; Hero et al. 2005 J. Zool. Lond. 267:221–232).

CRINIA SIGNIFERA (Eastern Froglet). **REPRODUCTION.** Multiple males simultaneously in amplexus with the same female is rarely reported in anurans. One of the species in which this behaviour is well documented is the quacking froglet *Crinia georginia* (Roberts et al. 1999. Anim. Behav. 57:721–726). Here I report multiple male amplexus for another member of the genus. *Crinia signifera* is the most widespread and abundant frog in eastern Australia. The observation reported here was made in wet subalpine flat heathland in the Thomsons Run area of the Mount Baw Baw Plateau on the 18 Nov 2003. Morning conditions had been clear and sunny, however by the time the amplexing frogs were found, conditions were cloudy and cool.

At ca. 1400 h a female *C. signifera* was observed on the surface of a pool in a sphagnum bog. Upon noting my presence, she attempted to dive into the detritus at the bottom of the pond. She could not dive successfully and upon closer examination two males were found to be clasping her. The first male was in inguinal amplexus, while the second male was clasping in a slightly lateral position with one arm around the hind leg of the female and other arm around the body of the first male. Both males were approximately the same size while the female was at least twice as large. The trio was observed for ten minutes after which they were disturbed and the second male released his hold and dove into the detritus. There were numerous eggs on the base of the pond where the female was first observed. I did not observe any further instances of multiple male amplexus in the remaining 13 days of fieldwork, although amplexing pairs were observed on three other occasions. Upon conversation with other workers it was mentioned that they had also observed instances of multiple males amplexing one female (Woodford, pers. comm.; Hollis, pers. comm.).

Multiple males in amplexus with a single female have not previously been reported in C. *signifera*. Two factors could potentially increase the likelihood of this behaviour occurring in high altitude populations. First this observation was made at peak breeding time for *C. signifera* on the Mt. Baw Baw Plateau. Four weeks earlier the area had been covered in snow, while several weeks later the number of frogs observed was clearly reduced. By mid December the ponds in the sphagnum bog had begun to dry up. This explosive breeding pattern may increase the potential for multiple males to be in the close proximity with single females. Secondly, the diurnal breeding behaviour of highland *C. signifera* may also increase the probability of males seeing females. Conversely, diurnal breeding may simply increase the potential for the behaviour to be noted by observers.

I thank Greg Hollis and Luke Woodford for their information, and P. Doughty for comments.

ELEUTHERODACTYLUS JOHNSTONEI (Johnstone's Whistling Frog). **HABITAT**. An increasing number of reptile and amphibian species have been documented to take advantage of the novel habitat provided by human night lighting (e.g., Perry and Lazell 2000. Herpetol. Rev. 31:247). Nonetheless, information is lacking for most species. Only one species of *Eleutherodactylus* is known to utilize the night-light niche (Henderson and Powell 2001. Carib. J. Sci. 37:41–54). *Eleutherodactylus johnstonei* is associated with humans in the Netherlands Antilles (Powell et al. 2005. The Reptiles and Amphibians of the Dutch Caribbean: St. Eustatius, Saba, and St. Maarten. St. Eustatius National Parks

Foundation, St. Eustatius, Netherlands Antilles), but has not previously been reported foraging at artificial lights.

At 2000 h on 5 Oct 2005, following several very rainy days, I observed a number of frogs arrayed around solar-powered trail lights on Saba, Netherlands Antilles. The observation was made at the Ecolodge Hotel (ca. 500 m elev.). Darkness had fallen ca. 1 h earlier, and a light rain was falling. Frog vocalizations were very loud, and many individuals were active on the vegetation. However, few frogs were occupying unlit lights, which were interspersed with the lit ones. A survey of all lights at the hotel identified 9 lit and 24 unlit trail lights, all solar. Despite being rather dim, the lights were attracting numerous small insects that were perched on or flitting about them. Lit units had 0–7 frogs on them (mean = 3.0, SD = 2.87). In contrast, unlit lights only had 0–3 frogs (mean = 0.3, SD = 0.76), a statistically significant difference (Mann-Whitney $U = 47.5$, $Z = 2.919$, $p = 0.004$). In addition, a brighter fluorescent light located at a height of about 2 m on the back of the hotel restaurant had ca. 30 frogs arrayed near it, an occurrence which hotel staff reported to be common.

Support for this project was provided by Texas Tech University, the Sea and Learn Program, and Ecolodge. This is manuscript T-9-1081 of the College of Agricultural Sciences and Natural Resource Management, Texas Tech University.

ELEUTHERODACTYLUS NITIDUS NITIDUS (Shiny Peeping Frog). **BODY TEMPERATURE**. The Mexican endemic, *Eleutherodactylus n. nitidus*, has been little studied. Dixon (1957. Master's Sci. Dissert., Grad. Sch. Agric. Mech. Coll. Texas, pp. 40–59) discussed distribution and geographical variation, and Lynch (1986. Herpetologica 42:248–258) discussed taxonomy. Woolrich-Piña et al. (2005. Anfibios y Reptiles del Valle de Zapotitlán Salinas, Puebla. UNAM-CONABIO, 54 pp. México) provide a more recent overview of natural history. On 13 July 2004, between 2200 and 0100 h we collected 10 *E. n. nitidus* on Cerro Chacatecas, Municipio Zapotitlán Salinas, Puebla, México. Cloacal temperature (T_C) was recorded using a quick-reading thermometer. We also recorded microhabitat temperature (air T_A, and substrate T_S) where the frogs were found. Mean T_C was $16.24 + 0.6$°C, mean T_A was $14.02 + 0.2$°C, and mean T_S was $14.8 + 0.3$°C. A positive and significant correlation was found between T_C and the temperature of the microhabitat ($T_C = -7.79 + 1.71\ T_A$, $r = 0.58$, $P = 0.008$, $N = 10$, for the air; $T_C = -9.24 + 1.72\ T_S$, $r = 0.807$, $P = <0.008$, $N = 10$, for the substrate).

Our results confirm a tendency toward thermoconformity in environmental and organismic temperatures as proposed by Huey and Slatkin (1976. Quart. Rev. Biol. 51[3]:363–384).

HYLA SQUIRELLA (Squirrel Treefrog). **REFUGIA.** Entomologists commonly use trap-nests to monitor cavity-nesting Hymenoptera. These trap-nests consist of 5 × 10 cm pine timber cut into 12-cm lengths. Five lengths are then stacked and strapped together. Each piece of timber is predrilled in each side to have either a 3.2, 4.8, 6.4, 7.9, or 12.7 mm diameter hole, 8 cm in depth. Thus, each trap-nest consisted of five pieces of wood containing 2 holes of each diameter. They are suspended with wire from tree trunks and branches. We set these wooden traps (N = 10) at Devil's Millhopper Geological State Park, Gainesville, Alachua Co., Florida, USA, from May 2003 to 25 Jan 2005. The habitat is a limestone sinkhole in mixed hardwood forest/pine flatwoods. On 25 Jan 2005, a juvenile *Hyla squirella* (SVL = 18.9 mm) had backed into an abandoned nest of a leafcutting bee, *Megachile xylocopoides* (Hymenoptera: Megachilidae), in a 12.7 mm diameter trap-nest. The abandoned nest which the frog inhabited was incomplete, consisting of 1–2 cells and was constructed from cut leaves lining the 12.7 mm diameter hole. The hylid died after capture; both the frog and the bee nest were deposited in the Herpetology Collection at the Florida Museum of Natural History (UF 143740). We observed other *H. squirella* (ca. 10 times) using trap-nests as refugia, perhaps hibernacula, at the same site during January and February of previous years. We removed all of these frogs from the traps and released them.

Hyla squirella are notorious for their nondiscriminatory habitat selection (Carr 1940. Univ. Florida Publ., Biol. Sci. Ser. 3[1]:1–118; Wright and Wright 1949. Handbook of Frogs and Toads of the United States and Canada. Third Ed. Cornell University Press, Ithaca, New York). Moreover, *H. squirella* typically are collected when they seek refuge in PVC pipe traps suspended from trees (Boughton et al. 2000. Am. Midl. Nat. 144:168–177; Bartareau 2004. Herpetol. Rev. 35:150–152; Muenz and Smith 2005. Herpetol. Rev. 36:75). This is the first instance of which we are aware of *H. squirella* utilizing the nests of megachilid bees as refugia, although we do not know if these hylids utilize naturally constructed megachilid nest cavities in woody vegetation. We recommend further investigation to determine the frequency, seasonality, and significance of this behavioral relationship with cavity nesting hymenoptera in natural situations.

These observations were made during a study of cavity-nesting hymenopterans in north-central Florida conducted by DS. This study was conducted under Permit 08170410 issued by the Florida Department of Environmental Protection.

LEPTODACTYLUS MARAMBAIAE (Marambaia White-lipped Frog). **DEATH FEIGNING.** Death feigning, or thanatosis, is a defense strategy widespread in anurans (Duellman and Trueb 1986. Biology of Amphibians. McGraw-Hill, Inc. 670 pp.). However, it has been rarely reported for the Neotropical family Leptodactylidae (Hartmann et al. 2003. Herpetol. Rev. 34:50; Toledo et al. 2005.

Herpetol. Bull. 91:29–31). Here we present the first report of death feigning in *Leptodactylus marambaiae*, a small leptodactylid (up to 40 mm SVL; Izecksohn 1976. Rev. Brasil. Biol. 36:527–530) endemic to the Restinga da Marambaia, in Rio de Janeiro State, southeastern Brazil (Frost 2004. Amphibian Species of the World: An Online Reference. Version 3.0, http://research.amnh.org/herpetology/amphibia/index.html). The Restinga da Marambaia is a thin strip of land, 42 km long, situated between Sepetiba Bay and the Atlantic Ocean, connected to the mainland by a narrow isthmus. It is covered predominantly by sandy soils and xerophytic vegetation (i.e. "restinga" habitat). Almost nothing is known about the biology and natural history of *L. marambaiae* (Izecksohn, *op. cit.*).

On 4 Oct 2005, at the western portion (2°04'07.4"S, 43°52'56.1"W) of the Restinga de Marambaia, three of us (CCS, RVM, and DV) found several individuals of *L. marambaiae* on the ground, among the grass, at night. At 2116 h, upon being picked up for observations, one individual (ca. 25 mm SVL) became immobile with limbs held close to the body, in typical death-feigning posture, even after being turned belly up. After being prodded with a finger by one observer, it stretched the front limbs a little, but continued immobile. It remained motionless for about two minutes, and was then released (whereupon it "came back to life" and jumped away). Death-feigning behavior similar to the one observed here have been reported for other anurans (Sazima 1974. J. Herpetol. 8:376–377; Zamprogno et al. 1998. Herpetol. Rev. 29:96–97; Vaz-Silva et al. 2004. Herpetol. Rev. 35:371; Toledo 2004. Herpetol. Rev. 35:371–372). To our knowledge, the only other species of *Leptodactylus* for which death feigning has been reported is *L. labyrinthicus* (Toledo et al., *op. cit.*) in the large-sized *L. pentadactylus* group. This note presents the second record of thanatosis in the genus *Leptodactylus*, and the first for a species in the small-sized *L. fuscus* group.

We thank the Força Aérea Brasileira for logistical support, and especially Captain Walter for allowing access to the area and making many facilities available. During this study CCS received a graduate grant from FAPERJ and RVM received a graduate grant from CNPq. MVS received a research grant from CNPq. Fieldwork was also supported by Conservation International/CEPF and the Instituto Biomas.

LEPTODACTYLUS NATALENSIS (Bubbling Frog) **PREDATION.** *Leptodactylus natalensis* occurs along the littoral of Brazil, extending from the northeast region to Rio de Janeiro (Heyer 1994. Smithson. Contrib. Zool. 546:1–124). During a study in a temporary pool at the Estação Ecológica do Tapacurá, a remnant of the Atlantic Forest located in the municipality of São Lourenço da Mata, in the state of Pernambuco (09°07'S; 34°60'W), we observed predation of *L. natalensis* eggs by the Scorpion Mud Turtle (*Kinosternon scorpioides*). *Leptodactylus natalensis* digs nest cavities along the edge of pools where the eggs are laid within a white foam and covered by foliage (dead vegetation) or herbaceous roots (Santos and Amorim 2005. Zoociências 7:39–45). On 18 May 2003 the presence of a nest at the east margin of the pool was recorded; it rained heavily in the region during the night and early morning of the next day and the area surrounding the nest was flooded. This caused the foliage-covered nest to float on the surface of the water (depth ca. 30 cm after the rain). During the afternoon of 19 May 2003, between 1439 and 1456 h (air temperature 26°C), a *K. scorpioides* was observed in the water feeding on the eggs dispersed among the foam for a period of 7 minutes. This is the first recorded instance of *L. natalensis* egg predation by *K. scorpioides.*

LITORIA JUNGGUY (Stoney Creek Frog). **PREDATION.** Reports of frog predation are biased towards those on tadpoles and juvenile frogs, and there are few reports on the predation of adult frogs, particularly of larger species. Here I report the apparent predation of a large adult *Litoria jungguy*, by a Long-finned Eel (*Anguilla reinhardtii*), during the course of a radio tracking study at a stream near Babinda, tropical north Queensland, Australia (145°55'S, 17°18'E, 20 m elev.). *Litoria jungguy* is a relatively large, terrestrial hylid frog, common in tropical north Queensland. During a radio tracking study, a female *L. jungguy* (SVL = 65.3 mm, mass = 26.8 g) was captured during the night of 17 March 2005 and fitted with a small (0.68 g) radio-transmitter attached to the frog externally with a silicon tubing waist-belt. During the study, frogs were located both diurnally and nocturnally for ca. two weeks. The last sighting of the frog was at 1930 h on 22 March 2005, when it was observed on terrestrial vegetation ca. 3 m from a stream. The following night at 2030 h, the transmitter signal was strongest under the submerged root mass of a tree in the same stream. For the next five days, I tracked the signal up and downstream along the river, which typically moved ca. 10 m between observations. The signal always originated from underwater and I was never able to observe any animal due to the signal coming from undercut banks, root masses, and dense terrestrial vegetation. On the 28 March 2005 at 1200 h I recovered the transmitter, still attached to the tied waistband. As it would have been impossible for the waistband to remain tied and fall off the frog, due to the small waist-size and robust thighs of the frog, the frog must have been eaten by a large, aquatic predator. *Anguilla reinhardtii* was the only such predator present in the study stream, was commonly encountered, and published behavior and habitat preferences for the species match those observed in my study (Pusey et al. 2004. Freshwater Fishes of North-eastern Australia. CSIRO Publishing, Collingwood). I therefore conclude that the *L. jungguy* was predated upon by an *A. reinhardtii*.

Submitted by **JODI ROWLEY**, School of Tropical Biology, James Cook University, Townsville, Queensland 4811, Australia.

MANTIDACTYLUS LIBER (NCN) and ***M. DEPRESSICEPS*** (NCN). **CROSS-SPECIES MATING.** Among the Malagasy herpetofauna, mantellines are one of the major clades of frogs, and are characterized by several features related to reproduction and mating behavior (Blommers-Schlösser 1979. Beaufortia 29:1–77). To date all known *Mantidactylus* and *Mantella* males lack strong mating amplexus, nuptial pads, and release calls (Glaw and Vences 1994. A Field Guide to the Amphibians and Reptiles of Madagascar. 2nd edition. Vences and Glaw, Köln. 480 pp.). The femoral glands of these frogs have been suggested as a possible organ to stimulate the female during the fertilization of the eggs (Glaw and Vences 1994, *op. cit*), or to aid in attachment to female during reproduction (Brizzi et al. 2003. *In* B. G. M. Jamieson [ed.], Reproductive Biology and Phylogeny of Anura. Science Publ., New Hampsire. 452 pp.), but these hypotheses have not been tested.

Reproductive behavior has been best studied in species such as *Mantidactylus liber* and *M. depressiceps* (Blommers-Schlösser 1975. Beaufortia 23:15–25) that belong to the subgenus *Guibemantis* in the genus *Mantidactylus*. They deposit eggs on leaves overhanging stagnant waters where tadpoles later complete their development. Females and males, which are of similar body size, sit on vertical leaves, the males at higher positions, with their posterior body and hind limbs covering the female's head and anterior dorsum. The sperm of male probably slides down the back of the female reaching the eggs laid by the female (Blommers-Schlösser 1975, *op. cit.*; 1979, *op. cit.*). There have been no records of mixed mating or hybridization among these species.

FIG. 1. Male *Mantidactylus liber* (small specimen, top) mating with a female *M. depressiceps* (bottom) that already has deposited its (white) eggs. Photographed at Ranomafana National Park, 21 Jan 2004.

On 21 Jan. 2004, before sunset (ca. 1700 h), we observed a large breeding aggregation of *M. depressiceps*, *M. liber*, and *M. tornieri* in a roadside ditch along the road between Vohiparara and Ranomafana (21°15.387' S, 47°24.602' E, 1013 m elev., Ranomafana National Park). Explosively timed intense breeding was observed during three consecutive days whereas subsequently only single individuals were found. During several instances we observed male-male combat in *M. depressiceps*, and an instance in which a sneaking male interrupted a mating pair.

In one case a male *M. liber* attempted to mate with a female *M. depressiceps* that had just deposited her clutch of typical white eggs (Fig. 1). Females of these species are known to guard eggs for minutes or hours after their deposition. *Mantidactylus liber* is a distinctly smaller species than *M. depressiceps*, yet the male performed rhythmical reproductive movements with its hind limbs over the female's head as typical (Blommers-Schlösser 1975, *op. cit.*). This behavior was continuous for at least 10 min before the individuals separated, probably disturbed by the heavy rain and our photography. These observations demonstrate that cross-species mating is possible in sympatric explosive breeding *Mantidactylus*, despite their different advertisement calls and body size, and lack of amplexus behavior.

PHYLLOMEDUSA BURMEISTERI (Leaf Frog). **BEHAVIOR.** In many anurans, territorial behavior is common during male-male interactions (Martins et al. 1998. Amphibia-Reptilia 9:46–90). It is accomplished through behavioral patterns ranging from calls (advertisement, territorial, and/or encounter calls) to physical combat (Halliday and Tajedo 1995. *In* Heatwole and Sullivan [eds.], Amphibian Biology, Volume 2: Social Behaviour, pp. 419–468. Surrey Beatty & Sons). The data available for aggressive behavior in *Phyllomedusa* show that breeding aggregations of this species are characterized by low number of individuals, site fidelity, complex vocal repertoire, visual communication, and male-male combat, suggesting that calling males exhibit territorial behavior (Abrunhosa and Wogel 2004. Amphibia-Reptilia 25:125–135).

Herein, we report attempted dislodgment of an amplectant male *P. burmeisteri* by two solitary males. The observation were made in gallery forest vegetation over a stream near the Mucuri River (17°44'S, 41°43'W), municipality of Poté, State of Minas Gerais,

FIG. 1. Aggressive behavior (i.e., fighting) in *Phyllomedusa burmeisteri*, depicting three males in direct contact with the female, while a fourth male waits nearby.

Brazil, on 1 Dec 2004. The observation started when the pair was already in amplexus, ca. 2.5 m above ground, and three solitary males were perched on nearby bushes, emitting advertisement calls. The dislodgment attempt started when one of the solitary males approached the pair, trying to grasp the female from the ventral surface. During this confrontation, the amplectant male physically contacted the intruder male, stretching and retracting his legs (alternating the legs), trying to remove the intruder from the female and himself. This behavior of the amplectant male was similar to that reported by Abrunhosa and Wogel (2004, *op. cit.*) during acoustic interactions between calling males. The intruder, in turn, seized the head of the amplectant male while still holding the female's ventral surface. At this moment, the female was suspended from a leaf by her feet, still being held by the two males. The second solitary male joined the group, but stayed in a position opposite of the female and the other two males, with his head directed toward top. The female remained suspended from the leaf with her feet, while the three males grasped her, emitting encounter calls and using their nuptial excrescences to attack the opponents. A third solitary male was perched nearby and was not directly involved in the dislodgment attempt (Fig. 1). After ca. 40 min the female fell on the vegetation and only the first male remained in amplexus. The latter phases of courtship (oviposition) were not observed.

We thank P. Abrunhosa and J. P. Pombal Jr. for commenting on the manuscript, P. Barrancos for the local facilities, and ProBio/MMA, Conservation International, and CNPq for providing financial support.

PHYLLOMEDUSA TRINITATIS (Trinidad Leaf Frog). **HABITAT USE**. *Phyllomedusa trinitatis* is generally considered to be a widespread, lowland species that occurs in secondary forests and along forest edges (Murphy 1997. Amphibians and Reptiles of Trinidad and Tobago. Krieger Publishing Co., Malabar, Florida. 245 pp.). In Trinidad, this frog has rarely been observed at elevations exceeding 100 m (Kenny 1969. Studies of the Fauna of Curacao and Other Caribbean Islands 29(108):1–78). Here, we report an observation of *P. trinitatis* in montane rainforest during the wet season.

On 24 July 2005 at 1745 h EST, we captured an adult female *P. trinitatis* at our camp on Morne Bleu Ridge in the Northern Range of Trinidad (10°43'53"N, 61°15'08"W; WGS 84; elev. 823 m). Local vegetation at this site is typical for montane rainforest and features several species of palms, bromeliads, lianas, and small trees with a closed canopy between 15–18 m. The frog (80 mm SVL) was caught shortly before dusk, observed briefly, photographed, and released. At the time of the observation, there was virtually no precipitation. However, for the preceding 24 h (especially from 1800 h on 23 July to 1500 h of 24 July), our camp had been inundated with a steady and, at times, heavy rainfall (ca. 2 cm/h).

Murphy (1997, *op. cit.*) noted the occurrence of seven anuran species in the montane rainforests in Trinidad, including two bromeliad-breeding specialists (*Flectonotus fitzgeraldi* and *Phyllodytes auratus*, an endemic) and five widespread, habitat generalists (*Bufo marinus*, *Mannophryne trinitatis*, *Phrynohyas venulosa*, *Eleutherodactylus urichi*, and *Leptodactylus validus*). Our observation increases this total and indicates that *P. trinitatus* might more extensively use montane rainforests than previously believed.

RANA CATESBEIANA (American Bullfrog). **DIET**. Bullfrogs are opportunists capable of capturing a wide variety of prey, including flying insects, bats, and birds (Bury and Whelan 1984. US Fish Wildl. Serv. Publ. 155. USDI, Washington, DC). Here I present evidence of an additional bird species caught as prey: Anna's Hummingbird (*Colypte anna*).

On 20 Aug 2003, at Valentine Pond in Joseph Grant County Park in Santa Clara Co., California, USA (37°19'14.043"N, 121°40'22.226"W), I captured an adult female *R. catesbeiana* (178 mm SUL, 595 g, gape 64 mm). After a photograph was taken, the frog was killed and stored in a cooler until the end of the workday.

That evening I weighed and measured the frog, removed the entire digestive tract, and froze it for later processing. Months later, I thawed the sample and opened the stomach to discover it contained a darkling beetle (*Eleodes dentipes*), a Pacific Treefrog (*Hyla regilla*), and the feathers and partially digested bones of a hummingbird. The tail feathers were intact, but bones of the posterior skeleton disintegrated at the slightest touch. I opened the rest of the digestive tract and discovered the remaining feathers and the ramphotheca of an Anna's Hummingbird. The presence of the reddish gorgette feathers confirmed the hummingbird bird was a male, and that the bird had been swallowed headfirst.

I thank D. Clark of the Santa Clara County Parks Department for his facilitation and help with the survey.

RANA CATESBEIANA (American Bullfrog). **MORTALITY**. *Rana catesbeiana* is an ambush predator with a highly varied diet (Bury and Whelan 1984. U.S. Fish Wildl. Serv. Res. Publ. [155]:1–23). Snakes, including garter snakes (*Thamnophis* spp.; McKamie and Heidt 1974. Southwest. Nat. 19:107–111; Bury and Whelan, *op. cit.*), are occasionally taken, but the Northwestern Garter Snake (*Thamnophis ordinoides*) has not been reported as prey, despite the fact that the introduced range of *R. catesbeiana* broadly overlaps that of *T. ordinoides* in the Pacific Northwest (Nussbaum et al. 1983. Amphibians and Reptiles of the Pacific Northwest. Univ. Press of Idaho, Moscow. 332 pp.; Leonard et al. 1993. Amphibians of Washington and Oregon. Seattle Audubon Society, Seattle. 168 pp.; Dvornich et al. 1999. Washington State Gap Analysis. http://wdfw.wa.gov/wlm/gap/dataprod.htm). Moreover, reports of mortality resulting from consumption of prey are rare for ranid frogs, despite their generally voracious feeding habits. Hence, we here provide an unusual observation of *R. catesbeiana* predation on *T. ordinoides*, an event that apparently resulted in the death of the former.

At 1700 h on 10 April 2005, we encountered a dead adult (121 mm SVL) female *R. catesbeiana* on the muddy bank of a farm pond in Marion County, Oregon (45°13'56"N, 122°47'22"E, WGS 84; elev. 55 m). We found the frog 1.5 m up the bank, its limbs outstretched in a crawling position. Closer examination revealed that the frog had the tail of a snake protruding from its cloaca. The frog had lost at least 25% of its body volume to desiccation. Its ventral surface, particularly the undersides of its legs and feet, was reddish in color, as opposed to the white or cream color of a healthy American Bullfrog.

Dissection of the frog revealed the protruding tail was *T. ordinoides* (> 400 mm SVL) of unknown sex (combined mass of frog and snake = 127 g). The anterior portion of the snake, in the frog's esophagus, was partly digested. In particular, the skin and muscle tissue on the snake's head (located in the lower esophagus) was digested enough to reveal the bones of the skull. Curiously, the portion of the snake in the frog's stomach (a ca. 100 mm long segment) appeared undigested, with skin and scales still intact. Progressing posteriorly, the segment of the snake passing through the frog's intestine (a piece > 100 mm long) was increasingly digested. The last 106 mm of the snake protruded from the

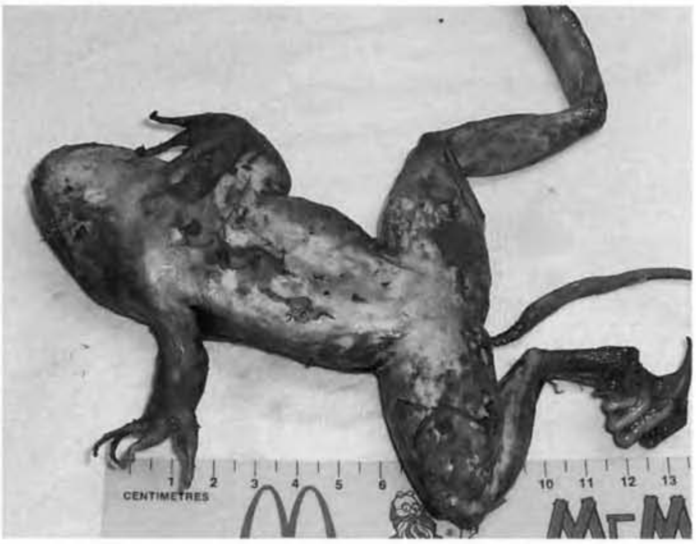

FIG. 1. Dead *Rana catesbeiana* (121 mm SVL) with tail of *Thamnophis ordinoides* protruding from vent.

frog's cloaca. Of this last part, the 10 mm closest to the frog's body had been reduced to spine; the remaining 96 mm of tail were completely intact, with no noticeable digestion of the skin, scales, or muscle tissue.

The frog's internal organs were found in varying states of necrosis. In best shape were the lungs, heart, and upper digestive tract (esophagus and stomach); the lungs appeared least decomposed of all and were still red. The lower portions of the intestine were the most decomposed; in particular, a section of the large intestine between 1.5 and 5.5 cm anterior to the frog's cloaca was black and entirely necrotic. The snake's scales had perforated this section of intestine, presumably as the snake passed through tail-first. The intestine at this point was impacted, and several centimeters of the intestine were "bunched up" around the tail of the snake. The advanced decomposition of the length of snake extending from this point to the cloaca suggested that this portion of the snake had been fixed in place for a relatively long time.

We hypothesize that the events leading to the frog's death were as follows: The frog ate the snake, swallowing it tail first. As the diameter of the snake's body passing through the frog's intestine increased, the backward-pointing, keeled scales caught on the frog's intestinal wall, causing impaction and subsequent perforation of the intestine. As a result of this perforation, bacteria from the fecal material and putrefying snake initiated a localized infection that quickly became systemic, killing the frog.

Two points of this observation are noteworthy. First, the identity of the prey reveals that the introduced *R. catesbeiana* preys on *T. ordinoides*, an observation for which this represents the first published record. Second, this observation illustrates a risk associated with eating rough-bodied prey (e.g., snakes with keeled scales), even if the defensive capabilities of the prey species are ineffective in preventing their consumption.

RANA DRAYTONII (California Red-legged Frog). **PREY.** Few dietary data exist for *Rana draytonii*, a taxon only recently recognized as a full species (Shaffer et al. 2004. Mol. Ecol. 13:2667–2677). Available data are those of Hayes and Tennant (1985. Southwest. Nat. 30:601–605), who reported on the gastrointestinal tract contents of 35 post-metamorphic frogs collected in Los Angeles, San Bernardino, and Santa Barbara counties, California, USA. Moreover, its federal status as a threatened species since 1996 (US Fish and Wildlife Service 1996. Fed. Regist. 61:25813–25833) has limited the ease of gathering additional dietary data. Hayes and Tennant (*op. cit.*) reported a single adult *Peromyscus californicus* in two female *R. draytonii* (117 and 128 mm SVL; MPH, unpubl. data). To these data, we add two additional observations.

Henry Carsten Kellers collected a 126 mm SVL adult female *R. draytonii* (United States National Museum of Natural History [USNM] 52899) at Calistoga (38°34'N, 122°34'W WGS 84; elev. 110 m), Napa Co., California. The collection date is unknown, but the accession date is 27 Sept 1915. The location is imprecise, but springs and marshes were extensive in the vicinity of Calistoga at the time of collection (Archuleta 1977. The Brannan Saga, Early Day Calistoga. Smith-McKay Printing, San Jose, California. 116 pp.). The stomach of this frog contained a *Microtus californicus*, which was nearly adult-sized based on the 20.1 mm length of its left hind foot (Jameson and Peeters 2004. California Mammals. Revised ed. Univ. California Press, Berkeley. 440 pp.).

On 2 May 1996, GBR collected a dead and desiccated adult female *R. draytonii* (USNM 539491) in altered coastal scrub habitat in a fenced compound with several sewage percolation ponds (see Rathbun et al. 1997. Herpetol. Rev. 28:85 for details) operated by the Cambria Community Services District, ca. 6 km NW of Cambria (35°35'48"N, 121°07'08"W, WGS 84; elev. 5 m), San Luis Obispo Co., California. This frog, whose size and mass were recorded as 119 mm SVL and 167 g on 18 March 1996 (Rathbun et al., *op. cit.*), had an adult *Reithrodontomys megalotis* (USNM 568171) in its stomach.

Two aspects of these observations merit comment. *Rana draytonii* makes significant seasonal forays into terrestrial habitat (Rathbun et al., *op. cit.*; Bulger et al. 2003. Biol. Conserv. 110:85–95), so opportunities for largely nocturnally foraging adults to encounter small mammal prey may be frequent. Both of these small mammal species often occur at high densities in mesic terrestrial habitats near aquatic habitats in coastal California (Blaustein 1980. Behav. Ecol. Sociobiol. 6:247–255). Second, as with the previously published observations of small mammal prey (Hayes and Tennant, *op. cit.*), these observations involve adult female frogs. Females average ca. 20 mm SVL larger than males (Hayes and Miyamoto 1984. Copeia 1984:1018–1022), so females may consistently take larger prey than males.

Steve Gotte, Roy McDiarmid, and Robert Fisher (USGS Patuxent Wildlife Research Center), and Jeremy Jacobs (Smithsonian Institution) assisted in the examination the *R. draytonii* specimens, identification of the mammal prey, and provision of measurements. GBR's 1996 work was conducted under federal subpermit NBSPBS-1.

RANA SYLVATICA (Wood Frog). **TERRESTRIAL AMPLEXING PAIRS**. On the evening of the 17 April 2005, at ca. 2100 h, three amplexing pairs of *Rana sylvatica* were found on Crowe's Line Road near Bobcaygeon, Ontario, Canada (44°33'N, 78°33'W). The pairs were likely heading toward a large chorus of 200–300 male *R. sylvatica* (as well as two other chorusing species) in the wetland on the other side of the road (the direction in which the female of each pair was oriented). Upon further investigation of the wetland, ca. 25–30 freshly deposited *R. sylvatica* egg masses were found. The air temperature was 10–12°C, and the water temperature in the wetland was 12°C. The sky was clear and three quarters of the moon was visible; the humidity was low; the road was not moist nor were the ditches particularly wet.

The discovery of terrestrial amplexing pairs suggests that male *R. sylvatica* might have an alternate mating strategy to attending and participating in a chorus, that is, intercepting and amplexing a female on land and then being piggy-backed by the female to a suitable oviposition site.

These specimens are currently reposed at Trent University, Peterborough, Ontario and are part of an ongoing study of emerging wildlife diseases in Ontario. We thank Michael Berrill and Jean Duffus for comments on earlier versions of this note.

IRELAND,** Haliburton Forest and Wildlife Reserve Ltd., Haliburton, Ontario, KOM 1SO, Canada (e-mail: ireland_hfwr@yahoo.ca).

RANA SYLVATICA (Wood Frog). **TADPOLE MAXIMUM SIZE.** On 24 July 2004, eight *Rana sylvatica* tadpoles were collected at Pointe-des-Monts, Québec, Canada (49°19'8"N, 67°24'30"W), on the north shore of the St.-Lawrence River. These tadpoles, up to 66 mm TL, are the largest reported for the species. Maximum TL reported in the literature is 48 mm (Conant and Collins 1998. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. 3rd ed. Houghton Mifflin Co., Boston, Massachusetts. 616 pp.), 49 mm (Wright and Wright 1949. Handbook of Frogs and Toads of the United States and Canada. Comstock Publ. Assoc., Ithaca, New York. 640 pp.), and 50 mm (Orton 1952. Amer. Midl. Nat. 47:382–395). Our tadpoles are up to 16 mm longer TL. About 15 tadpoles were seen in this pool; eight were collected and deposited at the Canadian Museum of Nature (CMNAR 35819). Total lengths are 66.3, 65.8, 65.7, 65.0, 63.7, 62.3, 61.4, and 56.22 mm, the last having a broken caudal fin. Body lengths (tip of snout to base of hind limbs) range from 20.8 to 22.3 mm. All have hind limbs and are at Gosner Stages

38–39 (Gosner 1960. Herpetologica 16:183–190).

Tooth row formula for most of these tadpoles is 3/4 (3 upper rows and 4 lower). Two tadpoles have 3/3 tooth rows, but one seems to have partially broken mouthparts.

These tadpoles were in a 6 × 7 m pool in bedrock, 30 cm deep, located 60 m from the St.-Lawrence River. It was bordered with Black Crowberry (*Empetrum nigrum*) and Leatherleaf (*Chamaedaphne calyculata*). The water was salty, with a marine fauna: Blue Mussel (*Mytilus edulis*), Steamer Clam (*Mya arenaria*), Periwinkle (*Littorina* sp.), Sandworm (*Nereis virens*), and barnacle (*Balanus* sp.). Coniferous forest was about 100 m N of the pool.

The major interest in this discovery is to understand why these northern shore line Wood Frog tadpoles are so big: has their growth been enhanced or their metamorphosis inhibited? It seems likely that the pool would have frozen solid during the winter, so they might have grown to this exceptional size in the two months since the breeding season.

RANA SYLVATICA (Wood Frog). **CHYTRIDIOMYCOSIS.** The chytrid fungus, *Batrachochytrium dendrobatidis* (BD), has been implicated in mass amphibian mortalities and global population declines (Berger et al. 1998. Proc. Natl. Acad. Sci. 95:9031–9036; Pounds et al. 2006. Nature 439:161–167). On 25 July 2002, a dead subadult male *Rana sylvatica* (26 mm SVL; 1.8 g body weight after ethanol fixation) was collected near a pond on the Kenai National Wildlife Refuge, Alaska, USA (60.62741°N, 150.81557°W, WGS 84). The frog was preserved in ethanol and shipped to the U.S. Geological Survey, National Wildlife Health Center (NWHC) in Madison, Wisconsin, USA. A whole-body radiograph of the specimen showed a normal musculoskeletal system with a paucity of calcium carbonate in the paravertebral endolymphatic sacs. Histological sections of two hindlimb digits and ventral skin (pelvic patch area) showed mild hyperkeratosis of the epidermis with numerous 6–12 μ diameter empty chytrid thalli within keratinized cells of the *stratum corneum*. These epidermal lesions were diagnosed as mycotic hyperkeratotic epidermitis due to infection by BD. On 18 July 2002, five dead tadpoles were observed at this site but not submitted for disease diagnosis. Calling adult Wood Frogs, egg masses, or tadpoles were detected in 18 of 26 site visits during 2000–2005, and live frogs were documented at the site each year. This site borders a gravel road. There are no reptiles or fish at this site. No other species of amphibian has been detected on the Kenai Refuge during surveys of >100 ponds during 2000–2005. Waders and nets are disinfected with 5% bleach solution between sites. This is the first report of a BD-infected frog from Alaska. The effects of BD at such a high northern latitude, and on this population, are unknown. The specimen is stored in ethanol at the National Wildlife Health Center (Case #4848-041).

RANA YAVAPAIENSIS (Lowland Leopard Frog). **EGG AND TADPOLE PREDATION.** Ranid frogs in the western United States have been disproportionally affected by amphibian declines (Bradford 2005. *In* M. Lannoo [ed.], Amphibian Declines: The Conservation Status of United States Species, pp. 916–925. Univ. California Press, Berkeley). Among the many causative agents for these declines, predation by non-native fishes has been strongly implicated, especially in naturally fish depauperate areas (Bradford 2005, *op. cit.*). However, first-hand descriptions of egg predation by introduced fish have rarely been reported. Here, I describe predation on a *Rana yavapaiensis* egg mass by non-native catfish in southern Arizona.

On 20 August 2002, I watched two *Ameiurus melas* (Black Bullhead; Deborah Sebesta, USFS District Biologist, Coronado National Forest, pers. comm.), each ca. 25–35 cm long, prey upon a *R. yavapaiensis* egg mass. The egg mass was located within 5–10 cm of the water's surface, ca. 2.5 m from the creek shore, in water 1.0–1.5 m deep, in a slow moving oxbow of Peck Canyon in southern Arizona (31°29'N, 111°04'W). The substrate was coarse sand and gravel. The eggs were just hatching, Gosner Stages 20–25 (Gosner 1960. Herpetologica 16:183–190), and the hatchling tadpoles were still in a tight aggregation around or within the egg mass. The fish repeatedly swam through the egg mass with mouths open, turning around for another run after passing beyond the eggs by 10–30 cm. The possibility exists that the eggs were of *R. chiricahuensis*, also recorded from the general area. However, on this day hundreds of *R. yavapaiensis* metamorphs were observed, with no *R. chiricahuensis* documented from this length of the canyon (unpubl. data).

I thank Kevin Bonine and Cecil Schwalbe for reviewing an earlier version of this note.

RHACOPHORUS KAJAU (White-eared Tree Frog). **FOOT FLAGGING.** A population of *Rhacophorus kajau* occurs at Kubah National Park (01°33'N, 110°12'E), Matang, Sarawak, Malaysia (Borneo). While being photographed *ex-situ* indoors on 11 Dec 2005 and 22 Jan 2006, two adult males exhibited a behavior previously unreported in this species. While keeping the forelimbs planted on the substratum (in both cases, green leaves), the hind limbs were extended upward, and turned counter-clockwise at the level of the knee, with the undersurfaces of the shanks and sole touching the posterior of the dorsum of the body (Fig. 1). The entire action was performed in under 1 sec. Males of *R. kajau* are typically found in social groups of up to five in the wild. We suggest that the behavior, exhibited under stress such as handling associated with photography or the bright light from a flash, simulates the behavior, and is a warning to conspecifics, when the pale undersurfaces of limbs, black webbing, and/or the typically con-

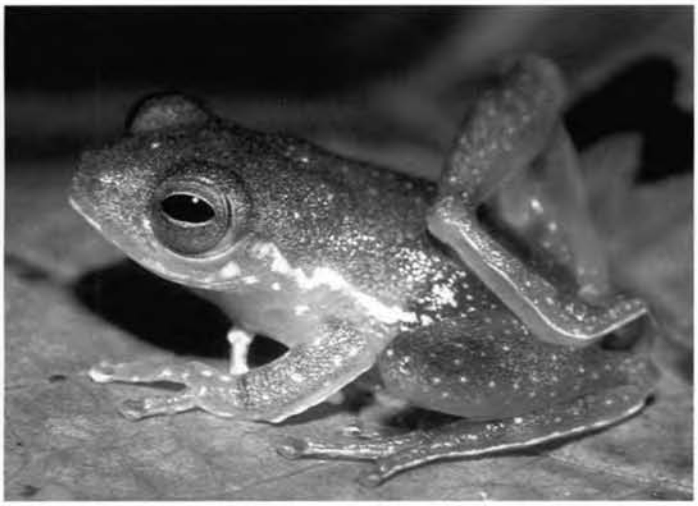

FIG. 1. Foot-flagging in *Rhacophorus kajau*, showing a hind limb turned counter-clockwise at the level of the knee.

cealed orange-colored trailing edges of the thighs are briefly exposed. Other examples of foot flagging reported in anuran amphibians (e.g., Hödl and Amézquita 2001. *In* M. J. Ryan [ed.], Anuran Communication, pp. 121–141. Smithsonian Institution Press, Washington, D.C. and London; Malhotra and Davis 1991. J. Bombay Nat. Hist. Soc. 88:157–166; Davison 1984. Sarawak Mus. J. 33:177–178) are associated with reproduction.

We thank the Sarawak Forestry Corporation for permission to work in areas under its jurisdiction; the Institute of Biodiversity and Environmental Conservation, Universiti Malaysia Sarawak, and Biozentrum Grindel und Zoologisches Museum, Universität Hamburg for support; and Volkswagen Stiftung for a research grant (No. 1/79 405).

SCINAX ALCATRAZ (Alcatraz Snouted Treefrog). **PREDATION.** *Scinax alcatraz* is endemic to Ilha dos Alcatrazes and listed as critically threatened by IUCN (2004. Guidelines for protected area management categories). The natural history of this species has not been studied in detail. Here we describe the first report of *S. alcatraz* predation by a spider. The observations were made at Ilha dos Alcatrazes, an island of 135 ha located 35 km off the coast of São Paulo State, Brazil (24°06'S, 45°42'W). On 22 Nov 2005 at 2230 h, we observed an immature Wandering Spider (*Oligoctenus medius*; Ctenidae) preying on an adult male *S. alcatraz* (23.8 mm SVL) on a bromeliad leaf. At the moment of the observation, the spider was biting the middle section of the treefrog's thigh (Fig.1). The frog was alive but motionless with legs extended. We captured the prey and predator separately. In a few hours, the treefrog was dead. Our observation corroborates studies suggesting that spiders may be important predators of frogs (Hayes 1983. Biotropica 15[1]:74–76). The specimen of *S. alcatraz* is deposited at Coleção de Anfíbios, Departamento de Zoologia, UNESP – Campus Rio Claro, Brazil (accession number CFBH 10463). The specimen of *O. medius* is deposited at Coleção de Aranhas, Instituto Butantan, São Paulo, Brazil (accession number IBSP 59750).

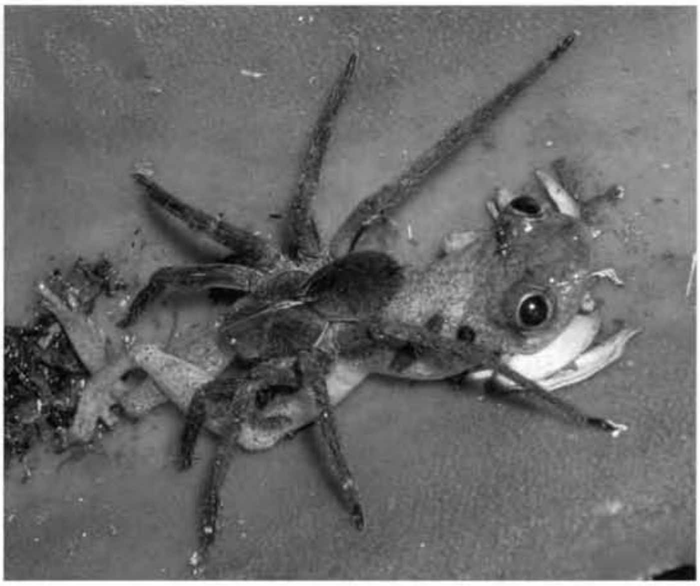

FIG. 1. Adult male *Scinax alcatraz* being captured and envenomated by an immature Wandering Spider on Ilha dos Alcatrazes, Brazil.

We are grateful to K.R. Zamudio for comments on this manuscript. We thank Estação Ecológica de Tupinambás, Instituto de Biologia da Conservação, Fapesp, Biodiversitas/CEPAN, Fundação O Boticário and Idea Wild for logistical and financial support; Dr. Rogerio Bertani identified the spider. CAB was funded by Fapesp and HMO by CNPq during this project. Specimens were collected under permit number 184/2004 issued by IBAMA.

THOROPA MILIARIS (Rock River Frog). **TADPOLE PREDATION**. Anurans are preyed upon by several types of invertebrates (Hinshaw and Sullivan 1990. J. Herpetol. 24:196–197; Marra et al. 2003. Herpetol. Rev. 34:55–56; Peltzer and Lajmanovich 2003. Herpetol. Rev. 34:231; Tsuji 2005. Herpetol. Rev. 36:125–127). Information is available on insects as predators of both adult (Haddad and Bastos 1997. Amphibia-Reptilia 18:295–298; Brasileiro et al. 2003. Herpetol. Rev. 34:137; Toledo 2003. Phyllomedusa 2:105–108) and tadpole (Azevedo-Ramos et al. 1992. J. Herpetol. 26:335–338; Hero et al. 1998. Austr. J. Ecol. 23:474–482; Azevedo-Ramos and Magnusson 1999. Copeia 1999:58–67; Eterovick and Sazima 2000. Amphibia-Reptilia 21:439–461) anurans in Brazil. The nocturnal frog *Thoropa miliaris* is a leptodactylid endemic to the Brazilian Atlantic Rainforest

Biome that lives on and among wet rocks in all stages of its life cycle (Bokermann 1965. An. Acad. Bras. Ci. 37:525–537). Here, we report an incidence of predation on a *T. miliaris* tadpole by an insect larva.

At 2328 h on 24 Sept 2005 at the Mãe D'Água dam (23°10'92.3"S, 44°12'04.4"W) in Ilha Grande, an island located in the southern coast of Rio de Janeiro State, municipality of Angra dos Reis, southeastern Brazil, two of us (CCS and CVA) observed a larval *Tropisternus* sp. (Coleoptera, Hydrophilidae, total length 10.8 mm) attacking a tadpole *T. miliaris* (body length 8.0 mm, total length 25.0 mm) in a small stream in the forest. Larval *Tropisternus* cannot be identified to specific level. The larva was moving along the water film on a rock when it captured the tadpole, grabbing it by the tail base, and entered the tadpole's body through the vent tube. The insect took about two minutes to kill the tadpole and then started eating it from the inside, which it did for around 12 minutes. Then it broke part of the tadpole's tail and started squeezing it and consuming the flesh at the broken end of the tail, for about nine minutes. It then stopped eating, but after seven minutes it restarted. At 0014 h it stopped again. The observation lasted about one hour. During this period, another larval *Tropisternus* sp. attempted to capture two other tadpoles but was unsuccessful. The larva was collected and deposited at the Coleção Entomológica do Departamento de Zoologia da Universidade Federal do Rio de Janeiro (DZRJ-1975).

Previously reported predators of eggs and tadpoles of *Thoropa miliaris* are conspecific tadpoles (Giaretta and Facure 2004. Biota Neotropica 4:1–10) and adult *Cyclorhamphus boraceiensis* (Hartmann et al. 2003. Herpetol. Rev. 34:50). Dipteran larvae (maggots) have been reported as predators of eggs of *Thoropa lutzi* (Bokermann, *op. cit.*). This is the first report of predation by an insect on *T. miliaris* tadpoles.

We thank Davor Vrcibradic for helpful suggestions on the manuscript, and Janira Martins Costa and Nelson Ferreira Junior for identifying the insect larva. We thank the Centro de Estudos Ambientais e Desenvolvimento Sustentável (CEADS/UERJ) for local support and for making many facilities available. During this study CCS received a graduate fellowship from FAPERJ, and CFDR (Processes No. 307 653/2003-0 and 477981/2003-8) and MVS (Process No.301401/04-7) received Research Grants of the Conselho Nacional de Desenvolvimento Científico e Tecnológico – CNPq.

XENOPUS LAEVIS (African Clawed Frog). **SURFACE PREY CAPTURE**. The aquatic *Xenopus laevis* is regarded as predominantly feeding on aquatic invertebrates (Inger and Marx 1961. Explor. Parc. Natn. Upemba 64:1–85; Kazadi et al. 1986. Ann. Soc. R. Zool. Belg. 116:227–234; Schoonbee et al. 1992. Wat. S. Afr. 18:227–236). However, some field studies also report a large number of terrestrial invertebrates in the stomach contents of *Xenopus*. Tinsley et al. (1996. *In* Tinsley and Kobel [eds.], The Biology of *Xenopus*, pp. 35–59) suggested that *Xenopus* might capture prey from the water surface, but "this possibility has been inadequate to explain the very high proportion of terrestrial prey in the diet …". Here we present some field observations of surface prey capture of *X. laevis*.

Observations were made during field studies on *Xenopus* in three periods: 1–13 Jan 1994, 9 Jan – 4 Feb 1995, and 3 Jan – 19 Feb 1996. The study site was the "Torchwood Pond" (24°25'S, 30°50'W) near Hoedspruit, NE Transvaal, South Africa. This seasonal pond was 65 m^2 in size, located at the wooded slope of the Drakensberg Mountains at an altitude of 750 m, and contained a native population of about 80–100 *Xenopus*, most of them marked.

On 4 Jan 1994 at 0030 h, flying termites passed the pond and hundreds of them dropped into the water. We observed numerous *Xenopus*, body floating in typical posture of 45° under water and eyes above the water or swimming, locating, and catching the wriggling insects. One male (62 mm SVL) caught eight termites within about 20 min.

Two cases of surface prey capture during light rainfall were recorded at 2030 h on 16 Jan 1995. Probably due to the rain, several small moths (ca. 10–15 mm length) were trapped on the water surface. Some *Xenopus* were floating and swimming at the surface. Within about 10 min, we observed two *Xenopus* collecting one moth each. Size and sex of both *Xenopus* could not be recognized due to the choppy water surface.

At 2230 h on 6 Feb 1996, while observing an adult female *Xenopus* (73 mm SVL), a moving cricket (ca. 30 mm length) was spotted on the water's surface. The female was floating at the surface and started swimming toward the cricket a distance of about 20 cm, caught the cricket, and swallowed it under water.

At 2000 h on 18 Feb 1996, a preying mantis (ca. 70 mm length) dropped from an overhanging branch. A female *Xenopus* (75 mm SVL) sitting in shallow water, started swimming over a distance of about 40 cm and caught the mantis. It took about 10 min for the female to swallow the big insect.

Similar observations were made in several nights in all three study periods, indicating that surface prey capture might be a regular event. The only aquatic invertebrates observed in the pond were a few water bugs (Heteroptera) and hand sized crabs (*Potamon* sp.), suggesting that potential aquatic prey might be limited. Surface prey capture as reported herein may explain, for e.g. confined ponds or lack of aquatic prey, high frequencies of terrestrial invertebrates in the stomach contents of *Xenopus*. It might also explain the ability for excellent analyses of water-surface waves with the lateral-line organs of *Xenopus* (Elepfandt 1996. *In* Tinsley and Kobel [eds.], pp. 98–120, *op. cit.*).

We are indebted to Prof. Duncan Mitchell (Johannisburg) and H. Stander (Hoedspruit) for enabling access to the "Torchwood Pond."

TESTUDINES

CHELODINA OBLONGA (Narrow-breasted Snake-necked Turtle). **PLANKTON FEEDING BEHAVIOR.** The turtle genera *Chelodina, Macrochelodina, Chelus, Hydromedusa* (Chelidae), and *Chitra* and *Pelochelys* (Trionychidae) display a high degree of specialization for catching fast-moving prey like fish and shrimps. All those genera have long necks, elongated and flat heads with rather weak jaws, and forward-positioned eyes that provide good binocular vision. Their feeding behavior involves accurate, fast strikes at prey items and a gape and suck mechanism: an explosive expansion of the throat generates an inrush of water that carries the prey with it. The mouth is then closed to a crack, the water expelled, and the prey swallowed (Legler 1978. Can. J. Zool. 56:2449–2453; Pritchard 1984. Symp. Zool. Soc. London 52:87–110; Thomson 2003. http://www.chelonia.org/Articles/longneck_flathead_evolution.htm). *Chelodina oblonga* has a thick neck and, in relation to body size, the longest neck of all Australasian snake-necked turtles. Its food reportedly consists of small fish, shrimps, freshwater crayfish, aquatic insects, tadpoles, frogs, small water birds, carrion, and some plant material (Burbidge 1967. The Biology of South-western Australian Tortoises. Ph.D. Thesis, The University of Western Australia, Perth. 165 pp.; Cann 1998. Australian Freshwater Turtles. Beaumont Publishing, Singapore. 292 pp.).

On 28 and 29 December 2005 in the early afternoon I observed for several hours *C. oblonga* from a boardwalk across Tomato Lake, a suburban lake of Perth, Western Australia, while they were feeding on undetermined plankton that accumulated in clouds under the water surface at the sun/shade intersection caused by the boardwalk. In water depths of about 1–2 m several groups of 2–6 adult turtles of both sexes were stationary or swam slowly in the lower water zone and repeatedly extended their necks in slow motion upward into the plankton clouds while gaping the mouths wide open and maximally expanding the throats through water intake before closing the mouth to a crack, expelling most of the water and showing swallowing movements of the neck. Individual turtles repeated this behavior in intervals of about 20 seconds. These feeding behaviors of *C. oblonga*, with the necks slowly extending upward and the throats expanding before the necks were pulled back for swallowing, was reminiscent of the slow pulsating feeding movements of other plankton-feeding organisms like baleen whales and whale and basking sharks.. Thus, although the long neck, flat head, and wide throat of *C. oblonga* appear to be adaptations to catch fast-moving prey through a high speed strike combined with gape and suck feeding (Thomson, *op. cit.*), the species can also use its specialized neck and head morphology to ingest masses of slow-moving or near-stationary small planktonic organisms. Until now, this feeding behavior and food source has apparently not been reported for *C. oblonga* or other snake-necked turtles.

CHELONIA MYDAS (Green Seaturtle). **NESTING.** Although Green Seaturtle juveniles have been documented in Virginia's waters, nesting has never been reported (Mitchell 1994. The Reptiles of Virginia. Smithsonian Inst. Press, Washington, D.C.). Excavation of an oviposition site and deposition of 124 eggs by a Green Seaturtle was observed at a public beach in the community of Sandbridge, City of Virginia Beach, Virginia, USA (36.71370°N, 75.93123°W, NAD 83), on 1 August 2005. Because the oviposition site was below the high-tide line and in a heavily used public recreation area, wildlife biologists from nearby Back Bay National Wildlife Refuge excavated the nest and relocated it to a secure site behind the primary dune line on the Refuge. Of the 124 eggs deposited, 120 were relocated. After an incubation period ranging from 58–63 days, 99 hatchlings emerged on 28 September 2005, one on 29 September, eight on 1 October, and six on 3 October (95% success rate). All were released on the same night of emergence. This is the northernmost record of an oviposition site for this species. The previous northernmost nesting record is ca. 77 km S of the Virginia/North Carolina line, near Nags Head, North Carolina (M. Godfrey, Sea Turtle Project, North Carolina Wildlife Resources Commission, pers. comm., 2005). Palmer and Braswell (1995. Reptiles of North Carolina, Univ. NC Press, Chapel Hill) noted that the northernmost locality was at Cape Hatteras, North Carolina. Photos (KU-CT 11959) were taken by Pam Gelman, verified by Joseph Mitchell, and deposited at the University of Kansas.

CHELONIAN SPECIES. RECORD CARAPACE LENGTHS FOR ILLINOIS. Maximum sizes attained by turtles in various portions of their ranges are not often reported. We began trapping and nesting surveys of turtles in west-central Illinois, USA, in 1994 and continued through 2006. During that time we have collected data on 27,206 turtles of ten different species, a total that excludes data collected on hatchlings. In this note we present new state maximum size records (carapace length) for six Illinois species including a range-wide size record for the Red-eared Slider (*Trachemys scripta elegans*).

Turtles were collected in baited hoop traps, unbaited fyke nets, or by hand at nesting areas. Turtles were returned to the laboratory where they were marked, weighed, measured, and then released at the collecting area (Tucker et al. 1998. J. Herpetol. 32:294–298). Only the initial capture for each individual was included in the analysis. Maximum sizes were compared to those in Smith (1961. Illinois Nat. Hist. Surv. Bull. 28:1–298) and Phillips et al. (1999. Illinois Nat. Hist. Surv. Man. 8:xv, 1–282) for Illinois and to Ernst et al. (1994. Turtles of the United States and Canada. Smithsonian Institution Press, Washington, D.C. 578 pp.) and Conant and Collins (1991. A Field Guide to Reptiles and Amphibians. 3rd ed. Houghton Mifflin Co., Boston, Massachusetts. 450

Table 1. Descriptive statistics for ten species of turtles collected in west-central Illinois.

Species	N	Carapace Length Mean (std)/ range	Carapace Width Mean (std)/ range	Carapace Height Mean (std)/ range	Plastron length Mean (std)/ range	Mass Mean (std)/ range
Chelydra serpentina/ Snapping Turtle	468	27.0 (6.4) 3.2–40.5	23.0 (5.3) 3.1–32.5	11.6 (2.7) 1.9–16.8	20.1 (4.5) 2.3–29.7	5940 (3368.7) 10.9–16000

Measurements of length and height are in cm; mass is listed in g.

pp.) along with other more recent references cited below for the United States.

Dimensions for all captured turtles are listed in Table 1. State record carapace lengths were recorded for six species (Table 2). Illinois collecting sitess for each of the record-sized turtles are Swan Lake, Calhoun Co., for the Spiny Softshell (*Apalone spinifera*) and the Common Snapping Turtle (*Chelydra serpentina*); Spunky Bottoms, Brown Co., for the Red-eared Slider (*Trachemys s. elegans*) and the Painted Turtle (*Chrysemys picta*); the Illinois River adjacent to Swan Lake, Calhoun Co., for the Smooth Softshell (*Apalone mutica*); and Gilbert Lake, Jersey Co., for the Stinkpot (*Sternotherus odoratus*). Our size records for female Red-eared Sliders exceeded the previously reported range-wide record for females of 29.2 cm for a specimen from Missouri (Johnson 2000. The Amphibians and Reptiles of Missouri. 2nd ed. Missouri Department of Conservation, Jefferson City, Missouri. 400 pp.). Such large specimens are uncommon, and we collected only three individuals with a carapace length of 30 cm or greater among the more than 24,500

Table 2. Maximum carapace lengths (cm) for turtles from Illinois and the United States. Measurements are for females except where noted.

Species	Current study	Smith (1961)	Phillips et al. (1999)	Ernst et al. (1994)	Conant & Collins (1991)
Apalone spinifera	50.0	28.2	38	54.0	43.2
Apalone mutica	28.8	23.3	28.0	35.6	35.6
*Chelydra serpentina**	40.5	30	N	49.4	49.4
Chrysemys picta	19.5	16.6	18	20.3	25.1
Trachemys s. elegans	30.2	22.9	26	28	28.9
*T. s. elegans**	26.1	N	N	20	N
Sternotherus odoratus	14.6	12.8	13	13.7	13.7

Symbols: * data collected from males; N = not given.

individuals observed. However, other slider subspecies attain much larger carapace lengths (Ernst et al. 1994, *op. cit.*). Our state record for the Stinkpot (Tucker and Lamer 2005. Herpetol. Rev. 36:314) is just slightly smaller than the range-wide record of 15 cm (Ewert 2005. Herpetol. Rev. 36:314) for a specimen from Indiana.

The fairly large number of new state records that we report almost certainly reflects our intensive trapping program. Trapping was mostly conducted in backwaters of the Illinois River rather than in the river itself. Consequently, we caught few map turtles, which are generally riverine species (Dreslik and Phillips 2005. J. Freshwater Ecol. 20:149–164). Our collections of terrestrial turtles such as the Eastern Box Turtle (*Terrapene carolina*) were also small. This is an upland species and not common in the floodplain areas that we surveyed. In contrast, numbers of Sliders dominate our collections. Despite the small numbers of riverine specialists that we examined, we believe it is important to report these records because size in turtles is usually associated with reproductive output and can vary geographically (Iverson 1992. Herpetol. Monogr. 6:25–42; Tucker et al. 1998, *op. cit.*).

Brian J. Towey, Megan Dooling, and Mika Avara helped with trapping. Collecting at the Stump Lake was made possible by Neal Booth and Kim Postlewait (Illinois Department of Natural Resources) at the Mississippi River State Fish and Wildlife Area in Rosedale, Illinois. Access to Swan Lake and Gilbert Lake was made possible by John Mabery (US Fish and Wildlife Service) at the Two Rivers National Wildlife Refuge-Brussels District. Collections at Spunky Bottoms were funded by the Nature Conservancy and we thank Theron Hobson for his assistance. We also thank Jim Beasley, Beasley Fish of Grafton, Illinois for providing bait. Collecting was done under Illinois Department of Natural Resources scientific permit authorization to Tucker.

CHELYDRA SERPENTINA (Common Snapping Turtle). **DIET**. *Chelydra serpentina* is an omnivorous species known to consume a variety of vertebrates, invertebrates, and vegetation (Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Institution Press, Washington D.C. 578 pp.; Palmer and Braswell 1995. Reptiles of North Carolina. UNC Press, Chapel Hill, North Carolina. 412 pp.). Clams and mussels have been listed among the invertebrates taken by *C. serpentina*, yet none has been identified to species. Here we report an instance of predation on a freshwater mussel and provide a positive identification of species.

One of us (SKH) captured a male *C. serpentina* (345 mm CL, 250 mm PL, 9.5 kg) in a small sandy pool near a culvert between two human-made ponds within the Auburn University North Fisheries Unit on 19 September 2005 ca. 3 km N of Auburn, in north-central Lee Co., Alabama, USA (UTM 16 641280E, 36 15474N; datum: WGS 84; elev. 200 m). Upon close examination of the turtle it was observed that freshwater mussel shell fragments were protruding from the cloaca, which appeared to be entirely blocked by this indigestible material. We removed several of the fragments and determined the mussel was *Utterbackia imbecillis*, the Paper Pondshell. *Utterbackia imbecillis* is an ecologically tolerant and widespread pearly mussel (Bivalvia: Paleoheterodonta, Unionoida; Unionidae), common in lentic bodies of water in the Mississippi River drainage basin and the basins of other rivers draining into the Gulf of Mexico (Parmalee and Bogan 1998. The Freshwater Mussels of Tennessee. University of Tennessee Press, Knoxville 328 pp.). The turtle was held for six days, during which time the remaining fragments were passed or removed with forceps. The total dry weight of the *U. imbecillis* shell fragments was 78 g. *Utterbackia imbecillis* shells are notably thinner than those of other unionids and closed shells containing decaying animals are often found floating on the surface of ponds and sluggish rivers during summer and early fall. Although it is possible that these mussels were taken on the substrate surface, we speculate that this turtle encountered and fed upon dead *U. imbecillis* found floating at the surface of these warm, shallow, nutrient-rich ponds.

Submitted by **GEOFFREY G. SORRELL, SHANNON K. HOSS**, and **MICHAEL M. GANGLOFF**, Department of Biological Sciences, 331 Funchess Hall, Auburn University, Alabama 36849-5414, USA (e-mail: sorregg@auburn.edu).

DEIROCHELYS RETICULARIA RETICULARIA (Eastern Chicken Turtle). **TERRESTRIAL REFUGIUM DURATION.** *Deirochelys reticularia* is an aquatic turtle known to hibernate and aestivate terrestrially (Buhlmann 1995. J. Herpetol. 29:173–181). Buhlmann and Gibbons (2001. Chelon. Cons. Biol. 4[1]:115–127) reported that, among 150 *D. reticularia* inhabiting a Carolina bay in South Carolina, terrestrial refugium duration ranged from 121–285 consecutive days, with an average of 185 days. Buhlmann (*op. cit.*) reported a maximum of 156 days spent in terrestrial refugia among six *D. reticularia* radio-tracked in a Virginia population. Here I report an exceptionally long use of terrestrial refugia by *D. reticularia*.

Between 6 September 1998 and 12 February 2006, I radio-tracked 17 *D. reticularia* alternately utilizing a large ephemeral pond, a permanent human-made lake and beaver swamp complex, and interlying terrestrial sandhill habitat, dominated by longleaf pine (*Pinus palustris*), wiregrass (*Aristida stricta*), and scrub oaks (*Quercus* spp.) (Sandhills Game Lands, ca. 17.7 km NW of Wagram, Scotland Co., North Carolina, USA). While all but two of the turtles spent at least some time on land while being tracked, two individuals remained in terrestrial refugia for exceptionally long periods.

A subadult female (straightline CL 109 mm, 177 g) was initially captured in the ephemeral pond on 13 May 2000, taken into the laboratory, fitted with a transmitter on 19 May, and released back into the pond on 20 May. On 26 May she was found in a terrestrial refugium ca. 390 m from the pond. On 28 May she was found to have moved ca. 6 m. She remained in that spot until 4–6 August; on 6 August she was found to have moved ca. 136 m. On 10 February 2001, I replaced her transmitter in the field. On 17 February she was found to have moved 2 m and an additional 11 m on 24 February. She remained in that spot until 13 April; on that date she moved ca. 119 m. On 2 June she was found to have moved ca. 31 m, following a prescribed burn that passed over her refugium between 28 May and 2 June. She remained in that location

until at least 30 March 2002 (her transmitter was again replaced in the field on 27 January 2002). On 24, 29, and 30 March, she was found awake and alert with her head protruding from the leaf litter. On 6 April she was found in the permanent lake/beaver swamp complex, ca. 470 m from her most recent terrestrial refugium and ca. 700 m from the ephemeral pond where she was originally captured. She remained there until her signal was lost on 1 June 2002. This turtle spent a minimum of 674 consecutive days in terrestrial refugia—more than twice the maximum of 285 days reported by Buhlmann and Gibbons (*op. cit.*).

An adult female (CL 180 mm, 689 g) was initially captured while hibernating terrestrially on 24 February 2001, at a point ca. 200 m from the dry ephemeral pond and ca. 500 m from the lake/beaver swamp complex. She was taken into the laboratory, fitted with a transmitter on 2 March, and replaced in her terrestrial hibernaculum on 3 March. She remained in that spot until 18–25 May; on 25 May she was found to have moved ca. 104 m. She remained there until 2 June, when she was found to have moved ca. 36 m, following a prescribed burn that passed over her refugium between 28 May and 2 June. She remained in that spot until 13 April 2002 (her transmitter was replaced in the field on 18 November 2001). On that date she was found moving overland ca. 132 m from her most recent refugium, and on the following day she was found in the beaver swamp complex (ca. 500 m from her original capture site), where she remained until her signal was lost on 13 June 2002. This turtle endured a minimum of 413 consecutive days in terrestrial refugia (almost certainly considerably longer, as she had likely been in terrestrial aestivation/hibernation for several months before being found).

During most of the period these two turtles spent on land, the ephemeral pond was dry or nearly so. The remaining 15 turtles tracked in this population spent periods ranging from zero to at least 259 consecutive days in terrestrial refugia. In all cases, terrestrial refugia were shallow depressions dug by the turtles at, or up to ca. 5 cm below, the surface of the sandy soil. In most cases, when only the surface litter was brushed aside, the top of the turtle's carapace was visible. On the few occasions when I disturbed them, the turtles always appeared awake and would move if touched, even in very cold weather. On at least three occasions, prescribed fires passed directly over turtles without harming them, though the surface litter and survey flags marking the turtles' locations were consumed. Turtles were monitored opportunistically at fairly frequent intervals (an average of ca. every 4–5 days) while in terrestrial refugia, and there was little or no possibility of their having moved to water and then back to their refugia during the short intervening periods.

These observations indicate that *D. reticularia* is strongly drought-resistant and capable of enduring periods of nearly two years in terrestrial refugia. Why some turtles exhibited this behavior rather than moving directly into the lake/beaver swamp complex is unknown. Possibly the permanent water was perceived as suboptimal habitat and only entered as a "last resort" when energy reserves were nearly depleted; however, several individuals migrated directly from the ephemeral pond to the permanent lake, covering the distance (a minimum of ca. 670 m) in less than 24 h.

For support and assistance, I thank the North Carolina State Museum of Natural Sciences, North Carolina Herpetological Society, Wake Audubon Society, Three Lakes Nature Center and Aquarium, North Carolina Wildlife Resources Commission, and the many individuals who assisted with field work—especially Stanley L. Alford, L. Todd Pusser, and Thomas J. Thorp.

GLYPTEMYS INSCULPTA (Wood Turtle). **GENERATIONAL TWINNING**. Twinning has been reported for several species of North American freshwater turtles (Plymale et al. 1980. Florida Sci. 43:97–102; Tucker and Jansen 1997. Copeia 1997:166–173). Twinning in *Gyptemys insculpta* has been reported at least once (Oldfield and Moriarty 1994. Amphibians and Reptiles Native to Minnesota. University of Minnesota Press. 131 pp.) previous to this report. The twin turtles in that report were captive-hatched from a wild-caught gravid female in August 1985.

One of the 1985 twins was raised in captivity and bred annually to a captive-bred female of similar age since 1996. In June 1997, this pair produced a clutch of seven eggs. Three of the eggs were fertile. One of the fertile eggs failed after about 40 days of incubation, one hatched normally at 70 days, and one had not hatched at 90 days. The unhatched egg was opened and found to contain one small live embryo and one dead embryo attached to the same yolk (JFBM 13514). Both embryos appeared normal. None of the subsequent seven clutches from this pair of turtles has produced twins.

This is the first published record of generational twinning in turtles. Previous studies (Tucker and Janzen 1997, *op. cit.*; Yntema 1970. Anat. Rec. 166:491–498; Yntema 1971. Copeia 1971:755–758) only looked at twins produced from wild nests. Additional studies will be needed to determine if generational twinning is genetically based or due to chance developmental anomalies.

GLYPTEMYS INSCULPTA (Wood Turtle). **DIET.** North American Wood Turtles are known to feed opportunistically on a variety of plant and animal species. Food preferences may differ geographically and shift seasonally but include a variety of green leaves, fruits, flowers, fungi, and invertebrates (Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Institution Press, Washington D.C. 578 pp.; Farrell and Graham 1991. J. Herpetol. 25:1–9; Strang 1983. J. Herpetol. 17:43–47). As part of a larger study analyzing home range, movement patterns, and microhabitat usage, I used radio telemetry to observe 15 adult *G. inscuplta* in Butler Co., Iowa (at the southwestern limit of the species' range) from May 2003 to May 2006 and noted feeding events and food sources when possible. Noted Wood Turtle food sources in Butler Co. (listed in order of frequency of observation) included grasses, slugs, violet leaves (*Viola* sp.), prairie ragwort leaves (*Senecio plattensis*), black raspberries (*Rubus* sp.), earthworms, snails, and dandelion leaves (*Taraxacum officinale*). To date, *S. plattensis*, a plant with toxic properties, has not been reported as a food item for *G. insculpta*.

Senecio (=*Packera*) *plattensis* [Asteraceae] is distributed broadly from the east coast to the midwest of North America; its range

overlaps with *G. insculpta* in Iowa, Michigan, Minnesota, New Hampshire, Pennsylvania, West Virginia, Wisconsin, and Virginia. *Senecio plattensis* occurs frequently within the study sites in Butler Co., Iowa; it is found in sandy soil and commonly occurs in clearings in the forest canopy with a variety of grasses, sedges, and forbs, and along riverbanks in mixed species assemblages dominated by *Salix* spp. (saplings) and *Bromus* spp. (grasses). Wood Turtles in Butler Co. frequently utilize both of these microhabitats.

Senecio spp. are known to contain a variety of toxic pyrrolizidine alkaloids (otocecine-type: senkirkine, hydroxysenkirkine, and petasitenine; and retronecine type: jacobine, isatidine, retrorsine, riddelliine, senecionine, and seneciphylline) that are variously hepatotoxic, genotoxic, tumorigenic, carcinogenic, and mutagenic (Fu et al. 2004. Drug Metabolism Reviews 36:1–55). Pyrrolizidine alkaloids (PAs) are produced by over 6000 members of several plant families (Asteraceae, Boraginaceae, Leguminosae) and are reported to be the most common poisonous plant compounds that affect wildlife, livestock, and humans worldwide (Steenkamp et al. 2000. Ther. Drug. Monit. 22:302–306; Stegelmeier et al. 1999. J. Nat. Toxins 8:95–116).

I have only witnessed *G. insculpta* feeding on the ovate basal leaves at ground level, despite the availability of flower heads on short stems. For example, an adult male Wood Turtle (923.6 g, carapace length 186.14 mm) was observed on 15 May 2004 feeding on prairie ragwort; the turtle ate the majority of several basal leaves from two adjacent plants between 1611 h and 1624 h, then moved 0.5 m and partially consumed a dandelion leaf (*Taraxacum officinale*) at 1633 h. The turtle then moved 1.5 m and basked in a stand of willow saplings (*Salix* spp.) until 1740 h. After basking, cloacal temperature was 26.2°C; air temperature was 18.4°C.

Eight adult (two males and six females) *G. inscuplta* have been observed feeding on *S. plattensis* between May 2004 and April 2006. Several individuals have been observed to feed repeatedly on *S. plattensis* and to date none has shown visible signs of acute or chronic toxicity. Of over 870 sightings on 46 marked turtles between May 2003 and May 2006, I have observed only two fatalities, neither related to ingestion of *S. plattensis*.

Pyrrolizidine alkaloid poisoning is apparently unreported for herbivorous reptiles, but is well-documented in numerous insect, fish, bird, and mammal species (Candrian et al. 1984. Food Chem. Toxicol. 22:223–225; Chan et al. 2003. Toxicol. Lett. 144:295–311; Cheeke and Pierson-Goeger 1983. Toxicol. Lett. 18:343–349; Hendricks et al. 1981. Exp. Mol. Pathol. 35:170–183). Barnard (1996. Reptile Keeper's Handbook. Krieger Publ. Co., Malabar, Florida) includes *Senecio* spp. on a list of plants that are poisonous to reptiles, but apparently this is based on toxicity to humans. To my knowledge, it is undetermined if herbivorous reptiles, particularly turtles, exhibit toxicity upon ingesting PAs or if toxicity might be mitigated by enzymatic or bacterial alteration of the toxins.

Funds for equipment were provided by the Department of Biology, University of Northern Iowa, and the Minnesota Herpetological Society. This research was conducted under scientific collecting permit SC-648, Iowa Department of Natural Resources.

GEOCHELONE CARBONARIA (Red-footed Tortoise). **SWIMMING.** The presence of tortoises (Testudinidae) on islands and both sides of large river systems suggests that they must be capable of swimming or, at a minimum, floating to facilitate passive transport in currents. It has been suggested that tortoises float due to their high carapace height-to-width ratios (Patterson 1973. J. Herpetol. 7:373–375), yet few published accounts exist that document swimming activity by tortoises. Swimming accounts have been published for *Geochelone nigra* (Beebe 1924. Galapagos World's End. Putnam's Sons, London), *Gopherus polyphemus* (Brode 1959. Herpetologica 15:101–102; Carr 1952. Handbook of Turtles: The Turtles of the United States, Canada, and Baja California. Cornell Univ. Press. Ithica, New York), *Geochelone* (*Testudo*) *gigantea* (Gaymer 1968. J. Zool. 154:341–363), and *Testudo graeca* (Gasith and Sidis 1982. Copeia 1982:200–201). Although these tortoises are not particularly well-shaped for swimming, several of these authors noted that the tortoises float quite buoyantly, are capable of keeping their head above water, and are capable of controlling their direction of movement, in some cases in the presence of a current (Brode, *op. cit.*; Carr, *op. cit.*; Beebe, *op. cit.*; Gaymer, *op. cit.*).

On 17 May 2006, at 1650 h, an adult female *G. carbonaria* (ca. 35 cm linear carapace length) was observed swimming across the Uraricoera River (a third-order tributary to the Amazon River, located in Roraima State, northern Brazil) from the mainland to the 110,000 ha riverine island, Maracá Ecological Reserve. The tortoise was observed by JNS from a boat for ca. 10 min as it was carried downstream by the current, yet making progress towards the opposite bank of the 150 m wide river, as it alternately paddled with its forelimbs. The tortoise's head and top one-third of its carapace were above water (Fig. 1), but when approached too closely, the tortoise stopped swimming and held its head below water for ca. 30 sec. A juvenile *G. carbonaria* of unknown sex (22 cm linear carapace length) was also observed swimming and was captured for measurement in the same river as it arrived close to the island shore at ca. 1300 h on 12 June 2004.

The island towards which both of these tortoises were swimming has both *G. carbonaria* and *G. denticulata*, suggesting that both species are capable of swimming, although this is yet to be documented for the latter. To our knowledge, this is the first report

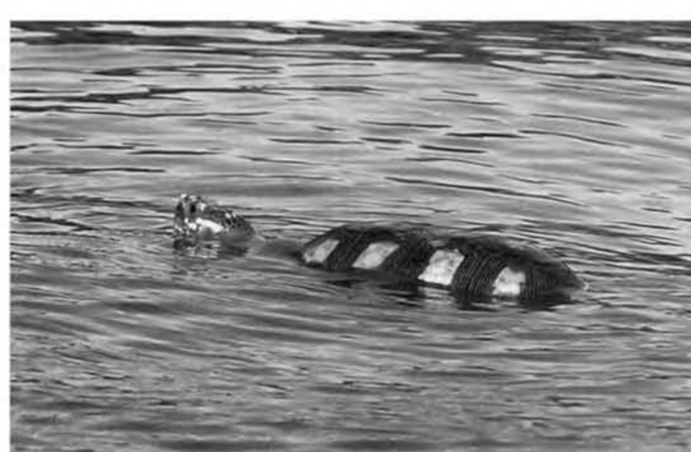

FIG. 1. Female *Geochelone carbonaria* swimming across the Uraricoera River, Roraima State, northern Brazil, 17 May 2006.

of *G. carbonaria* actively swimming.

Research in 2004 was supported by grants from the Wildlife Conservation Society Research Fellowship Program, Chelonian Research Foundation Linnaeus Fund, and Sigma Xi Grants in Aid of Student Research to JNS. We thank F. A. Franco de Medetrus for observations of the juvenile tortoise.

Submitted by **JOEL N. STRONG**, Zoology Department, University of Hawaii at Manoa, 2538 McCarthy Mall, Honolulu, Hawaii 96822, USA (e-mail: joelstrong78@yahoo.com); and **ANDREW D. WALDE**, P.O. Box 36, Helendale, California 92342, USA (e-mail: awalde@hotmail.com).

HEOSEMYS SPINOSA (Spiny Hill Turtle). **DIET**. *Heosemys spinosa* is reportedly primarily herbivorous in the wild, though captives accept both plant and animal matter (Lim and Das 1999. Turtles of Borneo and Peninsular Malaysia. Natural History Publications [Borneo] Sdn. Bhd., Kota Kinabalu. xii + 151 pp.; Pritchard 1979. Encyclopedia of Turtles. TFH Publications, Neptune, New Jersey. 895 pp.). However, apparently there are no published studies on the natural diet of this species. Fecal samples from four individuals (two females, one male, one juvenile) were analyzed for content. Three animals (a male, a female, and a juvenile) originated from Kubah National Park (01°33'N, 110°12'E), Sarawak, Malaysia (Borneo). A fourth (a female) was from the vicinity of Balai Ringin (01°03'N, 110°45'E), a fishing village also in Sarawak. The three individuals from Kubah had seeds of an indeterminate type of plant as well as other plant material, and parts of indeterminate insects. The fecal sample from the adult female from Balai Ringin contained plant material, unknown insect parts, vertebrae from an unidentified fish species, several phalanx bones from a monkey, either a macaque (*Macaca* sp.) or a langur (*Presbytis* sp.), presumably taken by scavenging.

We thank the Sarawak Biodiversity Centre for permission to collect turtles and the Sarawak Forest Department and Sarawak Forestry Corporation for support. The Universiti Malaysia Sarawak supported our research on the turtles of Borneo through grant number 1/26/303/2002 (40), and the Earl of Cranbrook and Phil Piper assisted with the identification of the primate bones.

HYDROMEDUSA TECTIFERA (South American Snake-necked Turtle). **ALTITUDINAL RECORD**. The geographic distribution of South American snake-necked turtles (*Acantochelys radiolata*, *Hydromedusa maximiliani*, *H. tectifera*, and *Phrynops hogei*) and their habitat preferences are still inadequately defined, and these turtles' populations are being reduced because of environmental disturbances (Ernst and Barbour 1989. Turtles of the World. Smithsonian Institution Press, Washington, DC 313 pp.; Rocha et al. 2000. *In* Bergallo et al. [Orgs.], A Fauna Ameaçada de Extinção do Estado do Rio de Janeiro, pp. 79–87. EdUERJ). These species typically inhabit rivers, lakes, and swamps along the coastal lowlands from Brazil to Argentina (Achaval and Olmos 2003. Anfíbios y Reptiles del Uruguay. 2da. Edición corregida y aumentada. Graphis, Montivideo, Uruguay. 136 pp.; Ernst and Barbour, *op. cit.*; Pritchard 1979. Encyclopedia of Turtles. TFH Publ. Co., Neptune, New Jersey. 895 pp.). On 15 September 2001 at 0915 h, a male *Hydromedusa tectifera* (carapace length ca. 20 cm) was found resting underwater (water temperature 17.8°C) at a depth of 50 cm at the Poço Verde (22°30'S, 43°02'W; 450 m elev.), in the Parque Nacional da Serra dos Órgãos, Rio de Janeiro State, Brazil. The turtle was captured and identified for JALP and JPF, photographed, and then released. This finding constitutes the highest elevation for which this species has been recorded.

KINOSTERNON SCORPIOIDES ALBOGULARE (White-throated Mud Turtle). **FEEDING BEHAVIOR AND DIET.** The feeding behavior and diet of *Kinosternon scorpioides albogulare* was studied at the Caribbean island of San Andres, Colombia, during a survey of the population conducted from March to July 2002. On this island these turtles inhabit both freshwater ponds and mangroves, with more than 98% of the total population living in the latter (Forero-Medina, Chelon. Cons. Biol., *in press*). Direct observations on feeding behavior were conducted during the study, and stomach flushing (Legler 1977. Herpetologica 33:281–284) was used on 50 individuals for determining dietary composition. Stomach contents were preserved in alcohol, and the items were identified to taxonomic category. The turtles displayed both diurnal and nocturnal feeding activity. A nocturnal pattern occurring at the fresh water ponds, where it is almost impossible to observe an individual during the day. In the mangroves, however, they were frequently seen active during the day. Most of the stomachs were found to be empty, but some of them contained identifiable items. These included seeds, coleopteran elytra, small gastropods, arthropods, and larval crustaceans (zoea) and dipterans. These last two items were found in large quantities in some specimens. During observed feeding events, the identified prey were a small fish and an aquatic coleopteran in the freshwater ponds, and a fruit (*Annona* sp.) on the floor of a mangrove habitat. Turtles were also frequently observed ingesting organic wastes such as coconut leftovers, disposed by people living next to the mangroves. These results suggest that the species is omnivorous and opportunistic and that it uses resources such as fruits or arthropods depending on their availability.

Feeding in *K. s. albogulare* can be terrestrial or aquatic. Carr and Mast (1988. Trianea [Act.Cient.Tecn. INDERENA] 1:87–97) suggested that the terrestrial invertebrates consumed by *K. herrerai* had likely fallen onto the water; however, our observations on *K. s. albogulare* confirm both aquatic and a terrestrial feeding behavior. A notable item found in the diet of some individuals is a large quantity of dipteran larvae. A study on the feeding behavior of *K. s. cruentatum* (Monge-Najera and Moreva-Brenes 1987.

Herpetol. Rev. 18:7–8) found a strong preference for eating mosquito larvae; one individual consumed 148 in 24 h. These results suggest that turtles could play a role in the control of mosquitoes on the island. They could also be contributing to nutrient cycling processes in the mangroves as they consume organic waste and dead animals such as crabs, as observed by one of us (Castaño, unpubl.). Continued studies may reveal additional items consumed by the species and seasonal and temporal changes in dietary preferences.

PHRYNOPS HILARII (Hilaire's Side-necked Turtle). **REPRODUCTION.** A number of factors are known to influence the incubation time and size of chelonian neonates (Kohler 2005. Incubation of Reptile Eggs. Krieger Publ. Co., Malabar, Florida. 214 pp.). However, much reported data is based on artificially incubated eggs, where eggs are exposed to constant temperatures during the incubation period. Here I present data on the longest known incubation period of a *Phrynops hilarii* clutch in non-controlled environment.

A female *Phrynops hilarii* was found after it had been hit by a vehicle in a road in southern Rio Grande do Sul state, Brazil. The animal was still alive but later died in the laboratory. This female had a carapace length (CL) of 338 mm, plastron length of 299 mm, and a body mass of 3600 g. Upon necropsy, fourteen intact eggs were found in its oviducts, six in the right side and eight in the left side. Egg measurements showed low variability, both in diameter (greater dimension: mean = 33.6 ± 0.477, lesser: mean = 32.0 ± 0.350) and weight (mean = 20.5 ± 0.489 g). Total egg mass represented approximately 9% of the body mass of the female. Initially, egg viability was considered unlikely, and the eggs were placed in a closed jar and kept on a shelf exposed to ambient room temperatures. This room was heated during the coldest winter months, while in summer, air conditioning was turned on only during working hours in the laboratory.

Of the 14 eggs placed in the jar, 10 hatched successfully, one hatchling died during hatching, two eggs contained dead embryos in different stages of development, and one was classified as nonviable due to absence of visible embryonic development. Hatching was verified after a period of 418 days. Of the 10 successful hatchlings, CL of nine ranged between 41 and 42.6 mm, and one was notably smaller at CL 38.8 mm (N = 10; mean = 41.3; SD = 1.03; Min. = 38.8; Max. = 42.6). No abnormalities in scute pattern were observed. Incubation periods of 100–300 days have been reported for turtles in this genus, with ± 150 days being noted for captive-bred *P. hilarii* (Fabius 2004. Manouria 7[25]:28–38). Reports that this species might deposit eggs during two laying periods in fall and spring (March–May, September–December) with a single hatching period in late summer or fall suggests that *P. hilarii* embryos might enter a state of diapause under certain conditions (R .Vogt, pers. comm.; Fabius, *op. cit.*). This might explain the survival of embryos under presumably stressful conditions and extended incubation period reported here.

Submitted by **ALEX BAGER,** Laboratório de Manejo e Conservação Ambiental da Universidade Católica de Pelotas, Rua Félix da Cunha, 412, Pelotas, RS, 96010 000, Brazil; e-mail: abager@uol.com.br.

TRACHEMYS SCRIPTA ELEGANS (Red-eared Slider). **REPRODUCTION.** The natural range of *Trachemys scripta elegans* is centered in the south-central United States, from Illinois to the Gulf of Mexico. Because of its prominence in the international pet trade, the species now can be found over much of the United States, and its introduction has been documented throughout the world (Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Institution Press, Washington. 578 pp.). There has been speculation as to whether and where introduced Red-eared Sliders can reproduce in the wild in California (Bury and Luckenbach 1976. Biol. Conserv. 10:1–14). Successful nesting or presumed breeding (i.e., gravid females) in northern California were reported by Bury and Luckenbach (*op. cit.*) at Clear Lake, by Spinks et al. (2003. Biol. Cons. 113:257–267) at the University of California, Davis, and by Fidenci (2006. Herpetol. Rev. 37:80) in the Mount Tamalpais Watershed, Marin Co. Here, we report additional evidence of reproduction in *T. s. elegans* in the wild in northern California.

On 27 April 2001, MPB and R. Corwin found a hatchling *T. s. elegans* in a fyke net set for salmonid surveys at Stony Creek, immediately upstream from its confluence with the Sacramento River, Glenn Co.. This area is southeast of the city of Orland. The turtle was 41 mm CL (straight-line carapace length). On 31 May 2001, in a slough about one mile east of Stony Creek, GML captured a hatchling *T. s. elegans* (53 mm CL). In this same remote area, GML has captured, marked, and released 88 *T. s. elegans*, seven of which were <100 mm CL. Over the course of a two-year mark-recapture study in 2004 and 2005 on the eastern half of the Bufferlands in Elk Grove (city), Sacramento Co., LCP captured 240 individual *T. s. elegans*, 18 of which were <100 mm CL (smallest = 34.6 mm CL). On 17 June 2005, E. Meyer, W. Wegner, and D. Degross visited a pond on the north side of the Sacramento River, Redding (city), Shasta Co. Several adult *T. s. elegans* and Pacific Pond Turtles (*Actinemys marmorata*), the native turtle, were observed basking on logs in the pond. One adult male *T. s. elegans* (139 mm CL) was captured in a small turtle trap baited with canned sardines. One hatchling *T. s. elegans* (34.8 mm CL), of four observed basking on a log in the shallows, was captured with a dip net.

The observation of multiple hatchling and juvenile *T. s. elegans* reported here, along with previously cited reports, suggests that successful reproduction is occurring in the wild in northern California and that these young turtles were wild-bred and not released pets.

Stebbins (2003. Western Reptiles and Amphibians. 3rd ed. Houghton Mifflin Co., Boston, Massachusetts. 533 pp.) noted that *T. s. elegans* has been introduced into California's Central Valley (Sacramento-San Joaquin drainages). This watershed encompasses a considerable proportion of lowland habitats and, until recently (see Fidenci, *op. cit.*), included all of the prior and present cases of

successful breeding of *T. s. elegans* in northern California. To date, known cases of reproduction in *T. s. elegans* in northern California are in or near urban areas, where it is more likely that pet turtles will escape or be released. The mild Mediterranean climate of the Central Valley may facilitate the survival and successful breeding of introduced *T. s. elegans*. With these additional sightings of reproduction in northern California, it appears that established populations of *T. s. elegans* are more widespread than previously recognized. Further research should focus on whether introduced populations of Sliders are a potential threat to the native *A. marmorata*.

Research was conducted under Scientific Collecting Permits from the California Department of Fish and Game, under authorization of the Department of Water Resources, and with approval to conduct surveys in the City of Redding and Sacramento County. We thank Richard Corwin, Doug Degross, Erik Meyer, and Willow Wegner for their help in the field.

CROCODYLIA

CAIMAN CROCODILUS (Spectacled Caiman). **PREDATION/EAVESDROPPER.** The use of mating signals by unintended receivers, or eavesdroppers, is a widespread phenomenon and has been documented in several signal modalities (Zuk and Kolluru 1998. Quart. Rev. Biol. 73:415–438). Several predators and parasites use mating calls of other species to locate their prey/host. Male frogs calling to find a mate are known to attract predators such as frog-eating bats (*Trachops cirrhosus*: Tuttle and Ryan 1981. Science 214:677–678; Ryan and Tuttle 1983. Anim. Behav. 31:827–833) and opossums (*Philander opossum*: Tuttle et al. 1982. Biotropica 13:233–234), and parasites such as blood-sucking flies (*Corethrella* spp.: McKeever 1977. Mosquito News 37:522–523). Here, I report observations of eavesdropping on advertisement calls of frogs and toads by *Caiman crocodilus* from Gamboa (9°07.0'N, 79°41.9'W, datum: WGS84; elev. 35 m), Panama.

The diet of *C. crocodilus* includes a wide variety of foods; young caiman eat mostly aquatic arthropods (insects and crustaceans), whereas adults feed mainly on fishes and frogs (Savage 2002. The Amphibians and Reptiles of Costa Rica. University of Chicago Press, Chicago. 934 pp.). Yet, no reports exist on what cues caimans use to find the frogs they eat. Given that *C. crocodilus* hunt at night when most frogs call, their use of prey-emitted cues seems likely. *Caiman crocodilus* are known to be attracted to distress calls of the Smokey Jungle Frog, *Leptodactylus pentadactylus* (LeVering 1999. Unpubl. Ph.D. dissertation, University of Texas, Austin). LeVering (*op. cit.*) showed that *L. pentadactylus* frogs under attack produce distress calls that resemble the calls produced by young caimans. Such distress calls attract adult Spectacled Caimans, some of which interfere and may increase the probability of the frog escaping.

Between 1 and 14 August 2005, I observed the responses of two adult and two juvenile *C. crocodilus* to playbacks of frog advertisement calls. I broadcast calls of four species of frogs common in the area of Gamboa (Panama) from a speaker placed at ground level. I played a series of calls of 5–10 individuals of each species for 30 min with the purpose of trapping blood-sucking flies, *Corethrella* spp., that are attracted to advertisement calls of frogs. Only calls of one frog species were played during each 30-min interval, and calls were presented at the call rate at which they were originally recorded.

When I was setting up the trap to collect flies between 2010 and 2245 h on 1 August 2005, I noticed an adult (ca. 200 cm TL) *C. crocodilus* in a small pond 10–12 m from the pool of water next to which I had placed the trap. I first broadcast calls of *Eleutherodactylus diastema*, a small arboreal frog, and only a few *Corethrella* flies were attracted. I then played the calls of *L. pentadactylus,* and when I returned to close the trap I found an adult *C. crocodilus* by the trap, looking directly at the speaker (Fig. 1). The caiman had displaced the speaker about 10 cm and claw marks were present on the ground nearby. When I approached the trap, the caiman went back to the pond where I originally saw it at the beginning of the evening. After that, I played calls of *Agalychnis callidryas*, a slender medium-sized treefrog, but did not attract caiman. Finally, I broadcast calls of the toxic toad *Bufo marinus* and a caiman, apparently the same one based on overall morphology, approached the speaker again. On 10 August 2005, another adult (ca. 170 cm TL) caiman in an area about 100 m away approached a speaker playing *B. marinus* calls. On both nights, the caimans that approached the speaker moved it with their head and feet and scratched the area around it with their claws. On 2 and 14 August 2005 between 2000 and 2200 h, I broadcast calls of *L. pentadactylus* and *B. marinus* at 30-min intervals to juvenile caimans (ca. 70 cm TL) that were within 7–10 m of the speaker. In no case did the small caimans move in the direction of the calls.

FIG. 1. Adult *Caiman crocodilus* attracted to a speaker broadcasting *Leptodactylus pentadactylus* calls. The trap was originally intended to attract *Corethrella* flies.

These observations suggest that adult *C. crocodilus* use advertisement calls of frogs to locate their prey. Further, they seem to selectively approach terrestrial frogs large enough to offer a substantial meal (e.g., *L. pentadactylus* and *B. marinus*). Studies that further investigate caiman prey selectivity based on advertisement calls of frogs are necessary to confirm this observation. Crocodilians other than Spectacled Caimans are known to feed on frogs and toads (*Crocodylus acutus*: Savage, *op. cit.*; *Crocodylus moreleti*: Perez-Higareda et al. 1989. Copeia 1989:1039–1041). For instance, Morelet's Crocodiles have a diverse diet that includes *B. marinus* and *Rana vaillanti* (Perez-Higareda et al., *op. cit.*). Hence, use of prey-emitted cues by crocodilians that feed heavily on anurans deserves exploration.

These observations were possible thanks to the support of the Smithsonian Tropical Research Institute (STRI) through a fellowship conducted to study *Corethrella* flies in the same area. I thank Bill Wcislo for his support as STRI sponsor and Mike Ryan for referring me to the study done by Kate LeVering. Marc Hayes provided valuable comments that improved this manuscript.

LACERTILIA

ANOLIS ALLISONI (Allison's Anole/Camaleón Azul). **NECTAR FEEDING**. As recently as the ecological review in Schwartz and Henderson (1991. Amphibians and Reptiles of the West Indies: Descriptions, Distribution, and Natural History. University of Florida Press, Gainesville. 720 pp.), nectarivory among anole lizards remained undocumented. Yet, over the last decade, more attention has been paid to lizard behavior when they are near flowers, resulting in scattered evidence for polychrotid lizards feeding on nectar and/or pollen (e.g., *Anolis carolinensis*: Bartlett 1995. Reptiles 2:48–65; Himes 1998. Herpetol. Rev. 29:236; Campbell and Bleazy 2000. Herpetol. Rev. 31:239; *A. conspersus*: Echternacht et al. 2000. Herpetol. Rev. 31:173; *A. grahami*: Losos and Queiroz 1997. Natural History 108:34–39; *A. porcatus*: Townsend 2003. Herpetol. Rev. 34:141–142; and *A. stratulus*: Perry and Lazell 1997. Herpetol. Rev 28:150–151). Cuban anoles may seem an exception to this pattern, but the many dietary studies on Cuban anoles, based almost entirely on stomach contents analyses (e.g., review in Rodríguez-Schettino 1999. The Iguanid Lizards of Cuba. University of Florida Press, Gainesville. 384 pp.) rather than behavioral observations, have provided little opportunity to record nectarivory. However, two anoles native to Cuba have been identified as nectar feeders in Florida: *A. porcatus* (an introduced species) on the ornamental Areca Palm (*Chyrsalipedocarpus lutescens*; Townsend, *op. cit.*), and the native *A. carolinensis* on two native palms: *Serenoa repens* and *Sabal palmetto* (Campbell and Bleazy, *op. cit.*). For this reason, I document nectarivory in *A. allisoni* in Cuba.

Between 0830 and 0930 h on 17 June 2003, I observed several females and juveniles of *A. allisoni* lapping nectar from the flowers of the ornamental palm 'Adonidia' (*Veitchia merrillii*, Arecaceae) in a garden in the Balcón de la Sierra (Bartolomé Masó). This palm is native to the Philippines but is common in Cuba (Leiva 1999. Las Palmas en Cuba. Ed. Científica-Técnica. La Habana, Cuba. 84 pp.). In this garden, *A. allisoni* is relatively abundant, and the species is often seen (often 3–4 on the same trunk) climbing these palms at heights < 2 m. On 10 occasions, females and juveniles were observed visiting flowers for nectar. Although several males were present in different palms at similar heights as females and juveniles, I never observed them visiting flowers during this period. My observation is similar to behavioral data obtained in captivity, where juveniles of different Cuban anoles have been observed feeding on nectar directly from flowers (L.V. Moreno, pers. comm.). In this garden, flowers of *V. merrillii* were also frequently visited by honeybees, but I did not observe aggressive interactions between lizards and bees, although on one occasion, a juvenile *A. allisoni* left when a honeybee arrived at the same flower. Remaining lizard-plant interactions occurred without *Apis mellifera* presence.

An insectivorous diet has been reported for *A. allisoni*, both in island (Cuba) (Rodríguez-Schettino, *op. cit.*) and mainland (Mexico) situations (Lee 1996. The Amphibians and Reptiles of the Yucatan Peninsula. Comstock Publ. Assoc., Ithaca, New York. 500 pp.). This observation documents a new example of lizard nectar feeding in island habitats, where this phenomenon has been observed relatively more frequently than in mainland situations (Olesen and Valido 2003. Trends Ecol. Evol. 18:177–181), and where lizards have the potential to act as pollinators. Lizard pollination of plants has been experimentally demonstrated in but a few cases (e.g., the lacertid *Podarcis lilfordi* from the Balearic Islands [Traveset and Sáez 1997. Oecologia 111:241–248; Pérez-Mellado and Casas 1997. Copeia 1997:593–595], and the scincid *Niveocincus microlepidotus* in Tasmania [Olsson et al. 2000. Biol. J. Linn. Soc 71:191–202]), but together with scattered indirect evidence from New Zealand (Whittaker 1987. New Zealand J. Bot. 25:315–328; Eifler 1995. Oecologia 101:228–233), Mauritius (Nyhagen et al. 2001. J. Trop. Ecol. 17:755–761), the Canary Islands (Fong and Ferrer 1995. Herpetol. Rev. 26:35–36; Valido et al. 2002 Acta Oecologica 23:413–419), New Caledonia (Bauer and Sadlier 2000. The Herpetofauna of New Caledonia. SSAR Publications, Ithaca, New York. 310 pp.), and the Seychelles (Cheke 1984. *In* Stoddart [ed.], Biogeography and Ecology of the Seychelles Islands, pp. 331–360. W. Junk Publishers, The Hague), these observations imply that greater attention should be paid to the possibility of lizard pollination (Proctor et al. 1996. The Natural History of Pollination. Harper Collins, London. 479 pp.).

Here, I reported nectarivory by a Cuban anole on an exotic palm. However, if we consider the abundance of palms in Cuba (about 80 native species; Leiva, *op. cit.*) along with the ability of *Anolis* to exploit nectar from palm flowers and hummingbird feeders (*A. carolinensis*: Liner 1996. Herpetol. Rev. 27:78), or bottles of honey left open in houses in Cuba (*A. porcatus*: A. Fong., pers. comm.), interactions between anoles and native palms that involve nectarivory and perhaps pollination should be expected.

I thank Lourdes Rodríguez-Schettino, Luis Moreno, and Ansel Fong for their assistance on Cuban anole information, and Ramona Oviedo and Gabriel Brull for hospitality and palm identification. Funding was provided by Marie Curie grant (MCFI-2000-1995).

ANOLIS SAGREI (Cuban Brown Anole). **PREDATION**. Native to Cuba and the Bahamas, *Anolis sagrei* was first observed in the Florida Keys in the 1880s, and by the 1970s had spread across Florida (Meshaka et al. 2004. The Exotic Amphibians and Reptiles of Florida. Krieger Publishing, Malabar, Florida. 155 pp.). *Anolis sagrei* seems to flourish in disturbed habitats but can inhabit nearly any habitat in Florida (Campbell 2003. Herpetol. Rev. 34:173–174). Little is known of the ecology of its introduced populations, but indigenous predators may have a controlling effect. Here we report the first observation of a Red-shouldered Hawk (*Buteo lineatus*) preying on *A. sagrei.*

At ca. 1400 h on 7 May 2006, we observed an adult *B. lineatus* capture and eat an adult (ca. 14 cm total length) *A. sagrei*. Our observation was made in an old-growth cypress (*Taxodium distichum*) strand on the edge of a small (ca. 10 × 10 m) pool, located near the end of the Big Cypress bend boardwalk (25°56'49"N, 81°28'9"W, datum NAD 83: elev. 2 m) in Fakahatchee Strand State Park. We initially saw the hawk in flight, then it perched ca. 3 m above the ground on a *T. distichum* branch. It remained in this position for ca. 15 min, then flew down to the ground and seized the body of the *A. sagrei* with its talons. The *A. sagrei* was quickly consumed whole and the hawk flew to another perch and preened its talons and flight feathers. From capture to ingestion, the episode took ca. 50 sec.

Prior to this observation, the Broad-winged Hawk (*Buteo platypterus*) was the only other raptor reported to prey on *A. sagrei* in Florida (Meshaka et al., *op. cit.*). *Buteo lineatus* forages both above and below the canopy, searching for prey from the air or a perch (Stevenson and Anderson 1994. The Birdlife of Florida. University Press of Florida, Gainesville, Florida. 892 pp.). The wide variety of prey items in the diet of *B. lineatus* indicates that it is not a prey specialist (Stevenson and Anderson, *op. cit.*; Bednarz and Dinsmore 1985. Can. Field Nat. 99:262–264). The diet may change seasonally in relation to food availability, but mammals, lizards, and amphibians are the most common categories of prey items delivered to nests (Bednarz and Dinsmore, *op. cit.*). We commonly found *B. lineatus* perched on branches in old-growth cypress strand, a kind of diurnal perch at which individuals are cryptic. In Florida, A. *sagrei* perches in trees and shrubs but is most often found close to, or directly on, the ground (Meshaka et al., *op. cit.*) and will escape by running along the ground, perhaps in part because the primary predator avoidance behavior is avoiding a predator's visual field (Regalado 1998. Carib. J. Sci. 34:211–217). The use of uncovered microhabitat by *A. sagrei* increases its likelihood of predation by this Florida raptor.

We thank Marc Hayes and Walter Meshaka for suggested revisions to the text.

ARTHROSAURA RETICULATA (Reticulated Creek Lizard). **PREDATION.** The Amazon Fishing Spider (*Ancylometes rufus*, Pisauridae) is an opportunistic predator of small vertebrates (e.g., fishes, frogs, and tadpoles; Azevedo and Smith 2004. *In* Borges et al. [eds.], Janelas para Biodiversidade no Parque Nacional do Jaú, pp. 135–142. Fundação Vitória Amazônica, Manaus; Menin et al. 2005. Phyllomedusa 4:39–47). Here, we present the first report of *A. rufus* preying on the gymnophthalmid lizard *Arthrosaura reticulata*.

The observation occurred at 1430 h on 12 December 2002 at Reserve Adolpho Ducke, in the municipality of Manaus, State of Amazonas, Brazil (02°54'S, 59°53'W, datum: WGS 84; elev. 78 m). We encountered an adult male *A. rufus* (32.9 mm TL) in terra-firme forest, motionless and camouflaged in the leaf-litter, capturing a young male *A. reticulata* (37.8 mm SVL) that passed nearby. The spider secured the body of the lizard with its chelicerae, whereupon the lizard immediately autotomized its tail. While we attempted to collect the spider, it released the lizard. The lizard survived, remaining motionless, for ca. 4 min before succumbing to the effects of the spider's venom. These two species occur in similar habitats near bodies of water (Avila-Pires 1995. Zool. Verh. Leider. 299:1–706; Höfer and Brescovit 2000. Insect Syst. Evol. 31:323–360), which may facilitate this occasional intraguild predation.

The *A. reticulata* (INPA-H 16058) and the *A. rufus* were deposited in the herpetological and invertebrate collections, respectively, of the Instituto Nacional de Pesquisas da Amazônia. T. R. Gasnier verified the identity of the *A. rufus*.

Submitted by **FABIANO WALDEZ** (e-mail: fwaldez@inpa.gov.br) and **MARCELO M. LIMA** (e-mail: marcelo_inpa@hotmail.com), Instituto Nacional de Pesquisas da Amazônia (INPA), Campus II, Coleção de Anfíbios e Répteis. Av. André Araújo, 2936. CP. 428. CEP 69.083-000 Manaus, Amazonas, Brazil.

ASPIDOSCELIS LINEATISSIMUS (Colima Whiptail Lizard). **PREDATION.** *Aspidoscelis lineatissimus* inhabits Tropical Dry Forest in Pacific Mexico from Nayarit to Guerrero (García and Ceballos 1994. Fundación Ecológica de Cuixmala-Instituto de de Biología UNAM, México; Smith and Taylor 1950. Bull. U.S. Natl. Mus. 199:1–253). The Mexican government regards this species as requiring special protection, a criterion established under the authority of the Secretaria de Recursos Naturales y Medio Ambiente (NOM-SEMARNAT-059-2001). Several investigators have studied *A. lineatissimus* (Walter 1970. Herpetologica 26:359–365; Ramirez-Bautista and Uribe-Peña 1989. Herpetol. Rev. 20:70; Ramirez-Bautista 1994. Manual y Claves Ilustradas de los Anfibios y Reptiles de la Region de Chamela, Jalisco. Tesis Doctoral, Facultad de Ciencias, Universidad Nacional Autonoma de México; Ramirez-Bautista et al. 2000. Copeia 2000:712–722), but data on predators are lacking. Hence, we report an observation of *Salvadora mexicana* predation on *A. lineatissimus* from coastal Jalisco, México.

During a herpetofaunal survey on 16 October 2004, we photographed an adult (85 cm SVL) male *S. mexicana* consuming an adult (ca. 16 cm SVL) male *A. lineatissimus* in the municipality of La Huerta, 65 km N of Barra de Navidad (19°31'24.2"N, 105°02'11.7"W, datum: NAD 27; elev. 47 m). The snake was not collected. SG made the observation near the margin of the Chamela River; dominant riparian vegetation included *Crescentia alata*, *Astianthus viminalis*, *Tabebuia chrysantha*, *Coccoloba* sp., *Lonchocarpus* sp., and *Thouinidium decandrum*. Tropical Decidu-

ous Forest dominates upland vegetation in the area (Lott 2002. *In* Noguera et al. [eds.], Historia Natural de Chamela, pp. 99–136. Instituto de Biología, Universidad Nacional Autonoma de Mexico, Ciudad de Mexico; Raymundo Ramírez-Delgadillo, pers. comm.). When first observed, the snake had already begun feeding on the lizard, which was being ingested headfirst. When about 40% of the lizard had been ingested, the snake released the lizard, presumably to better reposition it to continue swallowing. Ultimately, the snake swallowed the lizard; the feeding sequence we were able to observe took ca. 25 min.

Salvadora mexicana, which occurs in several vegetation associations along the Pacific Coast of Mexico from Nayarit to Oaxaca (Garcia and Ceballos, *op. cit.*), has a diet that is incompletely understood, but Bogert (1939. Publ. Univ. California Los Angeles Biol. Sci. 1:177–236) reported that a *S. mexicana* secured by Walter Mosauer at Tierra Colorada (Guerrero) had eaten an adult *Cnemidophorus* (= *Aspidoscelis*) *guttatus*. Moreover, other species of *Salvadora* are known to eat whiptails and racerunners (Coues 1875. Rept. Geog. Geol. Expl. Surv. West 100th Meridian 5:585-633; Bogert, *op. cit.*), which likely reflects a pattern in the genus.

CALEDONISCINCUS HAPLORHINUS (Strand Litter Skink). **PREDATION.** *Caledoniscincus haplorhinus* is a small skink endemic to New Caledonia that has been reported primarily from the southwest coast from Nouméa to Pindaï and Pouembout with scattered records further north. Records on the east coast are few, but this probably reflects a lack of collecting effort in the appropriate habitat in this area. This skink occurs also on most islands in the region including Ouvéa, Maré, and Lifou in the Loyalties, and on Île Surprise and the Belep Islands off the northern end of New Caledonia. It seems absent from Île Huon, the northernmost part of New Caledonia territory and from the Isle of Pines (Bauer and Sadlier 2000. The Herpetofauna of New Caledonia. Society for the Study of Amphibians and Reptiles in cooperation with the Institut de Recherche pour le Développement. 310 pp.). No data exist on its predators (Bauer and Sadlier, *op. cit.*), although other large skinks (e.g., *Lioscincus nigrofasciolatum* and *Phoboscincus garnieri*, both likely syntopic with *C. haplorhinus*) are anticipated predators. Here we report a case of predation on *C. haplorhinus* by an avian predator.

At ca. 1000 h on 28 November 2005, RLG observed and photographed an adult *Todiramphus sanctus canacorum* (Sacred Kingfisher) carrying an adult (ca. 45 mm SVL) *C. haplorhinus* in his bill (Fig. 1). This bird species was regularly seen bringing skinks to feed its chicks in a nest located in the lower part of a dead Coconut Tree (*Cocos nucifera*) along the beach. The observations took place on Islet Beautemps-Beaupré (20°24'35"S, 166°08'30"E, datum: WGS 84; elev. 5 m).

CNEMASPIS KENDALLII (Kendall's Rock Gecko). **PREDATION**. Myrmecophagy, consumption of ants as prey, is a common nutritional strategy among amphibians and reptiles (e.g., poison dart frogs—Caldwell 1996. J. Zool. [London] 240:75–101; desert horned lizards—Blackshear and Richerson 1999. Texas J. Sci. 51:147–152). The reverse strategy, ants actively preying on living amphibians and reptiles rather than just scavenging on their remains, is something for which we have found no evidence in the literature. We have heard anecdotes according to which groups of foraging ants, including army ants as well as other species, opportunistically attacked small frogs and lizards, and even hatching tortoises (*Testudo graeca*; Y. Werner, pers. comm.). However, to the best of our knowledge predation by a solitary ant on an amphibian or reptile has never been reported in the literature. This is not surprising since, ordinarily, amphibians and reptiles outsize

ants. However, size may not limit predation by ants on lizards where giant ants exist. For this reason, we report an observation of predation by a giant ant on a gecko from Peninsular Malaysia. At ca. 1500 h on 24 July 2003, during a visual survey for reptiles and amphibians in lowland dipterocarp forest (Grismer et al. 2004. Asiatic Herpetol. Res. 10:244–276) along the Tekek-Juara Trail on Pulau Tioman, Pahang State (2°49'N, 104°10'E; elev. 125 m) a solitary individual of the Malaysian Giant Forest Ant (*Camponotus gigas*) was observed carrying an unusually large prey item in its mandibles. This species is one of the world's largest ants, reaching nearly 3 cm total body length. It is known to engage in ritual combat (Pfeiffer and Linsenmair 2001. J. Ethol. 19:75–85), and procurement of sizeable prey items is not unusual for an aggressive species such as this. Close examination of the relatively fresh, partially digested, fleshy mass revealed the prey item to be a small individual of the saxicolous gecko *Cnemaspis kendallii* (specimen collected and its identity verified by L. Lee Grismer). During our herpetological survey work in the rainforest of Pulau Tioman, we have frequently observed individuals of *C. gigas* crisscrossing the leaf litter, either as a means of surveying an area surrounding a colony or on solitary foraging excursions. During such forays, these ants cover some of the habitat used as hiding places by *C. kendallii*. We presume that the gecko captured by this ant fell victim to a chance encounter, since ordinarily a gecko would easily outrun an ant. However, a small *C. kendallii* would probably not be able to outwrestle the powerful mandibles of these ants.

COPHOSAURUS TEXANUS (Greater Earless Lizard). **MORTALITY**. Prey selection among lizards involves decisions made during pursuit and capture that have positive consequences when food is acquired but potentially negative consequences if the intended prey presents injury-producing or life-threatening antipredator defenses (Sherbrooke 2002. Herpetol. Rev. 33:312). Hence, we document the death of a *Cophosaurus texanus* that may be the result of ingested prey.

At 1206 h on 15 May 2005 near the Indio Mountains Research Station headquarters 40 km SW of Van Horn, Hudspeth Co., Texas, USA (30°46'35"N, 105°00'55"W, datum: WGS 84; elev. 1215 m), we observed a gravid female *C. texanus* (65 mm SVL, 33 mm tail, partly regenerated) moving erratically on the floor of an arroyo within a Chihuahuan Desert scrub habitat. Despite our approach, the lizard never attempted to flee. Failure to flee was also peculiar because it was exposed to elevated midday air temperatures in full sun; ambient air temperature was estimated to be ca. 35°C, and substrate temperature undoubtedly greater. Such conditions would normally have compelled the lizard to flee a potential predator (our presence) or to find a shaded refuge. Instead, when the lizard made forward movements, which occurred several times during our observation, it would pause, close its eyes, and then slowly shift its head from side to side. The lizard died after 14 min of

FIG. 1. Female *Cophosaurus texanus* and two honeybees (*Apis mellifera*) removed from the contents of its stomach. The honeybee on the left is shown for comparison.

displaying that behavior fully exposed to unshielded sunlight. External inspection of the lizard revealed no signs of injuries, trauma to the skin, or subcutaneous bleeding, so we assumed that its death was probably not the result of predator attack.

Necropsy confirmed lack of physical trauma to the lizard, and inspection of its stomach revealed that it had recently fed on the following undigested insect prey: one ant (Formicidae), one beetle (Coleoptera), two termites (Isoptera), two bugs (Rophalidae), one mantis (Mantidae), two sweat bees (Halictidae) and two worker honeybees (Apidae: *Apis mellifera*; Fig. 1). Prior investigations of *C. texanus* diet (Barbault 1978. La Terre et la Vie. 32:135–150; Barbault and Maury 1981. Oecologia 51:335–342; Maury 1981. *In* Barbault and Halffter [eds.], Ecology of the Chihuahuan Desert: Organization of Some Vertebrate Communities, pp. 119–142. Publ. Instituto de Ecología, Mexico; Smith et al. 1987. Great Basin Nat. 47:175–185; Maury 1995. J. Herpetol. 29:266–272; Kasson 2001. Herpetol. Rev. 32:40) have not reported honeybees. Moreover, we initially noticed that both bee stingers were detached from their bodies, which would be the case if envenomation had occurred in a normal defensive manner (Caron 1999. Honey Bee Biology and Beekeeping. Wicwas Press, Cheshire, Connecticut. 355 pp.). One stinger was later found imbedded in the mouth lining and the other in the stomach. Hence, our observation suggests that the lizard died after being stung subsequent to ingesting the two honeybees. Whether death was directly caused by venom toxicity or alternatively by the lizard becoming disoriented and behaviorally incapacitated by the toxin, which eventually led to a fatal state of overheating, is not known.

Both the preserved lizard and its stomach contents were deposited in the Laboratory for Environmental Biology, Centennial Museum, The University of Texas at El Paso (UTEP 19226). We thank Paul Lenhart for prey item identification.

Submitted by **VICENTE MATA-SILVA** (e-mail: vmata@utep.edu), **JERRY D. JOHNSON**, and **ALEJANDRO JUAREZ-REINA**, Department of Biological Sciences, The University of Texas at El Paso, Texas 79968, USA.

***ENYALIUS* SP.** (NCN). **PREDATION.** Species of *Enyalius* usually use a combination of cryptic coloration and immobility to avoid predation (Pianka and Vitt 2003. Lizards: Windows to the Evolution of Diversity. University of California Press, Berkeley. 333 pp.). However, herein we describe the first predation records on an undescribed species of *Enyalius* from Brazilian cerrado by a Black-tufted-ear Marmoset (*Callithrix penicillata*).

Observations occurred on 21 September and 4 October 2005 at Jardim Botânico de Brasília, Distrito Federal, Brazil (15°51'38.15"S, 47°49'51.20"W, datum: WGS 84; elev. 1127 m), in an area of mesotrophic "cerradão" forest. In the first observation, the dominant female of a *C. penicillata* group was first observed at a height of ca. 1 m eating an *Enyalius* sp. by the head; the latter appeared to be a female based on the dorsal color pattern of paravertebral stripes. The marmoset continued eating the rest of the body while her two infants produced begging calls and attempted to reach the lizard without success. The predation event was observed for 47 min, with the female marmoset being constantly interrupted by her group mates' harassment.

In a second observation, the same dominant female was again sighted at a height of ca. 1 m eating another *Enyalius* sp. by the head. In this case, the dorsal color pattern, consisting of lozenges, did not allow sex identification. After a few attempts one of the subordinate females stole the lizard from the dominant animal, and was able to eat the remaining parts of the body, which included the hind limbs and tail. Both marmosets were observed eating the lizard for a total time of ca. 35 min.

We thank to Jardim Botânico staff for fieldwork authorization and to CAPES and CNPq for financial support.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). **DIURNAL BURROWS; REFUGIA.** *Hemidactylus turcicus*, an introduced species found throughout the southeastern United States (Conant and Collins. 1998. Reptiles and Amphibians of Eastern/Central North America. 3rd ed., Houghton Mifflin Co., Boston, Massachusetts. 450 pp.), typically is associated with buildings and other human structures (Rose and Barbour 1968. Am. Midl. Nat. 79:159–168; Dundee and Rossman 1989. Amphibians and Reptiles of Louisiana. Louisiana State University Press, Baton Rouge. 295 pp.). Known for its arboreal habits with adults foraging higher on walls than juveniles (Gomez-Zlatar and Moulton 2005. Florida Sci. 68:206–214; Paulissen and Buchanan 1991. J. Arkansas Acad. Sci. 45:81–83), information on its terrestrial behavior is limited. Hence, we describe an observation of a group of *H. turcicus* occupying a rock pile in the Liberty Eylau region of Texarkana (33°20.066'N, 94°05.189'W, datum: NAD 27; elev. 162 m), Bowie Co., Texas, USA.

At ca. 1600 h on 3 May 2006, we were moving a large pile of flagstone located in a overgrown rock garden on a 2-ha field situated in a rural-urban interface. Immediately to the south are ca. 518 ha of grazed grassland and forest abutting the Sulfur River. Immediately to the north is a residential area composed of lots from 0.1 to 1.21 ha. The rocks were scattered no more than four stones deep and located ca. 25 m from the nearest building. The pile encompassed an area of ca. 5 × 3 m and was overgrown with native and introduced vegetation including Day Lilies (*Hemerocallis* sp.), Evening Primrose (*Oenothera lamarckiana*), Pink Wood Sorrel (*Oxalis regneli*), and various grasses.

The rocks were removed one at a time and piled into a cart. The first *H. turcicus* was observed under a large (ca. 1 m) diameter flagstone stacked on top of several smaller (ca. 30 cm) flagstones. We continued to remove stones and observed four more *H. turcicus* prior to removing all but the rocks in direct contact with the ground. Of the 12 similarly sized rocks (ca. 30 cm each) located on the ground, three harbored *H. turcicus* in what appeared to be burrows. All *H. turcicus* appeared to be adults (ca. 50–60 mm SVL). The first burrow was linear and tube-shaped (139 mm × 20 mm) with an entrance positioned at the edge of the flagstone, under which the burrow was located. The second burrow was also tube-shaped but had a 90° bend located 100 mm from the entrance (also positioned at the edge of the respective piece of flagstone) creating an L-shaped tube (131 mm × 17.2 mm). In both burrows, the rock formed the burrow roof under which it was constructed. The sides and base of the burrows were composed of a sandy loam typical of Bowie Co. A third *H. turcicus* was observed in a refugium under a rock, but this refugium did not have the tube structure of the other burrows. This third refugium was dish-shaped and ca. 60 mm in diameter. It was unclear whether this structure was a burrow or simply a space that the *H. turcicus* chose to occupy. Upon removal of the rocks, no *H. turcicus* were observed in the immediate vicinity of the original rock garden where they were released or in the cart where the rocks had been deposited through 11 May 2006. This final observation suggests these animals abandon their burrows if disturbed.

This cluster of observations suggests that *H. turcicus* is not restricted to buildings, and may even be more abundant in other kinds of habitats near human dwellings. These observations suggest that positioning rock gardens near homes can provide important habitat for this species. Further, removal of or aversion to providing such potential habitat may be an important tool for removal or suppression of populations of this introduced invasive species.

Submitted by **MALCOLM L. McCALLUM** (e-mail: malcolm.mccallum@tamut.edu) and **JAMIE L. McCALLUM**, Biological Sciences Program, Texas A&M University-Texarkana, 2600 Robison Road, Texarkana, Texas 75501, USA.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). **PREY; PREDATION.** Invasive species are becoming an increasingly important consideration for conservation, but how invasive species interact with one another remains poorly understood. We contribute to that understanding with an observation of *Hemidactylus turcicus* predation on the Red Fire Ant (*Solenopsis invicta*) immediately followed by fire ant predation on the same animal.

Hemidactylus turcicus is a small insectivorous gecko widely distributed by human activities (Wojcik et al. 2001. Am. Entomol. 47:16–23), common throughout the mid-southern United States. The Red Fire Ant, the most widely distributed of two *Solenopsis* species introduced in the United States (http://ipmworld.umn.edu/chapters/lockley.htm, last visited on 11 May 2006), is thought to

be in competition with the regional herpetofauna for various prey (Wojcik et al., *op. cit.*; Hook and Porter 1990. Southwest. Nat. 35:477–478). Documentation also exists for *S. invicta* predation on snakes (Wojcik et al., *op. cit.*), *Bufo houstonensis* (Wojcik et al., *op. cit.*), turtles (Buhlmann and Coffman 2001. J. Elisha Mitchell Sci. Soc. 117:94–100; Moulis 1997. Chelonian Conserv. Biol. 2:433–436; Montgomery 1996. Bull. Chicago Herpetol. Soc. 31:105–106), *Aspidoscelis sexlineatus* nests (Mount et al. 1981. J. Alabama Acad. Sci. 52:66–70; Donaldson et al. 1994. Texas J. Sci. 46:98–113), and large segments of a local herpetofauna (Mount 1981. J. Alabama Acad. Sci. 52:71–78). Aggression by *S. invicta* has also been reported on *Alligator mississippiensis* (Allen et al. 1997. J. Herpetol. 31:318–321; Reagan et al. 2000. J Herpetol. 34:475–478), *Caretta caretta* (Allen et al. 2001. Florida Entomol. 84:250–253), and *Gopherus polyphemus* (Wetterer and Moore 2005. Florida Entomol. 88:349–354). These observations indicate that *S. invicta* can be an aggressive herpetovore.

At ca. 2300 h on 2 August 2005, a juvenile (ca. 30 mm SVL) *H. turcicus* was foraging on fire ants on our back porch (33°20.066'N, 94°05.189'W, datum: NAD 27, elev. 162 m) in Bowie Co., Texas, USA. I observed the animal feed on 6–7 ants and then left. Upon returning 20 min later, I found the animal engulfed in ants. By 0750 h the next morning, the *H. turcicus* was skeletonized. I collected the skull (length 12.2 mm, width 7.8 mm, height 4.9 mm) and deposited it in my private research/teaching collection (MLM 1).

This observation suggests that interspecific predator-prey dynamics exist between sympatric populations of *H. turcicus* and *S. invicta*.

Submitted by **MALCOLM L. McCALLUM** (e-mail: malcolm.mccallum@tamut.edu) and **JAMIE L. McCALLUM**, Biological Sciences Program, Texas A&M University-Texarkana, 2600 Robison Road, Texarkana, Texas 75501, USA.

HOLBROOKIA MACULATA (Earless Lizard). **NECROPHILIA.** To our knowledge, reports of mating or attempted mating with a dead conspecific or heterospecific individual among squamates are confined to only three species: the Australian skink, *Tiliqua rugosa* (How and Bull 1998. Herpetol. Rev. 29:240), the Brazilian snake, *Tachymenis brasiliensis* (Amaral 1932. Mem. Int. Butantan 7:91–94), and the Long-nosed Leopard Lizard, *Gambelia wislizenii* (Fallahpour 2005. Herpetol. Rev. 36:177–178). Here, we report an observation of this behavior in *Holbrookia maculata* from northwest Texas, USA.

A large population of *H. maculata* exists on the edges of the roads in Rita Blanca National Grassland in extreme northern Texas. We studied this population while conducting research on the thermal regimes of this and several other lizard species of similar size. We recorded surface temperatures on the roads as high as 46°C, while surface temperatures of the bordering grasses were 27°C. These conditions offer a wide thermal gradient in which to function, an advantage that may attract this *H. maculata* population to the road margins.

On 14 June 2005 at 1730 h, a male *H. maculata* living along State Highway 296 (36°26.831'N, 102°44.454'W, datum: WGS 84; elev. 1307 m) was observed copulating with a dead conspecific female. The female had been spotted the previous day dead on the side of the road. Apparently, she had been partially run over by a car on 13 June, although her injuries were not extensive and her body, although moderately desiccated, was still intact. Her eyes were sunken and she was unequivocally dead. The male was observed grasping the female by the back of the neck and dragging her in short 1–2 cm jerks across the asphalt. His tail was raised and his right hemipenis appeared to be everted, although it was not clear if copulation was actually successful. This behavior persisted for at least 3–4 minutes but ceased when the researchers approached. A second male *H. maculata* was sighted ca. 0.5 m away. The second male appeared to be observing the attempted copulation and possibly had mated or was waiting to mate with the deceased female.

H. maculata breed in the spring and produce 1–2 clutches per season, depending on the age of the female (Jones and Ballinger 1987. Ecology 68:1828–1838). During the breeding season, females vary their coloration to signal courtship receptiveness or rejection, having low-intensity color early in the season and high-intensity pigmentation late in the season once they have mated (Hager 2001. J. Herpetol. 35:624–632). The behavior reported here implies that the coloration of this immobile female was adequate to induce attempted copulation.

LIOLAEMUS cf. ELONGATUS (NCN). **BODY TEMPERATURE.** *Liolaemus cf. elongatus* inhabits the east slope of the Andean Cordillera in central-western Argentina (Morando et al. 2003. Syst. Biol. 52:159–185). Based on molecular evidence, this taxon, for which formal description is pending, is part of the "*petrophilus* group" clade within the *Liolaemus elongatus-kriegi* complex (Avila et al. 2004. Herpetologica 60:187–203). Its biology has not been addressed. Hence, here we present preliminary data on *L. cf. elongatus* thermal ecology.

In December 2004 and February 2005, we conducted field work in the Parque Nacional San Guillermo, Departamento Iglesia, Provincia de San Juan (29°15'S, 69°29'W, datum: WGS 84; elev. 3700 m), located in the Puna Phytogeographic Province. *Stipa speciosa var. breviglumis, Lyciun chanar,* and *Adesmia* spp. dominate the largely Andean flora (Cabrera and Willink 1980. Biogeografía de América Latina. Washington, D.C. 109 pp.). The data presented are based on 16 captures. To collect these data, we revisited a randomized selection of bushes and low rocks across the study site. Each individual was captured by hand, and its SVL was measured to the nearest 0.05 mm. Sex was not determined in the field because obvious sexual dimorphism was lacking. For each capture, cloacal (T_c), substrate (T_s) and air (T_a) temperatures were measured to nearest 0.1°C with a rapid-reading Miller-Weber thermometer. We took T_s at the exact point of observation, and T_a 1 cm above the substrate, both immediately following capture. We also recorded microhabitat type for each capture.

Of 26 individuals observed, 16 were captured. Mean SVL was 59.8 mm (SD = 9.5, range: 41–72, N = 15). Mean body temperature of the 16 *L. cf elongatus* was 32.0°C (SD = 2.5°C, range = 28.0–36.6°C). Mean air temperature was 29.3°C (SD = 5.6°C, range = 21.0–41.6°C). Mean substrate temperature was 35.4°C

(SD = 11.1°C, range: 22.0–57.0°C). Body size was unrelated to T_c (Spearman Rank Correlation: r_s = -0.05, P = 0.84, N = 15). Cloacal temperature and T_a were significantly correlated (Spearman Rank correlation: r_s = 0.69, P = 0.002), but T_c and T_s were not (Spearman Rank correlation: r_s = 0.43, P = 0.09). Most lizards were found on rocks (N = 16), the remainder being found under vegetation (7), on vegetation (2) or in burrows (1).

Based on the correlations among T_c, T_s, and T_a, *Liolaemus cf elongatus* seems heliothermic, similar to *L. wiegmanni* (Martori et al. 1998. Rev. Esp. Herpetol. 12:19–26) and *L. sanjuanensis* (Acosta et al. 2004. Herpetol. Rev. 35:171). In contrast, body temperature in *Liolaemus elongatus* was positively and significantly correlated with both T_a and T_s (Ibargüengoytía and Cussac 2002. Herpetol. J. 12:131–134). This species thermoregulates over a narrow range of temperature by moving among microhabitats having different temperature, i.e., basking and shuttling behavior.

LIOLAEMUS LUTZAE (Sand Lizard). **PREDATION**. The liolaemid lizard *Liolaemus lutzae* is endemic to the "restingas" (coastal sand dune habitats) of the State of Rio de Janeiro, southeastern Brazil (Vanzolini and Ab'Saber 1968. Pap. Avuls. Zool. São Paulo 21:205–208) and is included in the Brazilian checklist of the fauna threatened with extinction as critically endangered (Machado et al. 2005. Lista da Fauna Brasileira Ameaçada de Extinção. Fundação Biodiversitas, Belo Horizonte. 157 pp.). Information regarding *L. lutzae* predators is restricted to a few records of interspecific predation (e.g., the birds *Guira guira* and *Athene cunicularia* and the ghost crab *Ocypode quadrata*) and cannibalism (Rocha 1992. Herpetol. Rev. 23:60; Rocha and Vrcibradic 1998. Cienc. Cult. 50:364–368). Here we report predation of *L. lutzae* by the snake *Philodryas patagoniensis* (Colubridae). This snake is very common in restinga habitats and is known to prey on lizards in this environment (Rocha and Vrcibradic, *op. cit.*).

At 1035 h on 23 April 2006, during population monitoring of *L. lutzae* on the sand beach habitat at the restinga of Jaconé (22°56'S, 42°40'W, datum: WGS 84; elev. 2 m), municipality of Saquarema, Rio de Janeiro, we found, under a piece of wood, a young female *P. patagoniensis* (267 mm SVL, 371 mm total length, 15.2 g) with a considerably expanded abdomen, suggesting recent prey ingestion. At the same place there was a live *Liolaemus lutzae,* which promptly escaped. We collected the snake, and posterior dissection revealed that it had ingested a juvenile male *L. lutzae* (54.5 mm SVL, 5.2 g) headfirst. The lizard was undigested, implying a recent ingestion. This is the first record of *L. lutzae* as prey of *P. patagoniensis*, which constitutes an additional source of mortality for this endangered lizard.

The snake and its prey were deposited at the reptile collection of the Museu Nacional do Rio de Janeiro, Universidade Federal do Rio de Janeiro (MNRJ 14122). Mara C. Kiefer and Davor Vrcibradic provided suggestions on the manuscript. Fundação Biodiversitas/CEPAN (Project 078H/022004) and CNPq provided funding (Processes # 307653/03 and 477981/03), and CCS received a graduate fellowship from FAPERJ.

Rua São Francisco Xavier, 524, Maracanã, CEP 20550-013, Rio de Janeiro, RJ, Brazil.

LIOLAEMUS OLONGASTA (NCN). **REPRODUCTION.** *Liolaemus olongasta* is an oviparous lizard inhabiting the hot arid landscape of the Monte Phytogeographic Province in northern Argentina (Cabrera and Willink 1980. Biogeografía de América Latina. Washington, DC. 109 pp.). Known from extreme western La Rioja Province and San Juan Province at 900–1600 m elevation (Etheridge 1993. Museo Regionale di Scienze Naturali 11:1–199), data on its biology are sparse. Limited study has been devoted to thermoregulation, sexual dimorphism, and time budgets (Cánovas et al. 2001. Congreso Argentina Herpetol. IV:32–33; Cánovas et al. 2002. Reunión de Com. Herpetol. Asoc. Herpetol. Argentina XVI:45; Cánovas et al. 2003. Reunión de Com. Herpetol. Asoc. Herpetol. Argentina. XVII:38). Hence, we add the first data addressing *L. olongasta* reproductive ecology.

We conducted fieldwork in a temporary creekbed near La Laja (31°19'S, 68°41'W, datum: WGS 84; elev. 700 m) Albardón Department, San Juan Province, Argentina. Data were collected every 10 days from August 2000 to August 2001 by a random pattern of revisits across the study site. Each animal was measured (SVL) and dissected for gonadal examination. In females, we recorded the number of developing follicles and oviductal eggs, the length and width of oviductal eggs, and the condition of the oviducts. In males, we recorded the width and length of testes to enable calculation of volume based on Dunham (1983. *In* Huey et al. [eds.], Lizard Ecology, pp. 261–280. Harvard Univ. Press, Cambridge, Massachusetts). Testicular volume and volume of eggs were natural log-transformed to accommodate their curvilinear functions (King 2000. J. Herpetol. 34:148–150.). Clutch size was determined from the combined number of developing follicles and eggs in the oviducts. We used the simultaneous presence of developing follicles and enlarged oviducts to suggest that more than one clutch was produced seasonally. The smallest female with vitellogenic follicles or oviductal eggs was used to estimate SVL at maturity. Males were considered sexually mature if they contained enlarged epididymides. All measurements were obtained to the nearest 0.02 mm with Vernier calipers.

Forty-three females ranged in size from 23–58 mm SVL; minimum reproductive size was 47 mm. Female body size was correlated with clutch size (Spearman: r_s = 0.64, P = 0.045, N = 10). Clutch size averaged 3.8 (SD = 1.93, range 1–8, N = 10). Between September and October, we recorded four females with developing follicles and enlarged oviducts simultaneously.

Forty-one males ranged in size from 32–62 mm SVL, minimum reproductive size was 49 mm. Testicular volume was positively correlated with body size (r^2 = 0.31, $F_{1,39}$ = 17.81, P = 0.0001, N = 41). Testicular volume varied through the gonadal cycle

(ANCOVA: $F_{9,30} = 6.5$; $P = 0.0001$; N = 41; covariate SVL). Maximum testicular volume occurred in November; the minimum was found in March.

Our data indicate that *L. olongasta* produces more than one clutch a year, as is the case with *L. darwinii* (Blanco et al. 2001. Congreso Argentina Herpetol. IV:26–27), *L. koslowskyi* (Aun et al. 1993. Cuad. Herpetol. 12:1–9), and *L. wiegmanni* (Vega 1999. Ecología de saurios arenícolas de las dunas costeras bonaerenses. Tesis doctoral, inédita, Universidad Nacional de Mar del Plata. 102 pp.). Mean clutch size of *L. olongasta* is similar to that for *L. darwinii* (mean 4.9, range 2–8, N = 40), *L. riojanus* (mean 4.2, range 3–6, N = 15) (Blanco et al. 2001., *op. cit.*; Blanco et al. 2003. Reunión de Com. Herpetol. Asoc. Herpetol. Argentina. XVII:31), *L. koslowskyi* (mean 4.2, range 3–9, N = 53) (Aun et al., *op. cit.*), *L. wiegmanni* (mean 4.6, range 4–5, N = 19), *L. multimaculatus* (mean 4.2, range 3–7, N = 29), *L. gracilis* (mean 4.7, range 4–6, N = 19) (Vega, *op. cit.*), and *L. sanjuanensis* (mean 4.5, range 3–6, N = 5; Marinero et al. 2005. Herpetol. Rev. 36:452). Reproductive activity in this species is spring–summer.

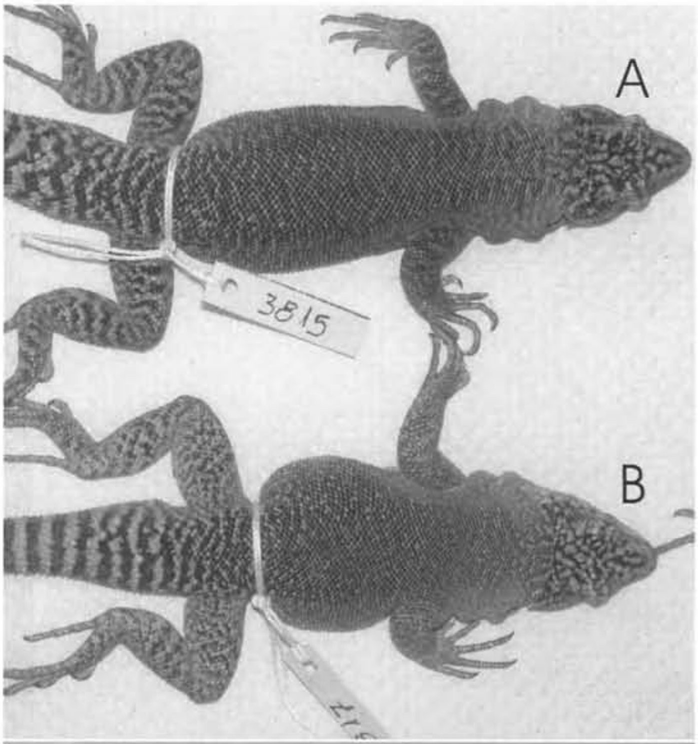
All specimens (IMCN-UNSJ 4015–4099) were deposited in the herpetology collections of Instituto y Museo de Ciencias Naturales of Universidad Nacional de San Juan.

Submitted by **MARIA GABRIELA CÁNOVAS** (e-mail: gabrielacanovasa@yahoo.com.ar), **HÉCTOR JOSÉ VILLAVICENCIO** (hjvillavicenciomartin@yahoo.com.ar)*, **JUAN CARLOS ACOSTA**, and **JOSÉ ALBERTO MARINERO**, Departamento de Biología e Instituto y Museo de Ciencias Naturales, Facultad de Ciencias Exactas, Físicas y Naturales, Universidad Nacional de San Juan. *Becario CONICET, Avenida España 400 (N), Caixa Postal 5400, San Juan, Argentina.

LIOLAEMUS PETROPHILUS **(Stone-loving Lizard). SCOLIOSIS.** Scoliosis and other malformations of the vertebral column like kyphosis are well known in turtles (Rhodin et al. 1984. Brit. J. Herpetol. 6:369–373; Stuart 1996. Bull. Chicago Herpetol. Soc. 31:60–61) and captive iguanas (Otero Llende and Bengoa Rodríguez 2001. Res. VII Congr. Anual Soc. Española Med. Veterinaria, pp. 24–30), but infrequently reported in wild populations of lizards (Mitchell and George 2005. Herpetol. Rev. 36:183–184). Most malformations reported for lizards include bifurcations of the tail, usually as a result of injuries (Scott 1982. Herpetol. Rev. 13:46, Smith 1946. Handbook of Lizards. Cornell Univ. Press, Ithaca, New York. 557 pp.). Here we provide the first report of scoliosis in a liolaemid lizard.

On February 2006, we caught an adult male *Liolaemus petrophilus* (75 mm SVL) on basaltic formations located 31.4 km N Gan Gan, Departamento de Telsen, Chubut (42°22'57.9"S, 68°10'45.4"W, datum: WGS 84; elev. 1246 m). The lizard exhibited a deformation over the pelvic girdle (Fig. 1). This lizard appeared to experience no obvious limitations in prey capture or mobility as it was maintained in captivity several weeks for thermoregulation experiments.

Voucher specimen (LJAMM 3817) is deposited in collection Luciano Javier Avila Mariana Morando (LJAMM) now housed in Centro Nacional Patagónico (CENPAT-CONICET), Puerto Madryn, Argentina.



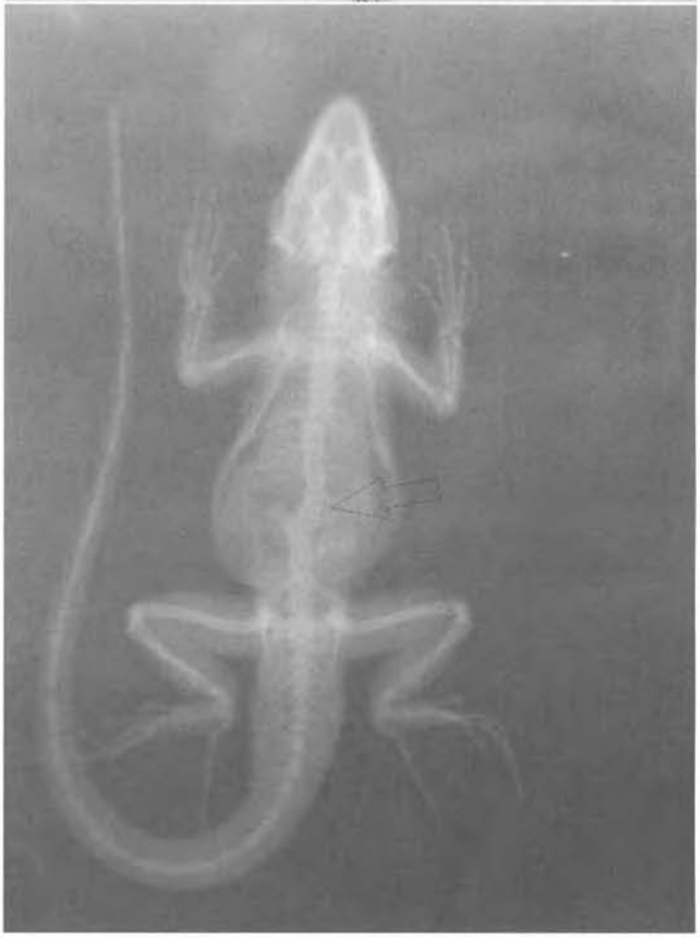


FIG. 1. Upper: Normal (A) and scoliotic (B) male *Liolaemus petrophilus*. Lower: Radiograph of the scoliotic individual; arrow indicates the area of deformity.

Submitted by **NICOLAS FRUTOS** (e-mail: frutos@cenpat.edu.ar), **MONICA KOZYKARISKI** (e-mail: kozykariski@cenpat.edu.ar), and **LUCIANO JAVIER AVILA** (e-mail: avila@cenpat.edu.ar), CENPAT-CONICET, Boulevard Almirante Brown s/n, U9120ACV, Puerto Madryn, Chubut, Argentina.

LIOLAEMUS USPALLATENSIS (NCN). **CLUTCH SIZE.** *Liolaemus uspallatenisis*, a small lizard in the "*darwinii* complex" (Etheridge 1993. Boll. Mus. Reg. Nat. Sci., Torino 11:137–199), is distributed in Mendoza and San Juan provinces, Argentina. This species occurs in rocky, high-elevation habitats dominated by xerophyllous vegetation (*Larrea cuneifolia*, *Lycium* sp., and *Stipa* sp.). Other than it being oviparous, no reproductive data exist (Cei 1986. Reptiles del Centro, Centro-oeste y Sur de la Argentina. Herpetofauna de Zonas Áridas y Semiáridas. Museo Regionale di Scienze Naturali Torino. Monografie IV. 527 pp.). Hence, we report the first data on clutch size in *L. uspallatensis*.

On 17 December 2005, we captured a gravid female (58 mm SVL) *L. uspallatensis* at Barrealito Blanco, Iglesia Department, San Juan Province (30°30'S, 69°10'W, datum: WGS84; elev. 2519 m). This female was placed in a 60 × 50 × 40 cm terrarium with abundant leaves and gravel. On 24 December 2005, the female laid three eggs. The length and width of each egg were measured with Vernier calipers to the nearest 0.01 mm. The volume of each egg was calculated using the formula of an ellipsoid sphere (Dunham 1983. *In* Huey et al. [eds.], Lizard Ecology, pp. 261–280. Harvard University Press, Cambridge, Massachusetts). The eggs averaged 1.37 cm (s = 0.46) in length, 0.77 cm (s = 0.46) in width, and 0.24 cm^3 (s = 0.02) in volume. Clutch size may typically be small in this species as another female *L. uspallatensis* that had been trapped also produced three eggs (JCA, unpubl. data).

The eggs were deposited in the herpetological collection of the Institute and Museum of Natural Sciences of San Juan National University, San Juan, Argentina. We thank Eduardo Sanabria for capturing this specimen.

Submitted by **ALEJANDRO LASPIUR** (e-mail: laspiursaurus@gmail.com) and **JUAN CARLOS ACOSTA**, Departamento de Biología e Instituto y Museo de Ciencias Naturales, Facultad de Ciencias Exactas, Físicas y Naturales, Universidad Nacional de San Juan, Avenida España 400(n), Caixa Postal 5400, San Juan, Argentina.

MABUYA UNIMARGINATA (Central American Mabuya). **REPRODUCTION.** *Mabuya unimarginata* are live bearers with a litter size of 4–9 born in June–July (Lee 1996. The Amphibians and Reptiles of the Yucatán Peninsula. Cornell University Press, Ithaca, New York. 500 pp.). Here I report an observation that might indicate a broader birth interval.

At 1135 h on 25 April 2004, I captured an adult female (82 mm SVL, 12.4 mm tail, 12 g) *M. unimarginata* with six totally formed young (mean SVL = 32 mm). The skink was found near of a temporary pond surrounded by tropical deciduous forest, ca. 4 km SW from Ejido Caobas, Quintana Roo, México (18°26'04"N, 89°07'06"W, datum: NAD 27), elev. 150 m.

Based on their size, the unborn young were a few millimeters smaller than the known size of *M. unimarginata* neonates (ca. 35 mm; Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna Between Two Continents, Between Two Seas. The University of Chicao Press. 934 pp.). This implies parturition during the month of May in Quintana Roo.

Oscar Flores-Villela verified the species identification. The skinks (ECO-CH-H 2542–2548) are deposited in the Colegio de la Frontera Sur (ECOSUR), Chetumal, Quintana Roo, Mexico.

Submitted by **VICTOR H. LUJA**, Centro de Investigaciones Biológicas del Noroeste (CIBNOR). Mar Bermejo #195 Colonia Playa Palo de Santa Rita, La Paz, Baja California Sur, 23090, México; e-mail: lujastro@yahoo.com.

OPHIODES STRIATUS (Glass Snake). **REPRODUCTION.** Few ecological data exist on the South American anguid *Ophiodes striatus* (Borges-Martins 1998. Taxonomic Review and Phylogenetic Systematics of the Genus *Ophiodes* Wagler, 1828. Ph.D. dissertation, Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil. 239 pp.), and data on reproduction are lacking. Hence, we provide data on clutch size and reproductive mode for *O. striatus* from southwestern Brazil.

At 1800 h on 23 October 2003, an adult (186 mm SVL) female *O. striatus* was collected on the campus of the Universidade Federal de Ouro Preto, Ouro Preto, Minas Gerais (20°23'S, 43°30'W; datum: WGS 84; elev. 1350 m). This area has an old bauxite mine, is currently the focus of much human activity, and has vegetation composed predominantly of exotic species as *Pinus sylvestris* and *Eucalyptus* sp. Mean annual rainfall is 2000 mm. The female *O. striatus* was in the late stages of gestation and contained 14 near-parturition, unshelled embryos (Fig. 1). Hemipenal eversion of the embryos revealed that all were males. The embryos were 46 ± 2.8 mm SVL (0.644 ± 0.02 g). This record confirms the viviparity postulated for the genus *Ophiodes* (see Leitão 1973. Ihéringia,

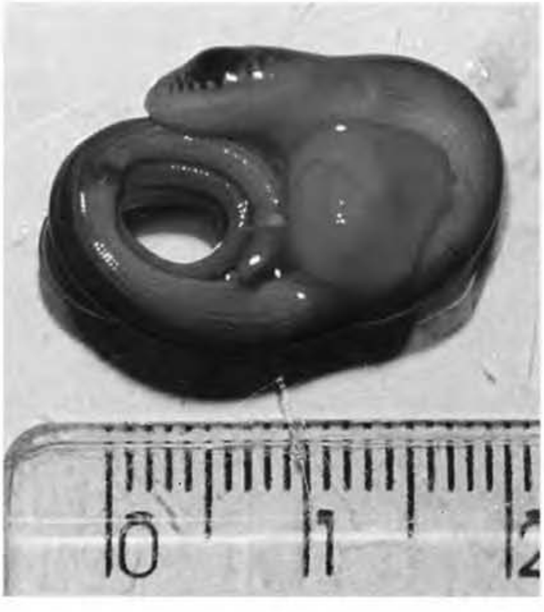

FIG. 1. Late-term embryo of *Ophiodes striatus*, removed from an adult female collected in Minas Gerais, southwestern Brazil.

Sér. Zool., Porto Alegre 42:34–39).

The female *O. striatus* (LZVUFOP 428S) and the embryos (LZVUFOP 432S) were deposited in the herpetological collection at Laboratório de Zoologia dos Vertebrados da Universidade Federal de Ouro Preto.

Submitted by **PEDRO H. BERNARDO** (e-mail: bernardoph@gmail.com) and **MARIA RITA S. PIRES,** Departamento de Ciências Biológicas, ICEB, Universidade Federal de Ouro Preto, 35400-000, Ouro Preto – MG, Brazil.

OPHISAURUS ATTENUATUS LONGICAUDUS (Eastern Slender Glass Lizard). **REPRODUCTION**. Data regarding reproduction in *Ophisaurus attenuatus* has been obtained mostly from individuals in captivity, whereas field data on reproduction is extremely sparse (Blair 1961. Southwest. Nat. 6:201; Mount 1975. The Reptiles and Amphibians of Alabama. University of Alabama Press, Tuscaloosa, Alabama. 347 pp.; Trauth 1984. Southwest. Nat. 29:271–275; Fitch 1989. Occ. Pap. Mus. Nat. Hist. Univ. Kansas 125:1–50; Gerald 2005. Herpetol. Rev. 36:181–182). Moreover, although some information on habitat use by *O. a. attenuatus* exists (e.g., Force 1930. Copeia 1930:25–39; Clarke 1956. Trans. Kansas Acad. Sci. 59:213–219; Fitch, *op. cit.*), little is known about habitat use in *O. a. longicaudus*, especially for oviposition. Hence, here we augment the sparse data on reproduction and habitat important for nesting in *O. a. longicaudus* from central Tennessee, USA.

On 28 June 2005, we encountered an adult female *O. a. longicaudus* coiled around five eggs within a depression under a wooden board that was part of a coverboard array located on Arnold Air Force Base, Franklin Co. (35°20'51"N, 86°09'25"W, datum: NAD 83; elev. 335 m). Habitat consisted of an open Loblolly Pine (*Pinus taeda*) stand containing abundant 1-m tall grasses. This observation occurred ca. 10 m from a similar observation of a female glass lizard brooding eight eggs under a similar wood board in the same array of cover objects ca. 1 year earlier (2 July 2004; Gerald, *op. cit.*). While three of the eggs seemed healthy, two appeared non-viable because the shells were yellow in color, translucent, and slightly sunken in. The female (ca. 70 cm total length) was individually marked with a Passive Integrative Transponder (PIT) tag and subsequently released next to the nest. On 30 June 2005, the same female was observed coiled around the same clutch of eggs. On 8 July 2005, the female was observed coiled around only two eggs, which appeared healthy, averaging 2.55 cm in length and 1.65 cm in width (the eggs were not manipulated to minimize disturbance). One last observation of the female with the still apparently viable eggs was made on 11 July 2005.

The clutch size matches the smallest reported for *O. a. longicaudus* by Fitch (*op. cit.*) and Mount (*op. cit.*) in Kansas and Alabama, respectively. Reduction in egg number between observations may result from egg consumption by the female (see Fitch, *op. cit.*). The continuation of brooding following PIT tag marking suggests that this degree of handling and mode of marking may have little effect on *Ophisaurus* reproductive behavior. These observations, along with those made by Gerald (*op. cit.*), also suggest that open habitats containing tall grasses may be important for *O. a. longicaudus* reproduction. Additionally, use of cover objects for nesting in two subsequent years may indicate that this method might prove useful to assess reproductive behavior in this species.

We thank Michael Briggs, Jacob Briggs, and Joshua Briggs for assistance in the field.

Submitted by **GARY W. GERALD** (e-mail: geraldgw@muohio.edu), **LISETTE E. TORRES** (e-mail: torresle@muohio.edu), Department of Zoology, Miami University, Oxford, Ohio 45056, USA; **JOHN W. PODARCIS BOCAGEI (Bocage's Wall Lizard). **ABNORMAL SCALATION**. Abnormalities in scalation are common in lizards. Bilateral asymmetries are frequent (Dosselman et al. 1998. Herpetologica 54:434–447), as are supernumerary scales. Factors possibly responsible for such developmental anomalies are inbreeding and environmental stress (Braña and Ji 2000. J. Exp. Zool. 286:422–433; Crnobrnja-Isailovic et al. 2005. Amphibia-Reptilia 26:149–158). Here, we report a case of supernumerary femoral pores in a lacertid from northern Portugal.

During an extensive morphological study of Iberian *Podarcis*, an adult female *P. bocagei* (51.34 mm SVL) with an extra row of femoral pores was collected in Gião, coastal northern Portugal (41°18.777'N, 8°41.498'W, datum WGS 84, elev. 140 m). This locality is in the center of the species' distribution, which occupies areas of Atlantic climate on the northwestern Iberian Peninsula (Galán 2003. *In* Carrascal and Salvador [eds.], Enciclopedia Virtual de los Vertebrados Españoles. MNCN-CSIC, Madrid. http://www.vertebradosibericos.org/). Habitat consisted of agricultural fields separated by traditional granite walls, which the lizards use as refuges and in which they achieve high densities. Accessory rows of femoral pores were noted in both hind limbs (Fig. 1). The accessory pores (left N = 9, right N = 7) were smaller and located parallel, in a central position and posterior to the normal series (left N = 20, right N = 20). No other anomalies were found in this animal, which was measured, photographed and released at its site of capture. Examination of another 37 adults (21 males and 16 females) from the same population and 380 individuals from seven other localities across the species' range failed to reveal extra rows of femoral pores. In all the populations studied, males had significantly more femoral pores than females (t-test: $P < 0.05$ in all cases). Notably, the anomalous female had a particularly high number of pores; 20 was the maximum observed among *P. bocagei* we examined and occurred in only 2.8% of individuals (including but one female from a different locality and 10 males from various sites).

Walker (1980. J. Herpetol. 14:417–418) reported accessory femoral pores in the Collared Lizard, *Crotaphytus collaris*. However, in that case a substantial proportion of the adult population (63.7% of males, 36.3% of females) displayed the anomaly. This result, together with the fact that the population was small and isolated, led the author to invoke inbreeding rather than environmental stress to explain the phenomenon. In our case, the population is completely connected to others, and recent studies at this

FIG. 1. Female specimen of *Podarcis bocagei* from Gião, NW Portugal. The white arrows on each side delimit the additional row of femoral pores.

site have revealed no evidence of decreases in genetic diversity (Pinho et al. 2003. Biochem. Genet. 41:343–359; Pinho et al. 2006. Mol. Phylogenet. Evol. 38:266–273). The anomalous individual may simply be a local variant, but it may also be linked to unrecognized developmental stress as pesticides are commonly used to grow corn locally (pers. obs.). Other cases of supernumerary femoral pores have been reported among iguanians (e.g., *Sauromalus obesus*: Tanner and Avery 1964. Herpetologica 20:38–42), but to our knowledge, this is the first such report in lacertids.

PRISTIDATYLUS SCAPULATUS (NCN). **BODY TEMPERATURE.** *Pristidactylus scapulatus* inhabits the east slope of the Andean Cordillera from north of San Juan in San Guillermo Provincial Reserve to Chubut Province (Cei 1986. Museo Regionale di Scienze Naturali Torino. Monografie IV. Torino, Italia. 527 pp.). It has an ambiguous conservation status; it is defined as a species for which "insufficient knowledge" exists (Lavilla et al. 2000. Categorización de los Anfibios y Reptiles de la República Argentina. Asoc. Herpetol. Arg., 97 pp.). No data currently exist on the thermal biology of any of the six species of *Pristidactylus* in Argentina. Hence, here we present preliminary data on *P. scapulatus* thermal ecology.

In December 2004 and February 2005, we conducted field work in the Parque Nacional San Guillermo, Departamento Iglesia, Provincia de San Juan (29°15'S, 69°29'W, datum: WGS 84; elev. 3400 m), located in the Puna Phytogeographic Province. *Stipa speciosa* var. *breviglumis, Lyciun chanar,* and *Adesmia* spp. dominate the largely Andean flora (Cabrera and Willink 1980. Biogeografía de América Latina. Washington, D.C. 109 pp.). Here, we present data based on 10 different *P. scapulatus* observed between 0930 and 1900 h on three different days, nine of which were captured. To collect these data, we revisited a randomized selection of bushes and low rocks across the study site. Each individual was captured by hand, and its SVL was measured to the nearest 0.05 mm. For each capture, cloacal (T_c), substrate (T_s), and air (T_a) temperatures were measured to nearest 0.1°C with a rapid-reading Miller-Weber thermometer. We took T_s at the exact point of observation and T_a 1 cm above the substrate, both immediately following capture. We also recorded microhabitat type for each capture. Following processing, animals were released at the point of capture.

Mean SVL of males was 105.4 mm (SD = 5.54, range: 96–110, N = 5) and mean SVL of females was 83.5 mm (SD = 10.27, range: 70–95, N = 4). Mean body temperature of the nine *Pristidactylus scapulatus* was 27.0°C (SD = 1.8, range: 24.0–29.5°C). Mean air temperature was 26.6°C (SD = 5.6, range: 18.0–33.0°C). Mean substrate temperature was 32.4°C (SD = 8.9, range: 19–42). Body size was unrelated to T_c (Spearman Rank Correlation: $r_s = 0.17$, $P = 0.64$). Cloacal temperature and each of T_s and T_a were correlated (Spearman Rank Correlation: $r_s = 0.80$, $P = 0.008$; $r_s = 0.85$, $P = 0.002$, respectively).

At this site, *P. scapulatus* remained active 4 h per day (1000–1300 h, with maximum activity at 1100–1200 h [64% of observations]). Of the 10 animals we found, nine were under *Lyciun chanar* shrubs and one on a *L. chanar* eating its fruits. Of captured animals, 70% attempted to escape into burrows beneath *L. chanar* shrubs; the remaining 30% did not display escape behavior.

Pristidactylus scapulatus has field body temperatures similar to *P. volcanensis* but higher than *P. torcuatus* and *P. valeriae* (Labra and Vidal 2003. *In* Bozinivic [ed.], Fisiología Ecológica y Evolutiva, pp. 207–224. Univ. Católica de Chile, Santiago, Chile). Despite the small sample size, the high correlation coefficient among T_c, T_s, and T_a suggests that *P. scapulatus* is a thermoconformer. This species may maintain relatively low temperatures by restricting the activity interval and remaining in the shade of *L. chanar* shrubs.

SCELOPORUS OCCIDENTALIS (Western Fence Lizard). **CAUDAL MOVEMENT**. Caudal movements are commonly employed by squamates and serve several purposes. Caudal luring, the use of tail movement to attract prey, is common in snakes (Heatwole and Davidson 1976. Herpetologica 32:332–336) but rare among lizards (Pernetta et al. 2005. Herpetol. Rev. 36:320–321). However, tail autotomy, common in lizards, is typically followed by caudal movements that serve to distract potential predators and aid in escape (Arnold 1988. *In* Gans and Huey [eds.], Biology of the Reptilia, pp. 236–273. Alan R. Liss, Inc., New York). Additionally, in lizards, tail lashing has been observed in *Anolis* during male-male agonistic interactions (Ortiz and Jenssen 1982. Z.

Tierpsychol. 60:227–238). Here I report caudal movements in *Sceloporus occidentalis* immediately preceding prey capture that might serve to attract or distract prey.

At 0845 h on 13 April 2006, I observed an adult (ca. 7.5 cm SVL) male *S. occidentalis* basking on a rock ca. 15 cm off of the ground at the Santa Barbara Zoological Gardens, Santa Barbara Co., California, USA (34°25'13"N, 119°39'57"W, datum: WGS 84; elev. 9.5 m). After ca. 5 min of observation, the lizard caught sight of an insect crawling through the grass and immediately moved onto the ground to within 10 cm from the insect. The lizard promptly vibrated its tail rapidly from side to side, in a display similar to defensive behaviors of many snake species, while keeping the rest of its body motionless and watching the insect. This behavior lasted for ca. 3 seconds, after which the lizard lunged at and captured the insect, immediately ceasing tail movements. After the prey was consumed, the lizard returned to the rock where it remained for the rest of the observation interval (ca. 10 min). No further caudal movements were observed.

As I only observed one individual, tail movements are unlikely to be linked to agonistic behavior. Moreover, the behavior being observed only immediately preceding prey consumption implies a link to predation. It might be coincidental that tail movements preceded prey consumption, but other aspects of the episode suggest either caudal luring or distraction. I did not see the insect moving towards the lizard's tail, as might be expected with caudal luring, but while moving its tail, the lizard's body remained motionless while its gaze was fixed on the insect. To my knowledge, this is the first account of potential caudal luring or distraction of prey in *S. occidentalis*.

I thank Paul Hampton for reviewing an earlier version of this manuscript.

TROPIDURIDAE (Tropidurid Lizards). **DEATH-FEIGNING.** Death-feigning, also called tonic immobility or thanatosis, is an innate, anti-predator behavior that arose independently in several animal lineages, including coleopteran insects (e.g., Acheampong and Mitchell 1997. Entomol. Exp. Appl. 82:83–89; Miyatake 2001. J. Insect Behav. 14:421–432), amphibians (e.g., Gargaglioni et al. 2001. Physiol. Behav. 72:297–303; McCallum et al. 2003. Herpetol. Rev. 34:54–55), snakes (e.g., Burghardt and Greene 1988. Anim. Behav. 36:1842–1844; Rugiero 1999. Amphibia-Reptilia 20:438–440), birds (e.g., Rovee-Collier et al. 1993. Physiol. Behav. 53:353–359; Sargeant and Eberhardt 1975. Am. Midl. Nat. 94:108–119), and mammals (e.g., Leite-Panissi et al. 2003. Brain Res. Bull. 60:167–178). In the actinopterygian fishes *Mycteroperca acutirostris* (Serranidae) and *Haplochromis livingstoni* (Cichlidae) death-feigning is also a hunting behavior (Gibran 2004. Copeia 2004:403–405; McKaye 1981. Environ. Biol. Fish. 6:361–365). In squamates, death-feigning is a widespread defensive tactic that is described from several different families, such as Anelytropsidae (Torres-Cervantes et al. 2004. Herpetol. Rev. 35:384), Crotaphytidae (Gluesing 1983. Copeia 1983:835–837), and Scincidae (Langkilde et al. 2003. Herpetol. J. 13:141–148). Among tropidurid lizards, this behavior has been observed in *Liolaemus lutzae* (Rocha 1993. Ciênc. Cult. 45:116–122) and *Eurolophosaurus nanuzae* (Galdino and Pereira 2002. Herpetol. Rev. 33:54) and *E. divaricatus* (Gomes et al. 2004; Kohlsdorf et al. 2004. Herpetol. Rev. 35:390–391), formerly *Tropidurus nanuzae* and *T. divaricatus* (Frost et al. 2001. Mol. Phylo. Evol. 21:352–371). Herein we augment available data on death-feigning in tropidurids with a brief description of this behavior in *Tropidurus torquatus* and *T. hispidus* and anecdotal records for several other species in the family.

On the morning of 21 April 2002, we observed a death-feigning display by a juvenile (35 mm SVL, 58 mm tail) *T. torquatus* following its hand capture in the urban area of Belo Horizonte, State of Minas Gerais, southeastern Brazil (19°45'S, 43°54'W; elev. 858 m). Upon capture, this individual became immobile, remaining motionless during the handling interval (about 30 s). The death-feigning posture persisted even after the animal was gently placed upside down on the ground (Fig.1A). After 1–2 min it righted itself and ran off. On 4 January 2005, an adult male *T. torquatus* (not measured) was captured by hand in a forested area of the Parque Nacional do Caparaó, municipality of Alto Caparaó, State of Minas Gerais (20°25'S, 41°50'W; elev. 1295 m). Similar to the first example, this individual became immobile upon capture, lying dorsally, extended its limbs upwards and closed its eyelids, remaining motionless during manipulation. The behavior persisted after we placed the animal upside down on the ground. After more than 1 min, it recovered and fled rapidly.

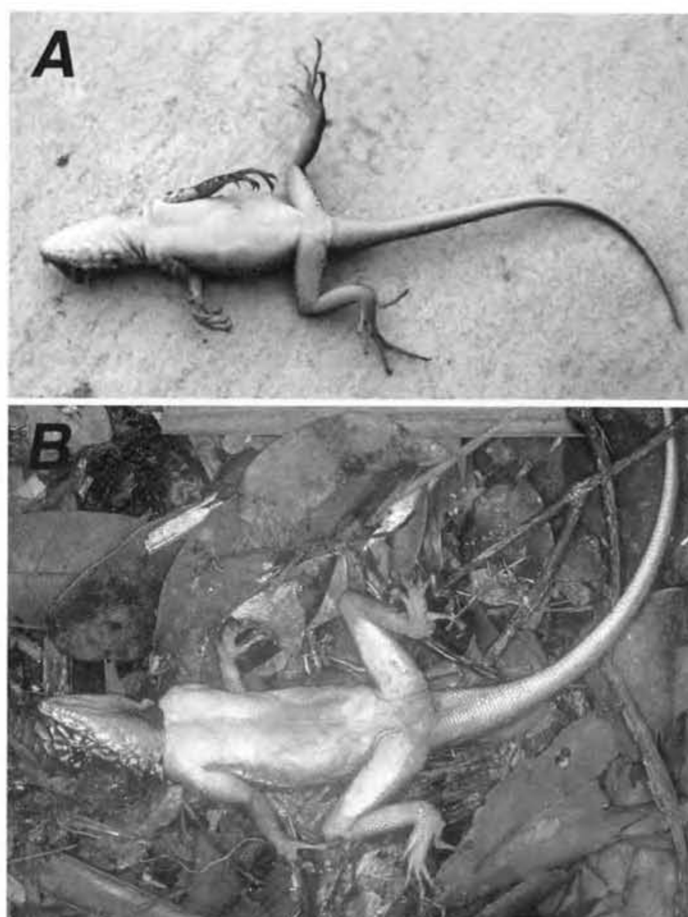

FIG. 1. Death feigning posture in (A) a juvenile *Tropidurus torquatus* from southeastern Brazil and in (B) an adult *Plica plica* from northern Brazil.

On the morning of 20 March 2005, we also observed death-feigning in an adult male *T. hispidus* (12.3 mm SVL, 14.9 mm tail, partly regenerated) following lace capture. The lizard was captured with a small lace mounted with 1 m of dental floss moored to a 1.5 m-length bamboo stick. The capture was made in the urban area of the municipality of Mucugê, State of Bahia, northeastern Brazil (13°00'S, 41°22'W; elev. 986 m; JC field number 1247). This animal's behavior was almost identical to those described above. It remained motionless for more than 1 min after release, then it ran to a rock crevice. On 15 March 2005 an adult male *T. hispidus* (not measured) that, surprisingly, was active at night (because of the presence of internal lights in the room) was captured by hand inside the headquarters building in Parque Municipal Sempre Viva, municipality of Mucugê (12°59'S, 41°20'W; elev. 967 m). After biting a thumb of JC and trying to escape by wriggling its body, it became quiescent. It persisted in this state for more than 1 min. As in the other cases, this individual recovered upon release and ran to a fissure in the house wall.

MTR has also observed death-feigning in many other tropidurids, including *Eurolophosaurus amathites*, *Plica plica* (Fig. 1B), *P. umbra*, *Strobilurus torquatus*, *Tropidurus cocorobensis*, *T. hygomy*, *T. itambere*, and *Uranoscodon superciliosum*. In all cases, the animals displayed a similar pattern of behavior and posture.

Death-feigning has not been recorded previously in *Tropidurus hispidus* (and *T. psamonastes*), even after extensive manipulation (Gomes et al. 2004. Amphibia-Reptilia 25:321–325). The similarity in this behavior among individuals of different species documented by our observations, and its widespread occurrence in the family lead us to conclude that death-feigning is a primitive characteristic in tropidurids, a conclusion also reached by Gomes et al., (*op. cit.*).

TROPIDURUS ETHERIDGEI (NCN). **COURTSHIP**. Courtship in lizards involves many elaborate displays that are better known in iguanians and that are similar between species (Carpenter and Fergusson 1977. *In* Gans and Tinkle [eds.], Biology of the Reptilia: Volume 7. Ecology and Behaviour A, pp. 335–554. Academic Press, Orlando, Florida). Here, we report previously undescribed courtship in *Tropidurus etheridgei*.

Observations were made at 1715 h on 15 October 2003 (rainy season) in a rocky area near the municipality of Corumbá, Mato Grosso do Sul State, Brazil (19°10'49"S, 57°32'17.2"W, datum: WGS84; elev. 117 m). Courtship behavior took place on a rocky substrate near some terrestrial bromeliads (*Bromelia balansae*). The male (ca. 80 mm SVL), who displayed a bright blue dorsal coloration and red ventrolaterally and in the throat region, approached the female (ca. 60 mm SVL) with rapid series of head bobs for 1 min and circled her. The female raised up on four legs, arched her back, and presented her back to the male while raising her tail. The female slowly walked away from the male, who continue to pursue her for the next 10 min; over this period of time, he managed to bite the neck of the female twice and the base of her tail once. We did not observe copulation attempts.

Behavioral aspects of this courtship are quite similar to those described for other *Tropidurus* (Carpenter 1997. Herpetologica 33:285–289), except that they lack the swishing the tail from side to side and dewlap displays. Based on Carpenter (*op. cit.*), the female posture we recorded is a typical rejection posture showed by iguanids.

ÁVILA,** Programa de Pós-Graduação em Biologia Geral e Aplicada, Departamento de Parasitologia, Instituto de Biociências, UNESP, Distrito de Rubião Jr., s/n°, CEP 18618-000, Botucatu, SP, Brazil (e-mail: robsonavila@gmail.com); and **LILIAN R. CUNHA-AVELLAR** (e-mail: liliancapelo@gmail.com).

TROPIDURUS ETHERIDGEI (Ututo). **ENDOPARASITES**. *Tropidurus etheridgei* occurs in Argentina, Bolivia, Brazil, and Paraguay. In Argentina, the species is distributed largely in the Chacoan region (Cei 1993. Reptiles del Noroeste, Nordeste y Este de la Argentina. Monogr. XIV. Mus. Reg. Sci. Nat. Torino, Italy. 949 pp.). The purpose of this note is to report *Physaloptera* sp. (Nematoda) in a population of *T. etheridgei* from Argentina.

Four *T. etheridgei* (mean SVL = 92 mm; range: 80–102 mm) from the herpetology collection of the Universidad Nacional del Nordeste (UNNEC 07916-07919), Corrientes, Argentina, were examined for helminths. All specimens are from Ingeniero Juárez, Formosa Province (23°54'S, 61°51'W, datum: WGS 84; elev. 57 m). The esophagus, stomach, small and large intestines were opened and examined under a dissecting microscope. The body cavity was also searched. One, four, and seven *Physaloptera* sp. were found in the stomachs of each of three of the *T. etheridgei*. In Argentina, *Physaloptera* sp. is known for *T. etheridgei* from Salta Province (Cruz et al. 1998. Herpetol. Nat. Hist. 6:23–31). Nematode infection frequency in the *T. etheridgei* from Ingeniero Juarez (75%) was higher than in *T. etheridgei* from Salta Province (64.5%). Also *Physaloptera* sp. have been found in others species of lizards from Argentina: *Leiosaurus belli* from Río Negro Province, *L. catamarcensis* from La Rioja Province, *Liolaemus neuquensis* from Neuquén Province (Goldberg et al. 2004. Comp. Parasitol. 2:208–214) and *Liolaemus quilmes*, *L. ornatus*, and *L. alticolor* from northwestern Argentina (Ramallo and Díaz 1998. Bol. Chil. Parasitol. 53:19–22). Ingeniero Juárez, Formosa, represents a new locality record for *Physaloptera* sp. in *T. etheridgei*.

We thank M. Hamman, B. Oscherov, B. Álvarez, and A. Hernando for advice on this work.

Submitted by **VICTOR ZARACHO** (e-mail: victorza@exa.unne.edu.ar) and **MATIAS LAMAS** (e-mail: lamasmatias@yahoo.com.ar), Laboratorio de Herpetología, Facultad de Ciencias Exactas y Naturales y Agrimensura, Universidad Nacional del Nordeste, Avenida Libertad 5470, (3400) Corrientes, Argentina.

TROPIDURUS HISPIDUS (Thornytail Lizard). **SAUROPHAGY**. Saurophagy is often opportunistic in lizards, involving either consumption of heterospecifics (Kiefer 1998. Herpetol. Rev. 29:41) or conspecifics (Kiefer and Sazima 2002. Herpetol Rev. 33:136; Vrcbradic and Rocha 1996. Herpetol Rev. 27:201–202). This behavior has been documented in some tropidurids (Avila and Belver 2000. Herpetol. Rev. 31:174; Avila and Morando 2002. Herpetol. Rev. 33:52; Galdino and Van Sluys 2004. Herpetol Rev. 35:173) but is undocumented in *Tropidurus hispidus*, a common diurnal species found in the Guianan Shield (Gorzula and Señaris 1998. Contribution to the Herpetofauna of the Venezuelan Guayana I. A Data Base. Scientia Guaianae No. 8. 269 pp.; Vitt et al. 1996. J. Trop. Ecol. 12:81–101). *Tropidurus hispidus* is sympatric with the nocturnal gekkonid *Hemidactylus palaichthus*; these two species can be found in syntopy but are largely segregated by activity period. Agonistic interaction between these two species has not previously been recorded. Hence, we document a case of attempted predation by *T. hispidus* on *H. palaichthus*.

During a visit to Maripa (town) in the lower basin of the Caura River, northeastern state of Bolívar, Venezuela (07°23'26"N, 65°10'56"W, La Canoa; elev. ca. 70 m), we found *T. hispidus* and *H. palaichthus* syntopic and both very common. At 0800 h on 5 October 2005, we observed an adult (estimated SVL 90 mm) *T. hispidus* persistently pursue on the floor of a rural house an adult (56 mm SVL) *H. palaichthus*, repeatedly biting at the gecko until it was captured. Upon perceiving the presence of FR, the *T. hispidus* immediately released its prey and quickly retreated to a hiding place among some tables. We collected the *H. palaichthus*, which was alive but severely wounded. Examination revealed that its tail had been lost, based on the condition of the scarred stump probably several days earlier. A large piece of dorsal skin (4.2 × 9.3 mm) was missing as a result of the *Tropidurus* bite (Fig. 1). On its venter near the inguinal region, an old scar was presemt that was similar to the bite on its back in size and shape.

While we examined the wounds of the gecko, we observed that the *T. hispidus* had emerged from its hiding place, ca. 5 m away, apparently searching for its prey. We released the gecko, observing from a prudent distance. Three minutes later, the *T. hispidus* moved cautiously in the direction of the gecko and when within one meter it ran quickly to the *H. palaichthus*, grabbing it by the head and swallowing it almost to midbody before returning to its retreat site to continue ingestion. We then attempted to capture both the predator and its prey, but the *Tropidurus* again released the gecko, which, surprisingly, was still alive. The *T. hispidus* evaded capture and the *H. palaichthus* was released after its photograph was taken.

A second *H. palaichthus* (MHNLS 17485) collected the day before these observations also had an old scar on its left shoulder very similar to the injury caused by the *T. hispidus* on the gecko noted previously. These observations led us to believe that attacks on *H. palaichthus* by *T. hispidus* at this locality might be more common than suspected and that the scars observed on the geckos reveal some capacity to survive these attacks.

Previous studies have shown that *T. hispidus* is insectivorous (León et al. 1970. Bol. Soc. Biol. Concepción 42:349–354; Vitt et al., *op. cit.*), although in one study, a single anuran prey item was recovered, representing the only vertebrate recorded in its diet (Vitt et al., *op cit.*). Collectively, these data lead us to believe that saurophagy by *T. hispidus* is opportunistic.

Fig. 1. The gecko, *Hemidactylus palaichthus*, showing dorsal skin trauma as the results of a *Tropidurus hispidus* bite.

J. Celsa Señaris verified the species identities of the lizards. Voucher material is deposited in the Museo de Historia Natural La Salle (MHNLS), under numbers 17482–17483 (*T. hispidus*) and 17484–17485 (*H. palaichthus*). We thank Aaron Bauer and Marc Hayes for comments and corrections to a preliminary version of this note.

TROPIDURUS TORQUATUS (Brown Lizard). **ENDOPARASITES**. *Tropidurus torquatus* is a common lizard in Corrientes and Misiones provinces, Argentina (Cei 1993. Reptiles del Noroeste, Nordeste y Este de la Argentina. Monogr. XIV. Mus. Reg. Sci. Nat. Torino, Italy. 949 pp.). Here we report on the presence of *Parapharingodon* sp. (Nematoda) and larvae (cystacanths) of spiny-headed worms (Acanthocephala) in *T. torquatus* from northern Argentina.

We examined six *T. torquatus* (two juveniles, mean SVL = 51 mm, and four adults, mean SVL = 95 mm; range: 56–103 mm) from Corrientes (city), Corrientes Province (27°28'01"S, 58°47'00"W, datum: WGS 84; elev. 65 m) in the herpetological collection of Universidad Nacional del Nordeste (UNNEC): 8082–8084; 8086–8088. The esophagus, stomach, small and large intestines were opened and searched for helminths under a dissecting microscope. The body cavity was also searched. A total of 11 *Parapharingodon* sp. were found in the large intestines of four adults (numbers observed in each of the four were 1, 2, 3, and 5). We also found two acanthocephalan cystacanths in the stomach wall of one of the juveniles.

To date, previous reports of *Parapharingodon* sp. in *T. torquatus* have been documented for different localities from Brazil: Salva-

dor and Canudos (Bahia), Cachimbo (Pará), Rio de Janeiro and Arraial do Cabo (Rio de Janeiro), Salobra (Mato Grosso do Sul), Mogeiro, Lagoa do Remígio, Umbeseiro and Joao Pessoa (Paraíba), Currais Novos, Ceará Mirin (Rio Grande do Norte), Garanhuns (Pernambuco) (Vicente et al. 1993. Rev. Brasiliera Zool. 10:19–168). Cystacanths of the acanthocephalan *Echinorhynchus* sp. have been found previously in Brazilian populations of this lizard (Vicente 1978. Atas Soc. Biol. Rio Janeiro 19:71–78). These findings represent the first record of *Parapharingodon* sp. and acanthocephalan cystacanths in *T. torquatus* from Argentina.

We thank M. Hamman, B. Oscherov, B. Álvarez, and A. Hernando for their advice.

Submitted by **MATIAS LAMAS** (e-mail: lamasmatias@yahoo.com.ar) and **VICTOR ZARACHO** (e-mail: victorza@exa.unne.edu.ar), Laboratorio de Herpetología, Facultad de Ciencias Exactas y Naturales y Agrimensura, Universidad Nacional del Nordeste, Av. Libertad 5470, (3400) Corrientes, Argentina.

TROPIDURUS TORQUATUS (Brazilian Collared Lizard). **MORTALITY**. Humans produce innocuous-appearing artifacts that can negatively impact wild animal populations. The effects of some of these artifacts are well known (e.g., marine turtles ingesting plastic bags; Tomas et al. 2002. Mar. Pol. Bull. 44:211–216), but the effects of others remain undocumented. Hence, we document a case of accidental mortality apparently caused by such an artifact in *Tropidurus torquatus* from southeastern Brazil.

On 10 August 2000, we found a recently dead subadult male *T. torquatus* (53.7 mm SVL, 78.3 mm tail) trapped in a small piece of plastic spiral (38 mm length × 12 mm internal diameter). The animal was found on a granite outcrop near an Atlantic forest remnant located at the southern limit of the Universidade Federal do Espírito Santo, Vitória, Estado do Espírito Santo (20°16'41.3"S, 40°18'23.9"W, datum: SAD 69 Corrego Alegre; elev. 17 m).

Such plastic spirals are heavily used around the campus to bind xerox copies and class reports. Many end up broken and thrown away to be later inadvertently gathered by the gardeners that collect leaves, vegetation litter, and cut grass. These materials are used as unprocessed fertilizer or to protect exposed soil. Non-biodegradable material tends to become exposed within a few months after wet season processing decomposes organic matter and rains wash away most of the debris of smaller size. This allows lightweight, human-made, degradation-resistant material to be dispersed by wind across bare ground or rock, which is the typical habitat of this lizard (Fredericksen et al. 2003. Trop. Ecol. 44:183–194). Our observation reinforces concerns regarding the impacts of poorly degradable human-made artifacts.

The *T. torquatus* specimen (MBML 1746) was deposited in the herpetological collection of the Museu de Biologia Melo Leitão, Santa Tereza, Espírito Santo, Brazil.

Submitted by **JEAN-CHRISTOPHE JOYEUX** (e-mail: joyeux@npd.ufes.br) and **JOÃO LUIZ GASPARINI**, Departamento de Ecologia e Recursos Naturais, Universidade Federal do Espírito Santo, Av. Fernando Ferrari, 514, Goiabeiras, 29075-910 Vitória, ES, Brazil.

TROPIDURUS TORQUATUS (Collared Lizard, Calango). **PREY.** Lizards of the widely distributed South American genus *Tropidurus* (Rodrigues 1987. Arq. Zool., São Paulo 31:105–230) are sedentary foragers that feed predominantly on arthropods (Van Sluys 1993. J. Herpetol. 27:347–351). However, they can also prey on other lizards (e.g., Galdino and Van Sluys 2004. Herpetol. Rev. 35:173; Kiefer 1998. Herpetol. Rev. 29:41; Kokubum and Lemos 2004. Herpetol. Rev. 35:270–271; Teixeira and Giovanelli 1999. Rev. Brasil. Biol. 59:11–18), including conspecifics (e.g., Alvarez et al. 1985. Hist. Nat. 5:281–288; Dias and Rocha 2004. Herpetol. Rev. 35:398–399; Kiefer and Sazima 2002. Herpetol. Rev. 33:136). Here we record three cases of predation on vertebrates (two lizards and a treefrog) and one case of cannibalism from coastal populations of *Tropidurus torquatus*.

Lizards were captured during a study carried out in "restinga" habitats in the States of Rio de Janeiro, Espírito Santo, and Bahia (16°39'–23°05'S, 39°05'–43°30'W; datum: WGS 84; elev. 2–12 m) from November 1999 to March 2000 and dissected for stomach content analysis. We found a partially digested juvenile (ca. 33.0 mm SVL) *T. torquatus* lacking its midbody and right posterior limb in an adult male (60 mm SVL) from Guriri restinga, State of Espírito Santo, in November 1999.

We also recorded predation on other vertebrates in Jurubatiba (January 2000) and Maricá (February 2000) restingas, both in the State of Rio de Janeiro, by adult males of *T. torquatus*. In Jurubatiba, one male (79 mm SVL) had consumed a juvenile (ca. 29.7 mm SVL) *Mabuya macrorhyncha*. In Maricá, a male (84.0 mm SVL) had eaten a juvenile (ca. 42.0 mm SVL) *Cnemidophorus littoralis* (only the posterior body and the left hindlimb were undigested), and another male (ca. 74.4 mm SVL) preyed on an adult female *Scinax cuspidatus* (ca. 27.5 mm SVL), which was partially digested. We also found a piece (ca. 37.8 mm) of a tail of an adult *M. macrorhyncha* in the stomach of an adult male *T. torquatus* from Jurubatiba.

Predation by *T. torquatus* on other vertebrates has been previously recorded on conspecifics (Alvarez et al. 1985, *op. cit.*; Dutra 1996. Uso de habitats, tamanho, dieta e locais de desova de *T. torquatus* [Sauria: Tropiduridae] em Abrolhos, BA. Bachelor Thesis, Instituto de Biologia, Universidade Federal de Minas Gerais, Belo Horizonte. 56 pp.) and on the lizards *Mabuya agilis* (Teixeira and Giovanelli, *op. cit.*), *Hemidactylus mabouia* (Araújo 1991. Rev. Bras. Biol. 51:857–865; Teixeira and Giovanelli, *op. cit.*; Galdino and Van Sluys, *op. cit.*), *Gymnodactylus darwinii* (Teixeira and Giovanelli, *op. cit.*), *Cnemidophorus ocellifer* (Kokubum and Lemos, *op. cit.*), and on the treefrog *Scinax cuspidatus* (Araújo, *op. cit.*). Nevertheless, our observations of predation on *M. macrorhyncha* and on the endemic *C. littoralis* (a species threatened with extinction) constitute the first records for these taxa where *T. torquatus* was the predator. All lizards preyed upon by *T. torquatus* were juveniles, and their frequencies of occurrence among the prey sampled were low (< 4%), implying that this feeding behavior is opportunistic.

We thank the CNPq for the grants (No. 146442/1999-7 and 150353/2003-0 to MCK, No 307653/2003-0 and 477981/2003-8 to CFDR, and No 301401/2004-7 to MVS), the FAPERJ (CCS), and partially the PELD / CNPq - Site 5 Restinga de Jurubatiba and the Programa de Pós-Graduação em Ecologia, IB, Unicamp. The permit for collecting lizards was given by IBAMA (process

2001.03486/99.85). Rodrigo V. Marra and Davor Vrcibradic confirmed the identity of *S. cuspidatus* and *M. macrorhyncha*, respectively. Davor Vrcibradic kindly revised the text.

Submitted by **MARA CÍNTIA KIEFER, CARLA DA COSTA SIQUEIRA, MONIQUE VAN SLUYS**, and **CARLOS FREDERICO DUARTE ROCHA**, Departamento de Ecologia, IBRAG, Universidade do Estado do Rio de Janeiro, Rua São Francisco Xavier 524, Maracanã, 20550-019 Rio de Janeiro, RJ, Brazil (e-mail: marackiefer@yahoo.com.br).

SERPENTES

AGKISTRODON CONTORTRIX (Copperhead). **DIET**. On 14 September 2004 at 0800 h, one of us (RDG) witnessed a vehicle strike a Copperhead (*Agkistrodon contortrix*) on a secondary gravel road in Botetourt Co., Virginia, USA (37°40.46'N, 79°49.52'W). The snake was collected and brought to the Department of Biology at Hollins University, where the specimen was dissected as a demonstration for students. The cranial region of the intact female snake (680 mm SVL, 762 mm TL) was the only area showing any trauma. Dissection of the stomach revealed an intact, adult female Eastern Wormsnake (*Carphophis amoenus amoenus*; 215 mm SVL) and an intact Orange-tipped Oakworm Moth (*Anisota senatoria*; a previously unreported food item of *A. contortrix*). Brown (1979. Brimleyana 1:113–124) reported *C. a. amoenus* in the gut contents of juvenile *A. contortrix*, and Palmer and Braswell (1998. Reptiles of North Carolina. University of North Carolina Press) reported *C. a. amoenus* in the gut contents of *A. contortrix* in museum specimens. As this is the third documented account of *C. a. amoenus* in the gut contents of *A. contortrix*, we should consider that *A. contortrix* may forage more fossorially, or that *C. a. amoenus* may spend more time above ground, than previously thought. The *A. contortrix* specimen and its gut contents are deposited in the Department of Biology at Hollins University (HU0151).

Submitted by **RENEE D. GODARD** (e-mail: rgodard@hollins.edu), **C. MORGAN WILSON, CHRISTINA M. ROCK**, Department of Biology, Hollins University, Roanoke, Virginia 24020, USA; and **W. BENJAMIN CASH**, Department of Biology, Maryville College, Maryville, Tennessee 37804, USA.

CROTALUS CATALINENSIS (Santa Catalina Island Rattlesnake). **WINTER ACTIVITY**. Grismer (2002. Amphibians and Reptiles of Baja California, Including Its Pacific Islands and the Islands in the Sea of Cortés. University of California Press, Berkeley, California. 409 pp.) reports an activity period spanning from March through October for *Crotalus catalinensis*. However, during a visit to Santa Catalina Island in the winter season (November–February), we found 28 *C. catalinensis* active on the surface. On both 26 and 27 January 2005 a group of five persons searched for snakes from 1200–1600 h and from 1900–2400 h, although not every person searched this entire time period. Sunset was at approximately 1900 h; thus, a total of eleven person-hours were spent searching during the day and 25 person-hours were spent searching at night. We found four *C. catalinensis* (two males, one female, one undetermined) during the day (0.4 snakes/person-hour), whereas 24 *C. catalinensis* (five males, nine females, ten undetermined) were found at night (1.0 snakes/person-hour). When first encountered, fourteen individuals (including those found during the day) were coiled, while the rest were crawling. One male and a female were found together under a rock, but copulation was not observed. With the aid of an infrared thermometer we observed that snakes' body temperatures ranged from 14.2–30.2°C (18.7°C mean, N = 26), and air temperatures at point of snake encounters ranged from 18.0–28.0°C (21.3°C mean, N = 18).

On the night of 26 January, we attached a bobbin of thread (4 g) to the last third of the body of six snakes (four females and two males), and released them at their respective capture sites. The next morning, several females were found some distance from their capture sites (F1, ca. 630 mm SVL, 21.9 m; F2, ca. 600 mm SVL, 31.8 m; F3, ca. 380 SVL, 16.3 m). Another female (F4, ca. 670 mm SVL) and a male (M1, ca. 700 mm SVL) that were captured under the same rock had moved together around a Palo Verde Tree (*Cercidium microphyllum*) and separated; F4 traveled 22 m and M1's bobbin fell off a short distance from the release site. A second male (M2, ca. 620 mm SVL) only moved 0.5 m. On the morning of 28 January, females F1 and F4 had lost their bobbins at distances of ca. 88 m and 44 m from their last locations, respectively. In general, snake movements were linear, passing under or climbing on vegetation to a height of 0.6 m. Diurnal refugia included cavities beneath rocks, fallen Cardon Cactus (*Pachycereus pringlei*), and thickets of plants. In all cases the snake's body could be seen from above.

Capture rates on these winter nights approximate those I recorded during the 2004 rainy season (July–October), when 30 person-hours yielded 38 rattlesnakes (1.2 snakes/person-hour). These observations indicate that *C. catalinensis* also can be quite active during the winter, especially at night. The behavior and displacements observed here suggest that winter activity of *C. catalinensis* might be related to mating activities.

Suppositions of an activity season limited to March through October might be due to a lack of field work in winter, when northwesterly winds in the Gulf of California result in poor sailing conditions (Roden 1958. Pac. Sci. 12:21–45). My observations of winter activity in *C. catalinensis* are consistent with activity patterns exhibited by the closely related *Crotalus ruber* (Murphy and Crabtree 1985. Acta Zool. Mex. 9:1–16), which can be found dead on the roads of Baja California Sur by mid-February (pers. obs.).

I thank M. Martins, G. Arnaud, J. Navarro, and M. A. Leal for their assistance.

Submitted by **HECTOR AVILA-VILLEGAS**, Dirección de Recursos Bióticos, Instituto del Medio Ambiente del Estado de Aguascalientes, Aguascalientes, México (e-mail: avila_hec@yahoo.com.mx).

CROTALUS CERASTES (Sidewinder). **DIET**. Although *Crotalus cerastes* are known to feed on lizards, sympatric *Sceloporus magister* (Desert Spiny Lizard) have not been reported in their diet (Funk 1965. Herpetologica 21:15–17). On 25 May 2003 at ca. 1200 h a dead *C. cerastes* (ca. 300 mm TL) was found on the side of Nipton Road, Nipton, California,USA, adjacent to Mojave National Preserve. Upon dissection I found a partially digested adult (ca. 152 mm TL) *S. magister* in the specimen's stomach.

Submitted by **DONALD LYMAN, JR.**, Department of Biology and Allied Health, Merrimack College, 315 Turnpike Street, North Andover, Massachusetts 01845, USA (e-mail: donlyman@ix.netcom.com).

CROTALUS MOLOSSUS (Black-tailed Rattlesnake). **BEHAVIOR.** Here we report communal hibernation of *Crotalus molossus* in northern Yavapai Co., Arizona, USA. In Cochise Co., Arizona, *C. molossus* do not appear to aggregate during hibernation, but rather hibernate singly in crevices along rim rocks (Greene 1997. Snakes: The Evolution of Mystery in Nature. University of California Press, Berkeley. 351 pp.). However, Cochise Co. is near the latitudinal median of the range of *C. molossus*, while the Yavapai Co. populations we studied are nearer the northern terminus of its range (Campbell and Lamar 2004. The Venomous Reptiles of the Western Hemisphere. Cornell University Press, Ithaca and London. 774 pp.) and occur at relatively high elevations (1370–1675 m).

We have observed multiple *C. molossus* at 14 hibernacula in desert scrub, chaparral, and woodland communities. We have observed up to eight *C. molossus* simultaneously at a single hibernaculum and marked up to 22 individual *C. molossus* over three years at a single hibernaculum. All hibernacula were located at the base of large bedrock outcrops and ledges (> 2 m) comprised of limestone, granite, or schist, with immediately adjacent boulders and cobbles. Other species of snakes utilizing these hibernacula included Arizona Black Rattlesnake (*C. cerberus*), Black-necked Gartersnake (*Thamnophis cyrtopsis*), Striped Whipsnake (*Masticophis taeniatus*), and Western Lyresnake (*Trimorphodon biscutatus).* High site fidelity has been documented in *C. molossus* at these sites and at Tonto National Monument (Gila and Yavapai counties, Arizona) through radio-telemetry and mark-recapture research (M. Spille, G. Schuett, and E. Nowak, unpubl. data). Our observations demonstrate that *C. molossus* hibernates communally in northern, high elevation portions of its range. To our knowledge, this is the first report of communal hibernacula in *C. molossus*.

Submitted by **MATT SPILLE**, 619 S Granite Street, Prescott, Arizona 86303, USA; and **BRYAN HAMILTON**, Great Basin National Park, Baker, Nevada 89311, USA (e-mail: bryan_hamilton@nps.gov).

CROTALUS SCUTULATUS SCUTULATUS (Mohave Rattlesnake). **ALBINISM**. Albinism has been previously documented in five species of *Crotalus*: *C. adamanteus, C. atrox, C. durissus, C. horridus,* and *C. viridis* (e.g., Hensley 1959. Albinism in North American Amphibians and Reptiles. Publ. Mus. Mich. State Univ. 1:133–159; Klauber 1972. Rattlesnakes. Their Habits, Life Histories, and Influence on Mankind. Univ. California Press, Berkeley, California. 1476 pp.; Dyrkacz 1981. Recent Instances of Albinism in North American Amphibians and Reptiles. SSAR Herpetol. Circ. No. 11. 31 pp.). This is the first record of albinism in *Crotalus scutulatus.*

On 30 May 2000, one of us (BA) collected a small (ca. 600 mm) female albinistic rattlesnake in sparsely vegetated desert, dominated by Creosote Bush (*Larrea tridentata*), in northeastern Kern Co., California, USA (ca. 35°35'N, 117°47'W, ca. 800 m elev.). The specimen's background color was yellowish-white with faint diamond-shaped dorsal blotches that were faintly outlined with a darker hue and bordered posteriorly by single rows of whitish scales. The tail was marked with three gray caudal rings, each being one scale row in width and separated by nearly white rings comprised of three scale rows each. The proximal rattle segment was uniformly pale yellow. The irises were tan and the tongue was pink. The crown of the head was devoid of scales in the frontal and prefrontal areas, except for a few widely separated fragments.

The faintly visible pattern, as well as the general body morphology, collection location, and habitat, were consistent with an identification of *C. scutulatus.* In captivity, this specimen has since produced typical *C. scutulatus* offspring with a normally pigmented male. Digital color images of the specimen have been deposited at the San Diego Natural History Museum (SDSNH-HerpPC 5201–03).

Submitted by **MICHAEL D. CARDWELL**, 341 Aviator Circle, Sacramento, California 95835, USA (e-mail: mikecardwell@comcast.net); and **BRAD ALEXANDER**, P.O. Box 851, Kernville, California 93238, USA.

CROTALUS SCUTULATUS SCUTULATUS (Mohave Rattlesnake). **MORPHOLOGY**. Absence of the rattle has been reported in six species of *Crotalus*: *C. cerastes, C. horridus,* and *C. pricei* (Klauber 1956. Rattlesnakes. Their Habits, Life Histories, and Influence on Mankind. Univ. California Press, Berkeley, California. 1476 pp.), *C. atrox* (Painter et al. 1999. Herpetol. Rev. 30:44; Holycross 2000. Herpetol. Rev. 31:177–178), *C. viridis* (Painter et al., *op. cit.*; Holycross, *op. cit.*), and *C. lepidus* (Christman et al. 2004. Herpetol. Rev. 35:62). Herein we report a mature male *Crotalus scutulatus* (LACM 159667) exhibiting total absence of the external rattle and internal rattle shaker.

The frozen headless carcass (ca. 800 mm SVL, ca. 58 mm tail length) was examined by one of us (MDC) on 8 June 2002, after having been killed in late August 1999 near Adelanto, San Bernardino Co., California, USA (ca. 34°32'52"N, 117°31'18"W, ca. 940 m elev.). Sex was verified by an everted hemipenis. Twenty-five subcaudal scales were present, consistent with the range noted (22–28, mean = 25 ± 0.2 SE) for males (N = 34) in a nearby series of *C. scutulatus* (Cardwell, unpubl. data). The exposed skin at the terminus was sooty black and surrounded by a margin of irregularly sized and shaped scales. Radiographs revealed the absence of the internal rattle shaker. It was determined that previous repeated freezing and thawing of the carcass would likely render a histological examination for scar tissue inconclusive. Digital photographs and radiographs have been deposited in the Natural History Museum of Los Angeles County (LACM-PC 1405–1411).

We thank R. Crombie, S. Goldberg, J. Jarchow, B. Moon, A. Rabatsky, and G. Schuett for advice regarding the possible etiology of this deformity and/or the potential for a conclusive determination.

Submitted by **MICHAEL D. CARDWELL**, 341 Aviator Circle, Sacramento, California 95835, USA (e-mail: mikecardwell@comcast.net); and **JOE BANASHEK**, P.O. Box 235, Adelanto, California 92301, USA .

ELAPHE SPILOIDES (Central Ratsnake) **HABITAT USE.** As forests become more fragmented, the proportion of edge habitat increases. In Ontario and the northeastern United States, *Elaphe spiloides* occurs more frequently in edge habitat than due to chance (Blouin-Demers and Weatherhead 2001. Ecology 82:2882–2896; Durner and Gates 1993. J. Wildl. Manag. 57:812–826), possibly because of an increased number of avian (Paton 1994. Conserv. Biol. 8:17–26) and small mammalian prey (Blouin-Demers and Weatherhead, *op. cit.*) in this habitat type. Edge use by ratsnakes might also reflect their increased ability to thermoregulate in this habitat because of increased sun exposure (Weatherhead and Charland 1985. J. Herpetol. 19:12–19). Here, we report the habitat use and home range size of *E. spiloides* in an agriculturally fragmented forest environment in Clark Co., Illinois, USA.

Six *E. spiloides* were implanted with radio-transmitters (Model SI-2T, Holohil Systems, Ltd., Ontario, Canada) and relocated every 1–2 days between 19 May 2003 and 7 November 2004 (except during hibernation). Ambient (ca. 30 cm above shaded ground) and subject body temperatures were recorded at the time of each relocation. Spatial data was analyzed using ArcView Geographic Information System (GIS, v 3.2) or ArcGIS 8.1 (ESRI, Redlands, California) with the Xtools Extension (DeLaune 2000. Oregon Department of Forestry, Salem, Oregon), Spatial Analyst Extension, and Animal Movement Extension (Hooge and Eichenlaub 2000. Alaska Science Center – Biological Science Office, U.S. Geological Survey, Anchorage, Alaska). Individual locations were plotted using UTM coordinates on Illinois Digital Orthophoto Quadrangle (DOQ) maps imported into ArcView GIS. We calculated the home range size of each individual using the minimum convex polygon method (Jennrich and Turner 1969. J. Theor. Biol. 22:227–237). Habitat types (Table 1) were quantified within home ranges by defining habitat boundaries on the DOQ maps within ArcGIS. Edge habitat (± 15 m of the boundary between forest and any open habitat; following Blouin-Demers and Weatherhead, *op. cit.*), was assigned as a unique habitat type to test for edge preference.

Mean mass (± 1 SE) of the subjects was 654.5 ± 109.0 g, and mean snout–vent length was 119.8 ± 11.3 cm. Mean ambient temperature and snake body temperature during relocations were 23.6 ± 0.3°C and 23.2 ± 0.3°C, respectively. Subject body temperature exceeded ambient temperature during 40.8% of the relocations. Snakes were relocated a total of 417 times over periods ranging from 58 to 428 days, providing 212 sample points for the determination of home range sizes and patterns of habitat use. The mean home range size was 9.65 ± 3.62 ha. Subjects used the seven habitat types non-randomly ($G = 106.50$, df = 6, $P < 0.001$; Table 1). Of the dominant habitat types (i.e., agricultural field, deciduous forest, edge, and grassland/pasture), snakes occupied forest and forest edges more often than would be expected due to chance, and appeared to avoid open habitats ($G = 101.90$, df = 3, $P < 0.001$). Subjects also occupied forest edges more often than forest interiors, despite the fact that the latter comprised a greater proportion of available habitat ($G = 83.92$, df = 1, $P < 0.001$; Table 1).

The mean home range for *E. spiloides* in this study was on the higher end of the distribution of home ranges reported for populations in less fragmented habitats (e.g., Mullin et al. 2000. Herpetol. Rev. 31:20–22), possibly reflecting decreased availability of resources for snakes at our study site. Our subjects were located in edge habitat more often than expected (Table 1), a finding that is consistent with previous studies conducted in the northeastern U.S. (Blouin-Demers and Weatherhead, *op. cit.*; Durner and Gates, *op. cit.*). Our results contrast, however, with a study of ratsnakes in Vermillion Co., Illinois (110 km N of Clark Co., Illinois) in which ratsnakes were associated with forest habitat but were not consistently located in edges (Keller and Heske 2000. J. Herpetol. 34:558–564). In addition to assessing the impacts of anthropogenic habitat fragmentation on other snake species, future studies should explore the effects of edge habitat availability on *E. spiloides* population structure and dynamics.

TABLE 1. Pooled number of observed and expected relocations (based on proportions of habitats within a subject's home range) for six *Elaphe spiloides* radio-tracked in Clark County, Illinois, between 19 May 2003 and 7 November 2004.

Habitat Type	Observed	Expected
Agricultural Field	0	24.8
Deciduous Forest	89	124
Edge	114	60.9
Grasses	8	2.6
Buildings	1	0.1
Residential Yard	0	0.2
Road/Driveway	0	0.2

Robert Szafoni of the Illinois Department of Natural Resources (IDNR) initiated this project, and the IDNR provided funding. Collections were authorized by permit #NH03-0946 (IDNR), and surgical procedures were approved by IACUC protocol #04-007.

MASTIGODRYAS MELANOLOMUS (Salmon-bellied Racer). **ENDOPARASITES.** *Mastigodryas melanolomus* is known on the Atlantic versant from Tamaulipas, Mexico, to western Panama and on the Pacific slope from Nayarit to western Guatemala, Costa Rica, and western and central Panama (Savage 2002. The Amphibians and Reptiles of Costa Rica. A Herpetofauna Between Two Continents Between Two Seas. University of Chicago Press, Chicago, Illinois. xx + 934 pp.). There are, to our knowledge, no published reports of endoparasites from *M. melanolomus.* The purpose of this note is to report one species of Cestoda, two species of Acanthocephala, and one species of Nematoda from *M. melanolomus.*

Seventy-one *M. melanolomus* from Costa Rica (SVL = 680 mm ± 114 SD, range: 422–941 mm) collected 1958–1962, 1964, 1966, 1967, 1971, 1974, 1982, 1983, 1985, from Alajuela Province (LACM 153462, 153475, 153505, 153509); Cartago Province (153416, 153419, 153422, 153424, 153426, 153428,153430–153436, 153439, 153441, 153445, 153460, 153463, 153466, 153469, 153474, 153477, 153478, 153480–153482, 153507,

153512); Guanacaste Province (153420, 153458,153465, 153520); Heredia Province (153453, 153461, 153518); Limón Province (153423, 153427, 153429,153438, 153443, 153446, 153483, 153510, 153511, 153516, 153517); Puntarenas Province (114114, 153418, 153421, 153425, 153442, 153450-153452, 153457, 153476, 153506, 153508, 153523); San José Province (153417, 153437, 153440, 153472, 153473, 153479, 153513, 153514) were examined from the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California. A mid-ventral incision was made in the body wall; organ surfaces and mesenteries in the posterior portion of the body cavity were visually examined for helminths. Found were larval Cestoda (metacestodes in cysts), (prevalence [infected snakes/snakes examined × 100] = 13%; mean intensity [mean number of helminthes per infected lizard ± 1 SD] = 2.0 ± 1.7; range [minimum to maximum number per host] = 1–6; larval Acanthocephala (centrorhyhchid cystacanths) prevalence = 3%; mean intensity: 1.0; range: 1; Acanthocephala (oligacanthorhynchid cystacanths) prevalence = 7%; mean intensity: 3.2 ± 2.2; range: 1–6; Nematoda, larval *Porrocaecum* sp. prevalence = 3%; mean intensity 5.0 ± 5.7; range: 1–9. These were prepared as whole mounts using standard parasitological techniques (Cestoda, Acanthocephala) or cleared in glycerol (Nematoda) and identified. Vouchers were deposited in the United States National Parasite Collection (USNPC) as Cestoda: metacestode larvae (98663); Acanthocephala: Centrorhynchidae (98665); Oligacanthorhynchidae (98666); Nematoda: *Porrocaecum* sp. (98664).

Mastigodryas melanolomus feeds mainly on lizards but may also eat snakes, birds, and small mammals (Savage 2002, *op. cit.)*. The juvenile Cestoda (metacestodes) (Roberts and Janovy 2005. Gerald D. Schmidt & Larry S. Roberts' Foundations of Parasitology. McGraw Hill, Boston, Massachusetts. 702 pp.), juvenile Acanthocephala (centrorhynchs), and larval Nematoda *(Porrocaecum* sp.) probably reached *M. melanolomus* by the ingestion of infected prey items. *Mastigodryas melanolomus* likely functions as a paratenic (transport host) with development to the adult parasite occurring when the snake is eaten by a predator. This is further suggested as adults of *Porrocaecum* are normally found in birds (Anderson 2000. Nematode Parasites of Vertebrates: Their Development and Transmission. CABI Publishing, Wallngford, Oxon U.K. 650 pp.). None of the helminths found in this study was unique to Costa Rica or *M. melanolomus* (Goldberg and Bursey 2004. Carib. J. Sci. 40:62–69). Cestoda metacestode larvae, Acanthocephala centrorhynchid and oligacanthorhynchid cystacanths and Nematoda, *Porrocaecum* sp. in *M. melanolomus* are new host records.

We thank Christine Thacker (LACM) for permission to examine snakes which are part of the CRE collection donated to LACM by Jay M. Savage in 1998.

Submitted by **STEPHEN R. GOLDBERG,** Department of Biology, Whittier College, Whittier, California 90608, USA (e-mail: SGoldberg@whittier.edu); and **CHARLES R. BURSEY,** Pennsylvania State University, Shenango Campus, Department of Biology, Sharon, Pennsylvania 16146, USA.

NERODIA RHOMBIFER (Diamond-backed Watersnake). **FORAGING BEHAVIOR**. On 5 August 2005, we captured an adult male *N. rhombifer* (760 mm SVL, 244 mm tail length) in a shrimp trap that had been set 3 m deep on the bottom of the Atchafalaya River near the town of Butte La Rose in St. Martin Parish, Louisiana, USA. The river had muddy banks and bottom, was near minimum low-stage water flow, had water clarity of about 0.3 m, and lacked submerged vegetation. The snake was in the final stages of drowning when removed from the trap at about 0900 h, and hence probably entered the trap within the preceding hour. The trap was 25 cm in diameter, 76 cm long, and made of 6 mm (mesh size) hardware cloth, with a 4 cm opening in the throat. A partially decomposed long-nosed gar (*Lepisosteus osseus*) was placed in the trap as bait. In addition to the snake and bait, the trap contained about 12 medium-sized river shrimp (*Macrobrachium ohione*) and several small blue catfish (*Ictalurus furcatus*). Maximum foraging depths have not been reported for this species, although it has been observed diving in open water that was at least 3 m deep (Keck, unpubl. data, cited in Gibbons and Dorcas 2004. North American Watersnakes: A Natural History. Norman, Univ. Oklahoma Press). Our trapped specimen demonstrated a foraging depth of at least 3 m, which supports the hypothesis of Mushinsky et al. (1982. Ecology 63:1624–1629) that large watersnakes forage in deep, open water. The snake's stomach was empty. Given the strong preference of *N. rhombifer* for fish prey (Gibbons and Dorcas 2004) and the murky water, we suspect that the snake used chemosensory cues to find the strong-smelling bait fish or the catfish in the trap.

Submitted by **A. JAMES DELAHOUSSAYE**, Louisiana Department of Environmental Quality, Baton Rouge, Louisiana, 70821, USA (e-mail: jim337@centurytel.net); and **BRAD R. MOON**, Department of Biology, University of Louisiana at Lafayette, Lafayette, Louisiana 70504-2451, USA (e-mail: BradMoon@louisiana.edu).

NINIA MACULATA (Spotted Coffee Snake). **ENDOPARASITES.** *Ninia maculata* is known from northeastern Honduras, Nicaragua, Costa Rica, and western Panama (Savage 2002. The Amphibians and Reptiles of Costa Rica. A Herpetofauna Between Two Continents Between Two Seas. University of Chicago Press, Chicago, Illinois. xx + 934 pp.). To our knowledge, there are no published reports of endoparasites from *N. maculata*. The purpose of this note is to report two species of Nematoda from *N. maculata*.

Eleven *N. maculata* from Costa Rica (SVL 222 ± 23 mm SD, range: 178–258 mm) were collected 1962–1964, 1966, 1967 from Cartago Province (LACM 153828) and San José Province (LACM 153826, 153833–153837, 1538430, 153842, 153843, 153851). A mid-ventral incision was made, and the digestive tract was removed. The esophagus, stomach, small and large intestines, and body cavity were examined for endoparasites using a dissecting microscope. Two species of Nematoda were found: mature males and gravid females of *Cosmocercoides variabilis* (infection site: small and large intestines; prevalence [infected snakes/snakes examined × 100] = 45%; mean intensity [mean number of helminths per infected lizard ± 1 SD] = 8.4 ± 9.5; range [minimum to maximum number per host] = 1–24); juveniles of *Cruzia* sp. (infecton site: small and large intestines; prevalence = 18%; mean intensity = 4.5 ± 0.7; range = 4–50). These were cleared in glycerol for

study, then deposited in the United States National Parasite Collection, *Cosmocercoides variabilis* (USNPC 98852) and *Cruzia* sp. (USNPC 98853).

Two species of *Cosmocercoides* occur in the Americas, *C. dukae* and *C. varabilis* (Vanderburgh and Anderson. 1987. Can J. Zool. 65:1650–1661). The major difference between the two species is the number of rosette papillae of the male: *C. dukae* with 12 pairs; *C. variabilis* with 14–20 pairs. We have assigned these individuals to *C. variabilis* because the males possess 14 or 15 pairs of rosette papillae. *Cosmocercoides variabilis* is widely distributed in North America, where it has been reported from Caudata, Anura, Squamata, and Chelonia (Baker 1987. Mem. Univ. Newfoundland Occas. Pap. 11:1–325). Species of *Cruzia* are primarily parasites of mammals but have been reported from several species of amphibians and reptiles (Baker, *op. cit.*). Transmission of *C. variabilis* and species of *Cruzia* is direct and does not involve an intermediate host (Anderson 2000. Nematode Parasites of Vertebrates. Their Development and Transmission. 2nd Ed. CABI Publishing, Oxon, UK. xx + 650 pp.). *Ninia maculata* represents a new host record and Costa Rica is a new locality record for both *C. variabilis* and *Cruzia* sp.

We thank Christine Thacker (LACM) for permission to examine snakes, and Jessica Carlson and Dustin Goto (Whittier College) for assistance with dissections. Specimens of *N. maculata* are part of the CRE collection donated to LACM by Jay M. Savage in 1998.

Submitted by **STEPHEN R. GOLDBERG,** Department of Biology, Whittier College, Whittier, California 90608, USA (e-mail: SGoldberg@whittier.edu); and **CHARLES R. BURSEY,** Pennsylvania State University, Shenango Campus, Department of Biology, Sharon, Pennsylvania 16146, USA.

OPHIOPHAGUS HANNAH (King Cobra). **DIET**. Despite the common assertion that King Cobras primarily eat snakes, or snakes and occasionally varanids (e.g., Evans 1902. J. Bombay Nat. Hist. Soc. 14:409–418; Smith 1943. Fauna of British India: Reptilia and Amphibia, Vol. III, Serpentes. Taylor & Francis, London), few specific records of the diet of *Ophiophagus hannah* exist in the literature. Furthermore, dietary records in this species are geographically clustered, despite the species' broad distribution. Eight of 10 records that I found in which a specific prey item was named are from India. One other record (Craddock 1903. J. Bombay Nat. Hist. Soc. 15:143) is from Malaysia. Wray (1907. J. Fed. Malay States Mus. 64–65) reported on the diet of the King Cobra without naming localities for the specimens; presumably these snakes were also from Malaysia. I found no records of the diet of *O. hannah* in the wild in Thailand.

On 7 February 2005 at 0947 h, I observed a juvenile *O. hannah* (ca. 2 m SVL) beginning to swallow an adult *Rhabdophis nigrocinctus* (ca. 70 cm SVL). I was alerted to the presence of the snakes by their struggle, and when I returned with a camera, the cobra was in the process of ingesting the keelback head-first. I photographed the snakes to confirm their identities (KU Digital Archive, KUDA 001722). Both snakes were on the ground in a clearing around a small pond, about 5 m from the forest edge and 5 m from the pond edge, in dry, evergreen forest at Sakaerat Environmental Research Station, Nakhon Ratchasima Province, northeast Thailand (14°29'43.4"N, 101°55'07.4"E).

I thank A. Bauer, J. G. Hill, and Rudkin Fund of the University of Kansas Natural History Museum and Biodiversity Research Center for assistance.

Submitted by **KYLE HESED**, Division of Herpetology, Natural History Museum and Biodiversity Research Center, 1345 Jayhawk Blvd., University of Kansas, Lawrence, Kansas 66045-7561, USA; e-mail: kyleh@ku.edu.

REGINA RIGIDA (Glossy Crayfish Snake). **MAXIMUM SIZE**. An adult male *Regina rigida* collected 30 March 2005, 10 mi E of Pollock (Grant Parish, Louisiana, USA) measured 830 mm TL. This exceeds the previous record of 797 mm total length (Shoop 1959. Herpetologica 15:160) by 33 mm. The specimen is deposited in the vertebrate collection of Louisiana State University Museum of Zoology (LSUMZ 89683).

Submitted by **THOMAS G. EIMERMACHER, DAMIAN T. GREEN,** and **LUCAS WATKINS**, Department of Biological Sciences, Southeastern Louisiana University, Hammond, Louisiana 70402, USA.

REGINA SEPTEMVITTATA (Queen Snake). **PREDATION.** Reports of arachnids preying on snakes are uncommon (Bayliss 2001. Herpetol. Rev. 32:49; Groves and Groves 1978. Bull. Maryland Herpetol. Soc. 14:44–46; Lazcano et al. 2005. Herpetol. Rev. 36:186; McCormick and Polis 1982. Biol. Rev. 57:29–58; Zippel and Kirkland 1998. Herpetol. Rev. 29:46). Some spiders have been noted to feed on small snakes (Groves and Groves, *op. cit.*; McCormick and Polis, *op. cit.*), and a few species have been found entangled in spiderwebs (e.g. Bayliss, *op. cit.*; Zippel and Kirkland, *op. cit.*). Here, I report the first account of a spider feeding on the carcass of a subadult *Regina septemvittata*.

At 1025 h on 24 May 2003, a deceased *R. septemvittata* (325 mm SVL) was discovered while being eaten by an adult *Dolomedes tenebrosus* in Wilson Co., Tennessee, USA. The spider, an adult female with a ca. 7 cm legspan, was feeding on the snake's flesh ca. 3 cm posterior to the head under a large rock situated on the bank of Fall Creek (ca. 7 m wide). It is unclear if the spider killed the snake or located the carcass and began to consume it. Because both species appear to be abundant and share the same riparian habitats, predation by *D. tenebrosus* on *R. septemvittata* might not be uncommon.

Sun-Basking and Desiccation in Two Frog Species from the Periphery of the Australian Arid Zone

KLAUS HENLE
UFZ- Centre for Environmental Research
Department of Conservation Biology, Permoserstr. 15
D-04318 Leipzig, Germany
e-mail: klaus.henle@ufz.de

Amphibians are well-known for their sensitivity to water loss and relatively few species have developed adaptations that allow them to survive in xeric environments (Duellman and Trueb 1986; Warburg 1997; Zug et al. 2001). Adaptations to xeric environments include a nocturnal lifestyle, typical water-conserving resting postures, aestivation during dry conditions, and dehydration tolerance (Hillman 1980; Kobelt and Linsenmair 1992; Pough et al. 1998). Only a few species have evolved adaptations that allow them to bask in bright sun when not immersed in water (Brattstrom 1979; Buttemer 1990; Christian and Parry 1997; Duellman and Trueb 1986; Stebbins and Cohen 1995). I define sun-basking as sitting exposed to the sun for prolonged periods while access to shade is possible. Sun-basking has the advantage of allowing attainment of an increased body temperature which benefits digestion and growth (Lillywhite et al. 1973), and hence may reduce time to reach sexual maturity and allow attainment of larger body size.

Given the desiccating conditions to which frogs living in semi-arid zones are exposed they should avoid sun-basking. To my knowledge sun-basking in desert frogs has been reported only for young *Bufo debilis* (Seymour 1972). Here I report observations on sun-basking and desiccation in two frog species from the periphery of the arid zone in Australia.

The observations were made incidentally as part of a study of the population and community ecology of reptiles in Kinchega National Park, western New South Wales, Australia (32°28'S, 142°20'E). Kinchega National Park is located at the periphery of the arid zone with an average yearly rainfall of 236 mm that is highly variable between years but evenly spaced across the year (Robertson et al. 1987). Mean annual maximum temperature (1995–2002) ranged between 25.4 and 27.6°C and mean monthly maximum temperature (1992–2002) varied between 14.6 and 39.2°C.

The study area extended ca. 500 m to the north, 200 m to the east, and 500 m to the west of Kinchega Station. It consisted of Black Box (*Eucalyptus largiflorens*) riverine woodland on grey clay soil and the adjacent red sand dunes. Partial flooding of the study sites occurred in 1989, 1990, 1998, and 1999. For more details on the study area see Caughley et al. (1987) and Henle (1990).

The study site was visited every second month from September 1985 to May 1987 and yearly from 1996–2006 in February/March. During each visit, at least eight daytime and eight nocturnal visual searches of 2–3 h duration were made. In addition, temporary ponds and puddles that formed in the vicinity of the study area after heavy local rains were checked for amphibians at least once per visit at night and during the day.

The frog community in the study area consisted of four species: *Limnodynastes tasmaniensis, Neobatrachus* cf. *pictus, Litoria caerulea*, and *Litoria peronii*. A single adult of a fifth species, *Crinia parinsignifera*, was caught in a pitfall trap. All recently metamorphosed *N.* cf. *pictus* (N = approx. 50) and *L. tasmaniensis* (N = 11) were observed at night. Of 106 juvenile *L. caerulea*, eight individuals and the single juvenile *L. peronii* were observed sun-basking in May 1998. No adults of any of the four species were ever observed sun-basking in spite of > 500 *L. tasmaniensis*, > 500 *L. peronii*, > 1000 *L. caerulea*, and > 5000 *N.* cf. *pictus* observed. The difference is highly significant for *L. caerulea* ($\chi^2 = 70; \alpha = 0.00$) and *L. peroni* ($\chi^2 = 500; \alpha = 0.00$). Seymour (1972) and Freed (1980) also observed that recently metamorphosed anurans are more prone to expose themselves to the sun than adult frogs.

All sun-basking juveniles were sitting fully exposed to the sun, either on the ground between herbs (3 *L. caerulea*) or in the axilla of large leafs (1 *L. peronii* and 5 *L. caerulea*). They retained their position for the whole observation period (approximately 10 minutes) and made no effort to seek nearby shade underneath herbs or in the numerous cracks in the soil. At the time of observations there were neither clouds nor wind. It was the hottest part of the day with temperatures reaching 37.7°C (*L. caerulea*) and 29.5°C (*L. peronii*) in the shade 2 m above the ground. For *L. caerulea*, the shade temperature reached the lower limit of the range of the Critical Thermal Maximum determined by Johnson (1970).

Although limited diurnal activity also occurred in adults of all species, diurnal activity invariably occurred in shelter, such as calling from within very dense flooded bushes or from within hollow trees after rain. In addition, *L. caerulea* occasionally was seen active during the day close to artificial water bodies such as toilets or water tanks that were sheltered from the sun.

Three adult *L. caerulea* were found desiccated on dirt tracks in the morning of a sunny day and apparently failed to locate a safe retreat. In all cases, the closest safe retreats were in a distance of ≥ 20 m. These dead frogs were in a resting position with the feet tightly tucked underneath the body and the whole body forming a hemisphere.

Shady retreats are less available for adult frogs due to their larger size. Therefore, they likely have a higher desiccation risk, which probably explains why adult frogs were not observed sun-basking. A difference between juveniles and adults to withstand desiccating conditions has been shown for the African reed frog *Hyperolius nitidulus* (Rödel 2000). Physiological adaptations to winds associated with canopy locations (Buttemer 1990) may explain why sun-basking is more prominent in more arboreal frog families, such as hylids and hyperoliids, and absent in syntopic species of more terrestrial families (McClanahan and Shoemaker 1987; Rödel 2000; this study).

Acknowledgments.—I thank NSW National Parks and Wildlife Service to grant licenses for fieldwork (license number S10935, formerly A478) and for logistic support.

Activity Season, Habitat Use, and Environmental Temperature Selection of the Prairie Racerunner (*Aspidoscelis sexlineata viridis*) at the Northern Limit of its Range

JOSHUA M. KAPFER
Department of Biological Sciences, University of Wisconsin-Milwaukee
Milwaukee, Wisconsin 53211, USA
e-mail: jmkapfer@uwm.edu

and

MICHAEL J. PAUERS
Department of Cell Biology, Neurobiology, and Anatomy
Medical College of Wisconsin, Milwaukee, Wisconsin 53226, USA
e-mail: mjpauers@mcw.edu

Regulation of body temperature is a critical function in the lives of many ectotherms, particularly lizards (Huey and Slatkin 1976; Pianka and Vitt 2003). The cost of thermoregulation in ectotherms comes in the form of tradeoffs with other activities that are important for survival (e.g., feeding or predator avoidance), whereas the benefits include performing at peak metabolic and behavioral capacity (Huey and Slatkin 1976; Pianka and Vitt 2003). Lizards of the genus *Aspidoscelis* (formerly included in *Cnemidophorus*; Reeder et al. 2002) are well known for their precise thermoregulation of high body temperatures (36–42°C), which they achieve by shuttling between thermal sources and sinks (Bowker and Johnson 1980; Fitch 1958; Milstead 1957).

Thermoregulation is considered important to the metabolic and behavioral performance of racerunners (e.g., Fitch 1958; Hardy 1962). Although the thermal ecology of Prairie Racerunners (*Aspidoscelis sexlineata viridis*; previously classified in much of the upper Midwestern United States as the Six-lined Racerunner *A. sexlineata sexlineata*; Conant and Collins 1998) and other *Aspidoscelis* has been studied in other regions of the United States (e.g., Fitch 1958; Hardy 1962; Paulissen 1988; Witz 2001; Wright and Vitt 1993), very little empirical information has been published on this subspecies in the upper Midwest United States (Warner 2000). Because these regions represent the northern distributional limit of *A. s. viridis* (Conant and Collins 1998), studies of active-season duration, habitat use, and environmental temperature selection should yield important insights into the biology of this subspecies.

The duration of the active season and habitat selection by *A. sexlineata* have been reported for several regions of the United States (Fitch 1958; Hardy 1962; Witz 2001). For the upper Midwest, most information on the habitat preferences and seasonal activity of racerunners is summarized in field guides (Harding 1997; Oldfield and Moriarty 1994; Phillips et al. 1999; Vogt 1981). According to these sources, this subspecies prefers open-canopy habitats such as pine barrens, open grasslands, and oak savannas with loose dry soil and sparse ground vegetation. These habitats can experience high environmental temperatures (JMK, pers. observ.). Unfortunately, this information is qualitative, and to our knowledge there have been no attempts to quantitatively characterize the habitats used by *A. s. viridis* in the upper Midwest.

Our study was conducted to obtain quantitative ecological data, which are lacking for *A. s. viridis* in the upper Midwest. First, we determined the length of the activity season and compared our findings to other reports for the subspecies. Second, we quantified habitat use at our study site. Third, we determined whether ground-surface temperatures differed among habitats used by *A. s. viridis*. The second and third points begin to circumscribe the niche of this subspecies, which may need to be managed to insure its long-term survival in this region.

TABLE 1. Type, amount, and observed use of habitats by *Aspidoscelis sexlineata viridis* in Sauk County, Wisconsin, USA.

Habitat Type	Habitat Size (ha)	% of Study Site	Lizard Use (%)
Agriculture	279	33.7	0.0
Open bluffside	48	5.8	2.6
Closed canopy forest (bluff)	298	36.1	0.0
Conifer forest	3	0.4	0.0
Edge habitat (natural/agricultural)	35	4.2	0.0
Hillside with occasional brush/trees	12	1.5	0.0
Residential landscape	25	3.1	0.0
Oak savanna	58	7.0	58.9
Open grassland	45	5.5	38.4
Roadside grass	15	1.9	0.0
Sandblown	6	0.7	0.0
Totals	824	100.0	100.0

The study site was located in southwestern Wisconsin (Sauk County) on 824 ha of land managed by The Nature Conservancy (TNC) in the Lower Wisconsin River Valley. The habitats present included restored sand prairie and oak savanna in the lowlands, and adjacent west-to-south-facing bluffs with exposed limestone outcroppings cleared of overstory vegetation in some areas. Oak savannas had mostly sandy soils with sparsely clumped shrubby vegetation and leaf litter. Oak trees (*Quercus*), occasionally > 6 m in height and ranging from 5–40 m apart, occurred in clumped stands throughout the study site. Understory vegetation in these habitats occurred irregularly and usually consisted of raspberry (*Rubus*) tangles or xerophilous plants near the oak trees. Open grassland and sand prairie habitats also had sandy soils, but little canopy vegetation, and understory vegetation rarely exceeded 100 cm in height. Often, this understory vegetation (*Andropogon*, *Opuntia*, and *Sorghastrum*) was clumped, with intervening areas of open sand. The land bordering the TNC property was dominated by agriculture (row crops or pasture) and residential lawns with ornamental shrubs, or rubble piles near homes in the lowlands. Closed canopy forests, consisting of cedar (*Juniperus*) and oak (*Quercus*), lined the west-to-south-facing bluffs that bordered TNC property. Some of the study site has been managed since the 1970s, with past and ongoing management including native seed application, burning, and eradication of invasive plant species (*Alliaria*, *Juniperus*, and *Robinia*).

Visual surveys for active *A. s. viridis* were conducted from early April until mid-October in 2004 and 2005 and four times in August of 2003. Surveys were conducted at least 3 days each week from approximately 0930–1430 h. Typically only one surveyor (JMK) was present. The surveys were conducted by walking through all habitats at the study site (i.e., not solely in areas with high abundances of *A. s. viridis*). Although all habitats were sampled during each survey, it was not possible to survey all habitat types equally on a given day.

Upon encountering a basking lizard, several parameters were recorded at the position where it was observed. Because these lizards are apt to flee when disturbed, we only recorded data for observations in which it could be determined where the lizard was resting prior to flight. Each location was recorded using a global positioning device (Garmin® GPS III Plus; Olathe, Kansas). Habitat type was characterized in the field and confirmed via geographic information system (GIS) based on an aerial photograph (ArcMap 8.2; Table 1). Microhabitat analyses of the vegetation were also conducted, including the percent of ground cover in a 1-m^2 area centered on each lizard occurrence. We recorded soil type as sand, soil, sand/soil mix, or soil/gravel mix. Tree-canopy cover was measured via a convex densiometer (Ben Meadows, Atlanta, Georgia). We estimated soil-surface temperatures at each lizard local-

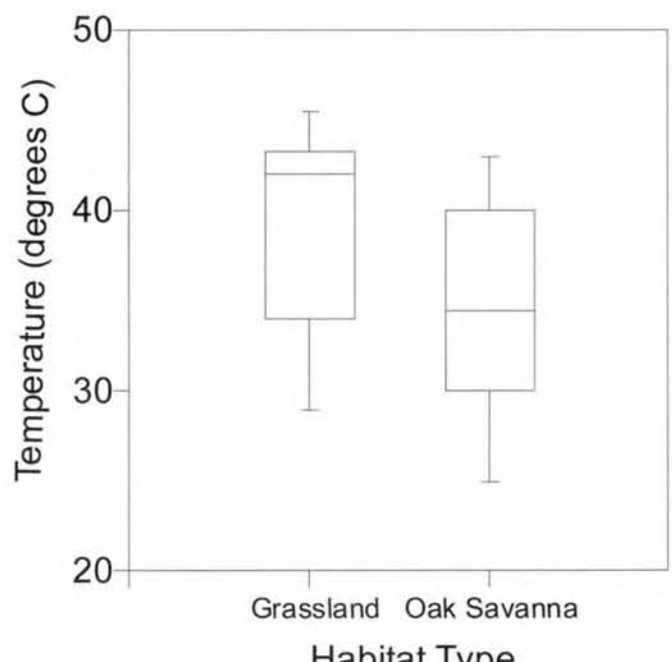

FIG. 1. Box plots: (median, 25th and 75th percentile, and range) comparing soil-surface temperatures between the two habitats in which *Aspidoscelis sexlineata viridis* was most commonly observed in Sauk County, Wisconsin.

ity by laying a glass-encased pocket thermometer (non-mercury) on the soil surface until it equilibrated, which did not exceed 5 min. Comparison of soil-surface temperatures selected by lizards between habitats was accomplished via a two-sample *t*-test conducted in Systat v. 10.0 (Point Richmond, California). The percentage of racerunner observations in a particular habitat was calculated by taking the number of observations in that habitat and dividing it by the total number of racerunner observations; however, we did not account for search effort within each habitat.

We observed active adult racerunners from 10 May–31 August in both years. The activity of hatchlings lasted several weeks longer in fall, with the latest observation occurring on 6 October. Thirty-nine observations were deemed acceptable based on the previously mentioned criteria. Of these, we recorded soil temperature on 36 occasions. In most cases, adult lizards were observed in either oak savanna (N = 23) or open grasslands and prairie (N = 15). These two habitats constitute a small portion (12.5%) of the study area (Table 1). The remaining individual (excluded from analyses) was found basking on rocky soil of a south-facing open bluff. The microhabitats in which lizards were observed had mean understory cover of 32% (range: 0–75%) and an estimated tree-canopy closure of 17.6% (range: 0–70%). Lizards were observed on soils characterized as either sand (N = 38) or soil/gravel mix (N = 1). The soil-surface temperatures selected by racerunners were relatively high (Fig. 1) and differed ($t = 2.34$; $P = 0.025$) between oak savannah (34.7°C) and open grassland (39.2°C).

The active season for adult racerunners at our study site (early May through late August) was 2–3 weeks longer than the mid-May through mid-August season proposed by Vogt (1981) for Wisconsin. The active season we observed was also slightly longer than the late May through mid-August active season proposed for the Great Lakes region by Harding (1997) and the mid-May through late August season proposed for Minnesota by Oldfield and Moriarty (1994). Although our observations are based on a small area within the state, this may be the largest population of this subspecies in Wisconsin (B. Hay, pers. comm.). However, we cannot eliminate annual variation in climate as a possible factor contributing to the differences between our estimate of activity period and the other sources. Nonetheless, because racerunners (1) are listed by the Wisconsin Department of Natural Resources (DNR; 2005) as a "Species of Greatest Conservation Need" and considered restricted in range or declining in other states within this region; (2) have short activity seasons (4 months or fewer) compared to populations in other parts of their range; and (3) their habitats in the upper Midwest, where protected, are often managed by burning, knowing the earliest and latest possible dates for racerunner activity may reduce management-related mortality.

Aspidoscelis sexlineata is widely reported to prefer open habitats (Fitch 1958; Harding 1997; Hardy 1962; Oldfield and Moriarty 1994; Phillips et al. 1999; Vogt 1981). Not surprisingly, lizards were never encountered in closed canopy habitats, such as lowland and bluffside mixed hardwood forests, which dominated the landscape adjacent to most of our racerunner observations. The high soil-surface temperatures apparently preferred by this subspecies were more commonly available in open-canopy habitats, but open grassland habitats may have been too hot (i.e., exceeding the upper preferred limit for this subspecies). This may partly explain why lizards were observed less often in open grassland than in oak savanna, although alternate hypotheses cannot be ruled out (e.g., predator or prey densities, etc.).

Our findings are relevant to those involved in the management and restoration of upper Midwest prairie habitats where this subspecies occurs. Because *A. s. viridis* is considered uncommon and declining in many upper Midwest states (Christoffel et al. 2002; Oldfield and Moriarty 1994; Phillips et al. 1999; Wisconsin Department of Natural Resources 2005), proper management of canopy and under-story vegetation in areas where this subspecies occurs is of critical importance to its conservation (Mushinsky 1985). Our results indicate that Prairie Racerunners are usually observed in two habitats that are rapidly declining throughout the United States: oak savannas and open grasslands. Therefore, protection or management of these habitats is critical, at least in this portion of the Prairie Racerunner's range.

Acknowledgments.—We thank S. Richter, P. West, and other employees of The Nature Conservancy (Madison, Wisconsin Chapter) for permission to access study sites, the private landowners who allowed us access to their property, the Department of Biological Sciences (UW-Milwaukee) for partial funding of this project, B. Hay for supplying equipment, J. Laedlein for help with GIS analysis, and T. Muehlfeld, T. Kessenich, and C. Bennell for field assistance. C. Berg, J. Coggins, and four anonymous reviewers commented on earlier versions of this manuscript, improving it significantly. Permission was granted from state and federal agencies to access the study site, and research was conducted under animal-use protocol (02-03 #145) issued by the UW-Milwaukee.

The Application of Skeletochronology to Estimate Ages of Three Species of Frogs in West Java, Indonesia

Skeletochronology has been used successfully to estimate age in temperate and sub-temperate frogs (Halliday and Verrel 1988; Khonsue et al. 2002; Morrison et al. 2004; Reaser 2000; Ryser 1988). In temperate species, lines of arrested growth (LAGs) in bones are usually distinct and are formed during winter (Halliday and Verrel 1988; Reaser 2000; Ryser 1988). Few attempts have been made to estimate age using this method in tropical frogs (Guarino et al. 1998; Khonsue et al. 2000; Kumbar and Pancharatna 2001; Pancharatna et al. 2000) and it has not previously been applied to Indonesian frogs.

As part of a population study of three species of edible frogs in Indonesia, we examined phalanges taken from toe clips of *Fejervarya limnocharis*, *F. cancrivora*, and *Limnonectes macrodon* to determine whether it is possible to estimate the ages of individuals of these tropical species using skeletochronology. For every frog captured, we recorded sex, body size as measured by SVL (snout–vent length) and mass, and clip code. Since each frog was numbered uniquely, phalanges used for skeletochronological analysis were taken from different toes. *Fejervarya limnocharis* and *F. cancrivora* were encountered in rice fields, and *L. macrodon* was found primarily at streams.

We analysed samples from 103 *F. limnocharis* (SVL = 15.68–53.00 mm), 35 *F. cancrivora* (SVL = 14.50–56.68 mm) and 42 *L. macrodon* (SVL = 47.06–105.22 mm). Samples of the rice field frog species were taken during surveys carried out between September 2001 and June 2002 in West Java province, Indonesia, in the Residencies of Bogor and Sukabumi. Samples from Bogor were taken from rice fields in Situ Gede (06°33'50.8"S, 106°44'10.2"E, elevation 220 m above sea level) and Caringin (06°43'22.4"S, 106°49'22.8"E, elevation 478 m asl) while samples from Sukabumi were taken from Ciptarasa (06°51'07.3"S, 106°30'22.9"E, elevation 810 m asl), and Panguyangan (06°52'13.1"S, 106°31'04.4"E, elevation 760–800 m asl); both are village enclaves within Mount Halimun National Park. Samples of *L. macrodon* were taken during surveys carried out in streams at Cilember (06°39'36.7S, 106°56'42.1"E) and Ciapus Leutik (06°39'48.0"S, 106°44'42.7"E) both in Bogor Residency, from June 2002 to May 2003. Mean monthly temperatures in the area normally vary by less than 10°C over the year. The Bogor and Sukabumi Residencies are one of the wettest regions in Java, with monthly rainfalls greater than 200 mm in most locations throughout the year (Whitten et al. 1997).

Clipped toes were stored in 4% formalin and returned to our laboratory at James Cook University, Australia for processing. Each toe was wrapped in sponge and placed individually in a cassette, then decalcified overnight (approximately 24 h) in 10% formic acid solution. Toes were then embedded in wax in a vacuum infiltrated processor and cut into sections transversely at 10 μm thickness using a rotary microtome. Sections were put on slides and stained with Mayer's Haematoxylin. The best and clearest sections were chosen for observations and were examined using an Olympus BH dual-head microscope at 100x magnification to view marks of skeletal growth. Due to staining problems (sections too dark or/and curled), which make interpretation difficult, sections from 7 *F. limnocharis*, 5 *F. cancrivora*, and 1 *L. macrodon* were not included in the analysis. Lines of arrested growth (LAG) were interpreted from the occurrence of hematoxylinophilic lines in the periosteal layer in sections taken from the central regions of the diaphysis. We examined the results by analyzing the differences of mean SVL between groups that have LAGs and no LAGs (*F. limnocharis* and *F. cancrivora*) and evaluated the relationship between body size and number of LAGs using Spearman's correlation (for *L. macrodon*).

LAGs appeared as faint lines in the periosteal layer of cross sections of phalanges of *F. limnocharis* and *F. cancrivora*, whereas in *L. macrodon* they were darkly stained and distinct lines (Fig. 1). The maximum number of LAGs found in samples from *F. limnocharis* and *F. cancrivora* was one and for *L. macrodon* was five. The most common state for all species was to have no LAGs visible (73% of *F. limnocharis*, 63% of *F. cancrivora*, and 61% of *L. macrodon*). One LAG occurred in 27% of *F. limnocharis*, 37% of *F. cancrivora*, and 20% of *L. macrodon*. Only *L. macrodon* had more than one LAG (10% with 2, 7% with 3, and 2% (1 individual) with 5).

There were no significant differences in mean body size be-

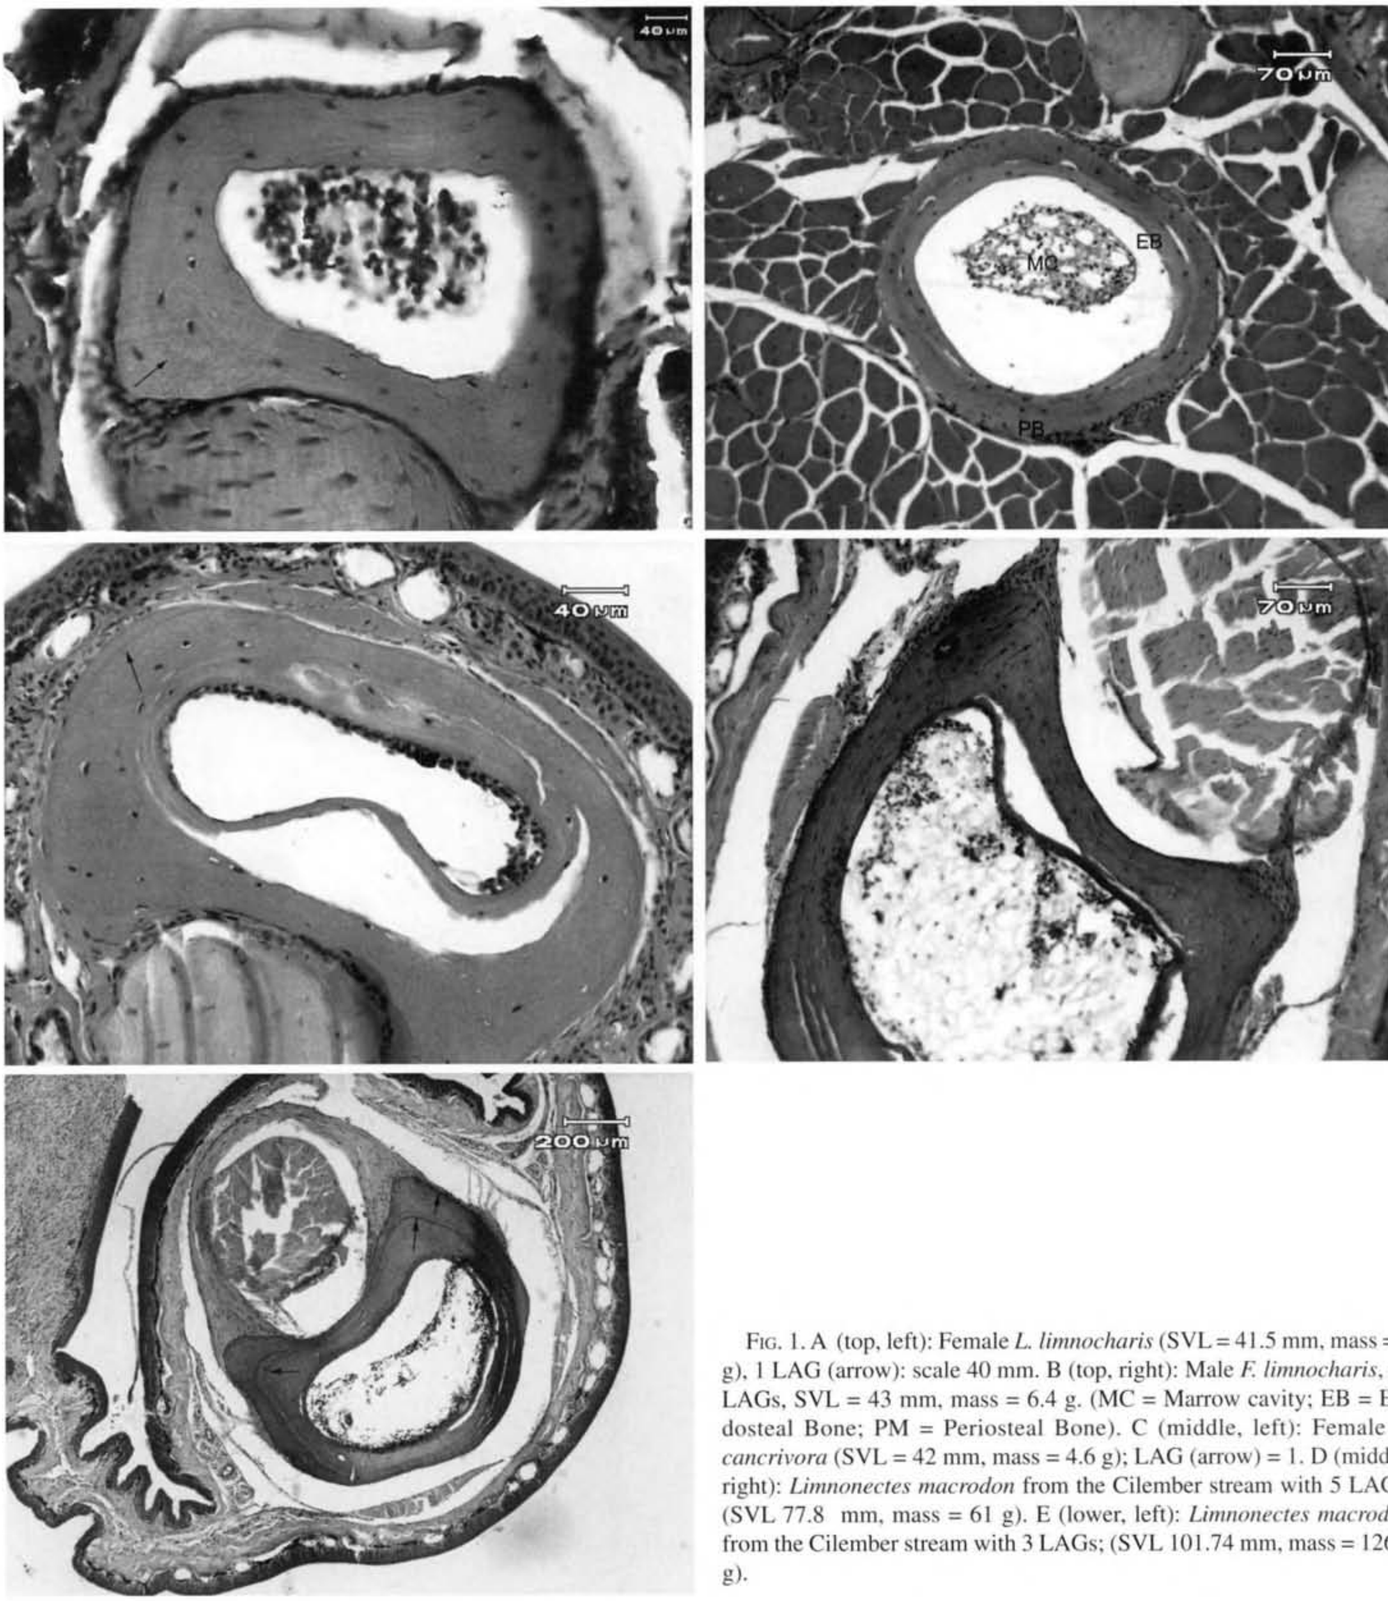

FIG. 1. A (top, left): Female *L. limnocharis* (SVL = 41.5 mm, mass = 5 g), 1 LAG (arrow): scale 40 mm. B (top, right): Male *F. limnocharis*, no LAGs, SVL = 43 mm, mass = 6.4 g. (MC = Marrow cavity; EB = Endosteal Bone; PM = Periosteal Bone). C (middle, left): Female *F. cancrivora* (SVL = 42 mm, mass = 4.6 g); LAG (arrow) = 1. D (middle, right): *Limnonectes macrodon* from the Cilember stream with 5 LAGs; (SVL 77.8 mm, mass = 61 g). E (lower, left): *Limnonectes macrodon* from the Cilember stream with 3 LAGs; (SVL 101.74 mm, mass = 126.5 g).

tween groups that had LAGs and no LAGs, both in *F. limnocharis* (t_{93} = 0.358, P = 0.723) and in *F. cancrivora* (t_{28} = 0.369, P = 0.723). However, there was a significant positive relationship between body size and LAG number in *L. macrodon* (Spearman correlation, r_s = 0.399, P = 0.01); larger *L. macrodon* tended to possess more LAGs than smaller individuals (Fig. 2). This suggests that the number of LAGs may reflect age in this species. However, since each LAG class spanned wide and overlapping ranges of snout-vent lengths, it is impossible to estimate age from the size of frogs.

Our results suggest that skeletochronology may not be useful on some species such as *F. limnocharis* and *F. cancrivora* that are active all year and live in environments in which temperature does not show major seasonal fluctuations, even when there are dis-

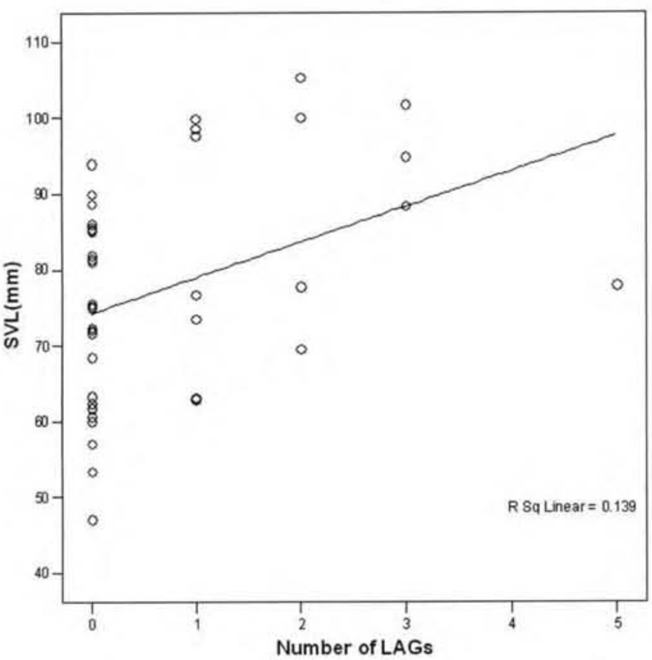

FIG. 2. Snout–vent length (mm) versus number of lines of arrested growth (LAGs) for *Limnonectes macrodon*.

tinct wet and dry seasons. Both species only showed weak LAGs, when any were evident. Population studies (Kusrini 2005) indicated that they remain in an area of habitat while conditions are favourable, but move on when conditions become unfavourable. Because individual paddy fields have varying seasonal patterns of filling and draining, sowing and harvesting, paddy-field systems taken as a whole tend to be largely aseasonal. The lack of seasonal effects on growth in these species could therefore be due to the frogs moving locally to favorable habitats as conditions change. It is also possible, however, that the age structure suggested by the LAGs we detected in these species is correct; both have been suggested to be short lived (Jaafar, 1994; Kusrini 2005).

Our results show that skeletochronology may be applicable to *L. macrodon*. LAGs found in *L. macrodon* were quite distinct, suggesting that growth was slower during certain times. In contrast to the paddy-field species, mark recapture data showed that *L. macrodon* is philopatric, remaining in place during the dry season but reducing its activity levels (Kusrini 2005). This suggests that the pattern of LAGs we found in *L. macrodon* may be due to changes in growth rate caused by seasonal rainfall patterns, with reduced growth during the dry season, which typically occupies three months each year.

Further study is required to validate that LAGs are formed annually in *L. macrodon*, either by clipping recaptured frogs in the future or possibly by examining museum specimens covering a wide range of SVL sizes.

Acknowledgments.—An Australian Development Scholarship (ADS), the Wildlife Conservation Society, Bogor Agricultural University, James Cook University, subcontracts to R.A.A. from US NSF IRCEB grants IBN-9977063 and DEB-0213851 (J. P. Collins, P.I.), and the Indonesian Reptile Amphibian Trader Association (IRATA) provided funds for travel, work in Indonesia, and laboratory work in Australia. Volunteers from Bogor Agricultural University helped us greatly during fieldwork in Indonesia, for this we thank them, especially Anisa Fitri, Sumantri Radiansyah and Dede M. Nasir. We thank Sue Reilly, Adam Felton, Richard Retallick, Sara Townsend, Kim Hauselberger, and Jodi Rowley for inputs and technical assistance during the laboratory work. This study was carried out under James Cook University Animal Ethics approval A 748.

An Improved Technique for Scale-Clipping of Small Snakes

Most population studies of snakes require that researchers visit the population under investigation for more than one season, and a reliable permanent marking method is thus required for long-term recognition of individual snakes. Scale-clipping was the first technique used for long-term marking of snakes (Blanchard and Finster 1933). Researchers have variously marked subcaudal scales, ventral body scales (scutes), or a combination of the two (Lang 1992). A drawback of this technique is that removed parts of scales can regenerate with time (Carlström and Edelstam 1946). Three additional disadvantages of scale-clipping have been observed: 1) it is time consuming; 2) it may draw blood and increase risk of infection; and 3) it may not be practical for small snakes (Weary 1969). Passive integrated transponders (PIT tags) have been tested on neonatal snakes without observable ill effects (Keck 1994), but use of this technology can be expensive (Morley 2002; Gibbons and Andrews 2004). However, compared to the use of PIT tags (Gibbons and Andrews 2004), cold branding with a mixture of dry ice and 95% ethyl alcohol as a coolant (Lang 1992), or heat branding (Winne et al. 2006), scale-clipping remains the most economical method for marking snakes, and has been in use for over sixty years. Typically, the selected scale is excised with a pair of small scissors (Blanchard and Finster 1933).

In September 2004, we initiated a population monitoring program for wetland and forest snakes in Taoyuan and Ilan Counties, northern Taiwan. Our scale-clipping technique is based on use of the 12-gauge hypodermic needle of a PIT tag injector. The hypodermic needle of the PIT syringe largely replaces the scissors when marking the snake, especially on small to medium sized individuals. First, the needle is inserted under the posterior end of the ventral or subcaudal scales (Fig. 1). It is then pushed under the ventral plate (scute) and through the dermis of the scale base on the other side of the scale (the underlying muscle should be exposed). The needle tip is then raised, rupturing the base of the ventral scale. This results in a well-defined triangular scar on the ventral scute (Fig. 2). The removed tissue can be preserved in ethanol for molecular studies. When the scale does not rupture as neatly as desired, a pair of scissors can be used to smooth out the margins. To date, we have marked seven snake species (*Amphiesma sauteri*, *A. stolatum*, *Elaphe carinata*, *Oligodon formosanus*, *Ptyas korros*, *Trimeresurus stejnegeri*, and *Xenochrophis piscator*) and >50 individuals over a six month period using this technique. We have experienced no problems in the execution of scale clipping and have observed scale complete regeneration.

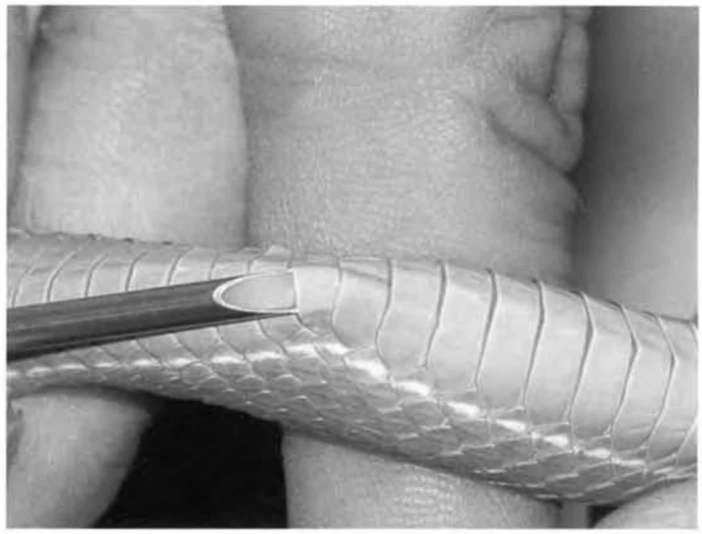

FIG. 1. The initial stage of inserting the hypodermic needle, as seen here demonstrated on the ventral scales of a female *Trimeresurus stejnegeri*.

FIG. 2. The scar and regenerated condition of the ventral scales of a *Trimeresurus stejnegeri* two months after it was made with the technique described herein.

Acknowledgments.—Special thanks are extended to Jin-Shiou Lin, Kun-Da Feng, Zu-Hao Chung, Jay-Long Wu and Chia-Hao Chang for assistance with fieldwork for this study.

A variety of methods have been used to study lizard populations including rubber bands, active searching and noosing (Campbell and Christman 1982; Karns 1986; Simmons 1987), pitfall traps (Fair and Henke 1997; Moseley 2004; Sutton et al. 1999), glue boards (Bauer and Sadlier 1992; Downes and Borges 1998; Durtsche 1996; Moseley 2004; Whiting 1998), extraction by hook (Bedford et al. 1995), conspecifics as bait (Zani and Vitt 1995), crickets as bait (Durden et al. 1995), refuge tubes (Moseley 2004; Strong et al. 1993), and a water-spray method (Estrada-Rodriguez et al. 2004). All of these can be used to capture lizards with varying degrees of effectiveness depending on the species, but in some cases they result in lizard mortality or stress. For example, in the southeastern United States many traps (pitfalls, glue boards, etc.) that capture anoles are frequented by red imported fire ants (*Solenopsis invicta)* that prey on captive lizards (K. Moseley, pers. comm.). Also, lizards may die before traps are rechecked or may go for extended periods without food. Likewise, techniques such as removing bark from dead wood alter the local habitat.

Burlap bands are a simple, inexpensive, and effective way to catch or monitor bole-active lizards, and may be useful for sampling other herpetofauna. Burlap bands have been used to monitor insect pests occurring in orchards (Mizell and Schifffhauer 1987; New 1967) or to simulate bark where insects hide in both hardwood (Campbell and Sloan 1977) and pine (Horn 2000) forests. Because burlap bands often harbor insect prey and serve as a refuge from predators or adverse climatic conditions, they may be effective at sampling a number of arboreal lizard species. Herein, we describe our observations of Green Anoles (*Anolis carolinensis*) and other herpetofaunal species beneath burlap bands used for monitoring insects in mature pine forests in the southeastern Coastal Plain.

Our study plots were located on the Savannah River Site, a National Environmental Research Park in the Upper Atlantic Coastal Plain of South Carolina, USA. Stands consisted of loblolly pine (*Pinus taeda*) ca. 50–55 years in age in well-drained upland soils. We placed burlap bands (Fig. 1) around mature pine trees that had been scraped to remove the outer bark at a height of 1–1.5 m. Bands were 1 × 1 m pieces of burlap fabric folded in half and sewn along the fold ca. 3 cm from the folded edge. A 1.5 m-long piece of cotton rope was threaded through the fold and tied around the tree to hold the band in place (Fig. 1). Burlap bands were checked by untying the rope and slowly pulling the burlap away from the tree while walking around the tree and examining the bole underneath.

On 19 October 2004 and 20 April 2005 we monitored 240 burlap bands spaced ca. 50 m apart throughout 16 10-ha plots (15 bands per plot). It took ca. 8 h to check all 240 burlap bands on each sampling date. We selected these dates to coincide with Moseley's (2004; see below) sampling periods in previous years on the same plots so we could compare our results to his. Burlap bands were always in the field, and data reported here are from two days of observation following long intervals without checking bands. We collected 45 Green Anoles of all age classes, averaging one anole for every 10.6 bands checked. We also observed other species beneath bands such as Eastern Fence Lizards (*Sceloporus undulatus*) (N = 7), a Gray Tree Frog (*Hyla chrysoscelis*) (N = 1), a juvenile Black Ratsnake (*Pantherophis obsoleta*) (N = 1), and Broad-headed Skinks (*Eumeces laticeps*)

FIG. 1. Burlap band used for sampling arboreal insects and herpetofauna on pine tree boles at the Savannah River Site near Aiken, South Carolina.

(N = 2). Skinks have also been noted under burlap bands on both pine and hardwood trees in a nearby forest on the Savannah River Site (W. Gibbons, pers. comm.).

Green Anoles are commonly encountered in the southeastern U.S., yet it is unclear whether existing sampling techniques represent actual population levels. For example, Greenberg et al. (1994) conducted a study in Florida scrub habitat using pitfall and funnel trap arrays to assess their relative effectiveness for capturing local herpetofauna. They captured a total of 38 anoles during a 13 month period.

Recently, Moseley (2004) sampled herpetofauna (using pitfalls, refuge tubes, and glueboards) on the same plots used in this study and captured a total of 111 Green Anoles during 14 trap-days in October 2002 and 24 trap-days in April 2003. Glueboards (N = 96) resulted in 1.97 anoles captured/trap-day, pitfall trap arrays (N = 12) resulted in 0.63 anoles/trap-day, and refuge tubes (N = 192) resulted in 0.32 anoles/trap-day. In comparison, we averaged 22.5 anoles/observation-day using burlap bands. We acknowledge limitations in these comparisons becasue varying methods sample the local community differently. However, our data show that burlap bands can be an efficient technique for targeting specific species such as Green Anoles and other arboreal lizards.

Refuge tubes are similar to burlap bands in that they are non-destructive, but refuge tubes on tree boles were not as successful in attracting anoles (K. Moseley, pers. comm.). Unlike pitfall traps and glueboards that can harm or kill captured lizards, burlap bands were non-destructive (i.e., lizards were not captured until observed, thus avoiding mortality, stress, or environmental hazards). For example, glueboards resulted in 25% mortality of anoles captured in October 2002 and 41% mortality in April 2003. The increased mortality in April was likely because of increased temperatures and fire ant activity (K. Moseley, pers. comm.).

Burlap bands provide an inexpensive monitoring tool for studies of lizards and other reptiles. Although our sampling was limited to pine forests in South Carolina, this technique should be useful for sampling bole or canopy active lizards in other forest types. This might be especially true in tropical regions where burlap is widely available and sampling may be sporadic. More research is needed to determine the efficiency of this technique for collecting different species under varying conditions and whether observations beneath burlap bands reflect actual lizard abundance.

Acknowledgments.—We are thankful to the U.S. Department of Energy for access to the Savannah River Site. Funding for this project was provided by the U.S. Department of Energy-Savannah River Operations Office through the U.S. Forest Service under Interagency Agreement DE-AI09-00SR22188. We thank Danny Dyer for help with fieldwork and Kurtis Moseley for access to data and helpful comments on the manuscript.

Trapping is an effective means for sampling and monitoring amphibian communities within and across habitats. Amphibian trapping can involve the use of drift fences with funnel or pitfall traps (Dodd 1991; Enge 1997), or poly-vinyl chloride (PVC) pipe refugia (Boughton et al. 2000; Zacharow et al. 2003). Most amphibian monitoring projects based on trapping focus on either drift fence trapping or PVC pipe refugia, not a combination of both (Boughton et al. 2000; Dodd 1991; Enge 1997). Trapping was adopted as one of our methods to inventory amphibians in a seasonally flooded marsh habitat in Everglades National Park (ENP), Florida, USA. However, trapping in marsh habitat in ENP posed three challenges: a thin layer of marl soil with exposed limestone, a lack of trees on which to hang PVC pipe, and a wilderness designation that precludes mechanical disturbance to soil or substrate. We designed trapping structures that were non-invasive to the environment, portable, and combined PVC pipe refugia with funnel trapping along a drift fence.

Each trapping structure comprises the following items: one 2.5 cm × 10.2 cm × 305-cm wood plank, two 2.5 cm × 10.2 cm × 30.5-cm wood extensions for stability on each end, three 61-cm wood stakes, and one 122 cm × 305-cm piece of silt fencing. Three 1.2-m lengths of 5.1-cm-diameter PVC pipes were used along with three small elastic cords with hooks to support the top of the drift fence. We used collapsible, rectangular minnow traps measuring 39 cm × 24 cm × 24 cm with a 5.5 cm diam opening on each end (Nylon Net Company, Model MT4). Each structure was assembled by attaching wood stakes with screws to a 305-cm plank at both ends and the center. One 30.5-cm-long wood extension was attached perpendicular to each end of the structure for stability. The

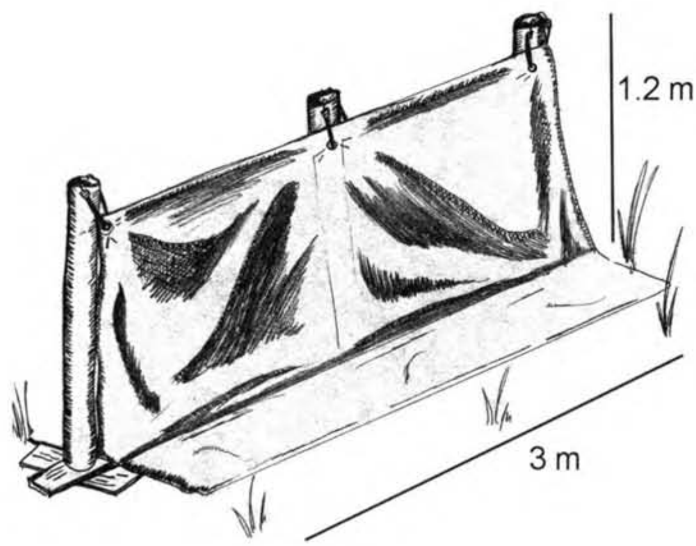

Fig. 1. Trapping structures were assembled from wood planks, stakes, silt fencing and PVC pipes to form a portable, non-invasive structure used to trap amphibians.

silt fencing, available commercially through construction suppliers (Enge 1997), was stapled to one side of the structure leaving a 30-cm flap at the bottom. PVC pipes were placed on the stakes and the drift fence was held taut by attaching small elastic cords from grommets to the PVC pipes (Fig. 1). We constructed 40 trapping structures at a cost of US $47.55 each, excluding the cost of minnow traps, and an average time of 0.3 h per structure.

Assembled trapping structures (~ 4.5 kg) were carried to the study site (100–300 m from road), along with bricks, chain, and PVC pipes (several trips are needed to get all supplies to sites). Two bricks were placed on each end of the trapping structures for stability against wind and water, and metal link chain (5-mm diameter) was draped along the flap of the drift fence to secure it to the uneven ground. Trapping structures were completed by placing one minnow trap at both ends of the drift fence (Fig. 2). Minnow traps were held snug against the fence with stakes where there was enough soil, and with rocks or bricks at other sites.

We sampled amphibians at two sites in ENP (Main Park Road and Context Road). Each site had five plots and each plot contained an array of four trapping structures arranged in an open square design for a total of 12 PVC pipes and eight minnow traps

Fig. 2. PVC pipes and collapsible minnow traps were used in combination to trap amphibians.

TABLE 1. Number of species captured using portable, non-invasive trapping structures at two sites in Everglades National Park.

Species	Main Park Road			Context Road		
	PVC Pipe	Minnow	Total	PVC Pipe	Minnow	Total
Oak Toad (*Bufo quercicus*)					1	1
Green Treefrog (*Hyla cinerea*)	197	1	198	746	1	747
Squirrel Treefrog (*Hyla squirella*)	802	2	804	239	2	241
Cuban Treefrog (*Osteopilus septentrionalis*)	3		3			
Southern Leopard Frog (*Rana sphenocephala*)		2	2		13	13
Green Anole (*Anolis carolinensis*)	31	13	44	107	11	118
Brown Anole (*Anolis sagrei*)		2	2			
Striped Mud Turtle (*Kinosternon baurii*)					1	1
Striped Crayfish Snake (*Regina alleni*)		1	1			
Common Garter Snake (*Thamnophis sirtalis*)					1	1
Total captures	1033	21	1054	1092	30	1122

per plot. Twenty trapping structures were used in each of the sites with a total of 60 PVC pipe refugia and 40 minnow traps per site. Sites were sampled monthly and each trap was checked on two consecutive days. Between trapping events, the elastic cords were unhooked, the drift fence was laid down, and minnow traps were closed.

We captured five amphibian species and five reptile species between July 2004 and August 2005; four were caught in PVC pipe refugia and nine in minnow traps (Table 1). No aquatic salamanders were caught using these trapping structures, and only two non-hylid anuran species were captured in the minnow traps (Table 1). We had 2,176 total captures and of those, 51 were from minnow traps and the remainder were from PVC pipe refugia (Table 1). Green Treefrogs (*Hyla cinerea*, N = 943), and Squirrel Treefrogs (*Hyla squirella*, N = 1041), captured in PVC pipes, accounted for the majority of captures. Cuban Treefrogs (*Osteopilus septentrionalis*), an introduced hylid frog species, were also captured three times in PVC pipes at the Main Park Road site. All animals captured were counted and released with no effort to mark them; therefore, the same individuals may have been captured on multiple dates.

The number of species and individuals captured in minnow traps was very low relative to Dalrymple (1988) who captured 695 individuals of 30 species of reptiles and amphibians in minnow traps in seasonally flooded prairie habitat in ENP. Differences in array design and construction, length of study, and amount of time traps were opened all may have contributed to the differences in the number of species and individuals trapped. Dalrymple (1988) trapped for 2.5 yrs and his traps were open 50% of the time. He used a three-array design in prairie habitat; each array consisted of four 15-m lengths of shade cloth that intersected to form an "X." These arrays were configured by attaching shade cloth to iron reinforcing bars that had been hammered into the limestone. Our five arrays at each site consisted of four 3-m non-invasive trapping structures that did not penetrate the limestone and were only opened for two nights per month for a total of 24 nights.

Corn (1994) recommends a drift fence design with three wings, each at least 5 m in length, radiating out from a central point and that funnel traps be placed in the middle of each array on either side. Our trapping structures could be made longer to meet these recommendations. A trapping structure 5 m in length may still be portable or two structures could be attached lengthwise to form a longer single structure. Alternatively, the trapping structure could be used with only PVC pipes, omitting the silt fence and funnel traps due to the success at capturing hylid frogs in PVC pipes and lack of success with the funnel traps. However, this design worked extremely well for capturing treefrog species and satisfied all requirements for use in protected areas.

Acknowledgments.—We thank Christina Ugarte and Micheal Cherkiss for reviewing this manuscript. Christina Ugarte also provided the excellent drawing of the trapping structure. Jeremy Spires, Chad Lykins, and Michelle Casler provided valuable field assistance. Andy Maskel provided assistance assembling the trapping structures. This work was completed under National Park Service permits EVER-2004-SCI-0046 and EVER-2005-SCI-0052, and was funded by the U.S. Geological Survey. All research was approved by University of Florida under IACUC protocol number D587.

Methods for attaching radio transmitters to caudate amphibians are problematic (e.g., Blais 1996; Matsui 2003) because of their delicate skin, shape, and use of fossorial habitats and burrows. Available methods include surgical implantation (Blais 1996; Jehle and Arntzen 2000; Madison 1997; Madison and Farrand 1998; Stauffer et al. 1983), forced ingestion (Blais 1996; Schabetsberger et al. 2004), and suturing transmitters to animals (Blais 1996; Kakinoki 2000; Ota 1998). However, these methods have had limited use.

The Japanese Giant Salamander, *Andrias japonicus*, is a gigantic stream-dwelling salamander protected by the Japanese government (Matsui 2000). Radio telemetry can provide useful life history data for incorporation into conservation actions. Matsui (2003) surgically implanted transmitters subcutaneously into the hind limb of *A. japonicus*, but five of eight transmitters fell off within 16 days. A suturing attachment method was tested with eastern hellbenders, *Cryptobranchus a. alleganiensis*, where transmitters were attached to the keel or tip of animals' tails and remained attached for 1–8 weeks (Blais 1996). Kakinoki (2000) sutured transmitters to *A. japonicus* tails using nylon line and a pair of plastic washers, analogous to an ear-piercing. Eleven of 13 transmitters remained more than 100 days, and three lasted more than 10 months. However, he sutured only relatively large adults (68.2–86.2 cm TL, 2140–4160 g), and the usefulness of the method for smaller adults is unknown. In addition, damage to salamanders and the cause of transmitter loss have not been reported. We tested the suturing method on 18 adult *A. japonicus* of various sizes to examine transmitter retention period, damage to salamanders, and cause of transmitter removal.

Materials and Methods

Our study was conducted from July to November 2002 and in April 2003 at two sites in the Chugoku Mountains, western Honshu, Japan. The Tsuchiya River in Tottori Prefecture is relatively undisturbed with plentiful rock cover flowing through woodlands. The average stream width is approximately 5 m. The Ouchi River in Hiroshima Prefecture is more heavily disturbed with three dams on a 300-m reach of river. Our study reach partially runs through rice paddies and cement walls line the riverbanks to prevent erosion. Average stream width is approximately 3 m. Water depth in both rivers is less than 50 cm except in deep pools.

We used BD-2 (1.2 g or 1.8 g, 17 × 9 × 7 mm, 21 cm whip antenna, 9–16 week battery life) and PD-2 (3.5 g, 23 × 12 × 6 mm, 22 cm whip antenna, 6 month battery life) model transmitters (Holohil Systems Ltd., Ontario, Canada). The bottom edges of transmitters were embedded with a swivel or wire ring, used to connect to tail attachment assemblies (Fig. 1). Specifications for attachment assembly materials were as follows: polyethylene plastic washer (15–19 mm diameter × 1 mm thick, 0.3 g × 2); monofilament nylon line (0.78 mm diameter and 23 kg test fishing line for 30–39.9 cm TL salamanders, 1.17 mm diameter and 45 kg test fishing line for salamanders > 39.9 cm TL); and aluminum crimp sleeve (3.5 × 2.5 × 1 mm, two sleeves with nylon line 0.1 g, together for a total of 0.7 grams). Plastic washers were cut from a plastic container and sanded smooth. The inside dimensions of sleeves were 2.5 × 1.2 mm. Sleeves come with 7.3 mm lengths, but were cut to 1 mm length. In Japan, these sleeves are common in electronics shops and are available in saltwater fishing tackle shops in the U.S.A.

Salamanders were held without anesthesia in a halved PVC pipe along the stream bank while we attached transmitters. We covered

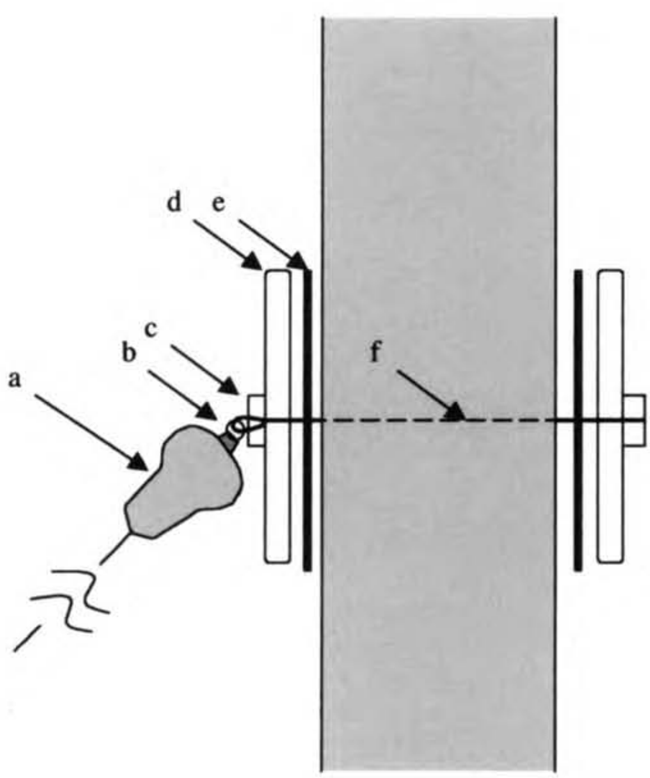

FIG. 1. Diagram of a completed radio transmitter attachment assembly in the upper portion of the tail of a Japanese Giant Salamander (shaded part of figure), including: a) radio transmitter; b) swivel or wire ring; c) aluminum crimp sleeve; d) polyethylene plastic washer; e) foam polyethylene cushion; and f) monofilament nylon line.

salamanders from head to mid-dorsum with a wet cotton bag or towel to keep them calm and wet (Tochimoto 1994). Attachment procedure was similar to Kakinoki (2000). In overview, the procedure entailed attaching a transmitter to a monofilament line with a small loop, then threading the line through the salamander's tail and fastening the line, transmitter, and two plastic washers to the tail using aluminum crimps (Fig. 1 and 2). Before the procedure, a 50 cm length of nylon line was superglued to a sewing needle (5 cm long, 1 mm thick) and sanded smooth. An end of nylon line was then passed through an aluminum crimp sleeve and the swivel ring of a transmitter and back through the aluminum crimp. The aluminum sleeve was then crimped tight on the line, thus creating a small loop in the nylon line around the swivel ring of the transmitter and crimped together (Fig. 1). The needle was then passed through a plastic washer. Needle and line were sterilized with 70% ethanol and, with washer and transmitter attached, were passed through the tail of the salamander. The device was attached at a location between 1/2 and 2/3 the length of the tail back from hind legs, and approximately 3/4 of the height of the tail at the point where the tail musculature and fin meet (Fig. 2). The needle was then passed through the second washer on the other side of the tail and through the second aluminum crimp sleeve. This sleeve was crimped tight on the nylon line and cut. There was approximately 5–10 mm slack between the salamander's tail and the plastic washers to prevent irritation by the washer. Tagged salamanders were released at the point of capture. With practice, the attachment procedure took two people approximately 5 minutes. We also tested foam polyethylene cushions (slightly larger than the resin washer, 1 mm thick) by inserting them between resin washers and one salamander's skin during attachment (Fig.1).

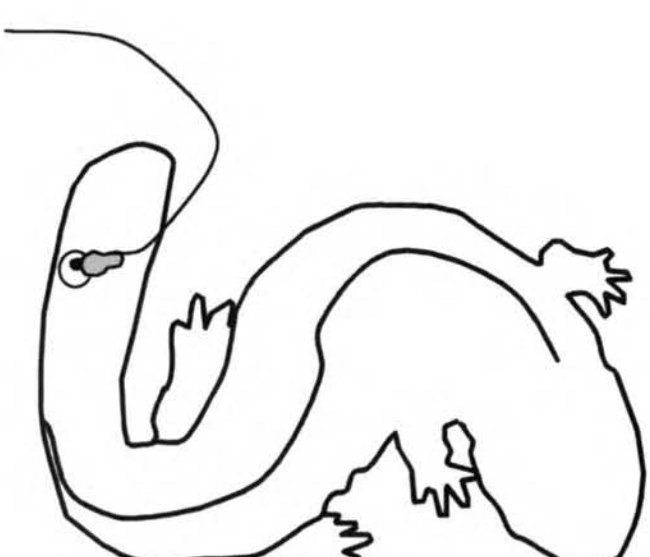

FIG. 2. Japanese Giant Salamander with radio transmitter and attachment assembly

In the Tsuchiya River, transmitters were attached to twelve individuals (Table 1; 8 males, 3 females, 1 unknown). Eleven of 12 individuals were tagged once and one was tagged twice using a total of one PD-2 and 12 BD-2 (8 large, 4 small) transmitters. Total salamander length (TL) ranged from 37.1–68.5 cm, while body mass was 320–2160 g. In the Ouchi River, large BD-2 transmitters were attached to six individuals once (Table 1; 3 males, 1 female, 2 unknown). Salamander TL ranged 32.2 –77.5 cm, while body mass was 228–3880 g. Transmitter packages weighed 1.9 g or 2.5 g (BD-2) and 4.2 g (PD-2), less than 1 % (0.1–0.8%) of the body mass of tracked salamanders.

We tracked salamanders with a 3-element Yagi or loop antenna (Antronics, Inc., Illinois, USA) and a model CE-12 receiver (Custom Electronics of Urbana Inc., Illinois, USA). We received transmitter signals with a 3-element Yagi antenna from about 100–130 m on a road above the stream. Under suboptimal tracking conditions, such as near stream bends, water gaps, or while wading in the stream, transmitter range was 40–50 m.

Results and Discussion

Transmitter retention period.—In the Tsuchiya River, the mean retention period was 97.9 days (SD = 37.7, range = 22–185). Twelve of 13 (92%) transmitters remained more than two months, one of 13 (8%) transmitters was shed in 22 days (Table 1). Five of the 13 (38%) transmitters were recovered but seven were lost because these salamanders settled in refuges such as deep cavities under rocks, artificial rock walls, or bank burrows just before battery death. In the Ouchi River, mean retention period was 44.3 days (SD = 33.0, range = 10–112). Of the six transmitters, four (67%) were shed within 2 months, one was retained for more than 2 months, and one was lost in artificial rock walls after 39 days (Table 1). Mean retention period differed between the Tsuchiya and Ouchi Rivers (Wilcoxon-Mann-Whitney test: $P = 0.018$). There was no correlation between retention period and TL at either site (Tsuchiya: $r = 0.01$, $N = 13$, $P = 0.97$; Ouchi: $r = 0.49$, $N = 6$, $P = 0.12$).

Cause of removal.—We confirmed five (Ouchi: 4, Tsuchiya: 1) cases of shed transmitters. In the Ouchi River, the first transmitter was entwined in grass roots in an undercut bank, and the assembly remained on the salamander's tail until it was recaptured a few days later. The second and third transmitters were recovered from beneath broken slabs of concrete. The fourth transmitter was found in a perched rice paddy on the ground where it converged with the stream. This transmitter did not catch on vegetation, but the transmitter's swivel ring was broken, possibly by a predator. In the Tsuchiya River, one transmitter was caught in accumulated twigs at the river's edge, and we recovered the assembly from the salamander after two weeks.

Mass change.—We assessed mass change between initial radio-tagging and recapture in five salamanders. Two males in the Tsuchiya River lost 14 g (1.9% of body mass) and 4 g (0.6%) after 77 and 67 days respectively. One male and female gained 40 g (1%) and 15 g (1.2%) after 112 days and 36 days in the Ouchi and Tsuchiya Rivers, respectively. A gravid female in the Tsuchiya first lost 55 g (5.2%) after 99 days and then regained 45 g (4.5%) after 185 days. We did not consider these changes to be significant because they were within mass changes observed in non-transmittered individuals (S. Okada, unpubl. data).

Injuries.—We observed two individuals with sores where the skin made contact with resin washers. These were in the Ouchi and Tsuchiya Rivers after 10 days and 22 days, respectively. The individual from the Tsuchiya had its attachment assembly removed and the salamander's injury had healed upon recapture in 16 days. In the Ouchi, another individual showed slight skin abrasion (about 5 mm diameter) at the point of contact with the plastic washer opposite of the transmitter after 112 days. It appeared that we had attached the transmitter assembly relatively tightly to injured individuals. In the one case where foam polyethylene cushions were used, the cushions were worn down to 0.5 mm after 185 days, but no sores were observed, therefore we recommend their use in the future. It is also possible that in situations where transmitters were recovered but the salamander was not observed injuries might have occurred.

Conclusion.— The suturing method was reliably effective for 2–4 mos. in our relatively short-term radiotelemetric study of multiple-sized adult *A. japonicus* in the Tsuchiya River. We anticipated that transmitters would snag on rocks. However it was not a problem in the Tsuchiya River even with plentiful rock cover in the stream. The Ouchi River, and areas of similar habitat, seem less suitable for the suturing method. The Ouchi River had various obstacles such as roots and broken concrete with sharp edges and most transmitters remained attached only approximately one month. Internal attachments such as surgical implantation or forced ingestion are likely more effective in these circumstances.

Our method was originally designed to minimize transmitter loss and salamander injury. However, future modifications such as thinner nylon line might prevent injuries such as skin sores because transmitters could be shed more easily when they become snagged. We also recommend attaching transmitters with approximately 10 mm slack between the washers and the salamander. Our suturing method is a viable option for researchers involved with *A. japonicus* telemetry because of its low cost, and ease of application. Although injuries occurred in at least three out of 18 individuals, our suturing method reduced injuries compared to a study of hellbenders using tail suturing (Blais 1996); attaching transmitters to tails with steel pins led to either chafing of skin or tearing and a subsequent hole in the tail following a few weeks in 11 of 12 salamanders (Blais 1996). Our method would also be applicable for other cryptobranchid species and large aquatic salamanders.

Acknowledgments.—We thank Kazuo Hoshikawa and Nobuo Tsurusaki for encouragement and support throughout this study, Shunsuke Kakinoki for providing valuable comments on transmitter attachment, and Jeff Humphries for recommending radiotelemetric studies and help with field research. Jed Kissane, Bill Sutton, Mizuki Takahashi, and two anonymous reviewers provided helpful comments on the manuscript. We are grateful to the Tottori and Hiroshima Prefectural Boards of Education for granting permits for our project.

Elastic Hair Bands: An Effective Marking Technique for Lizards in Mark-Recapture Studies

LEONARDO B. RIBEIRO

Many studies of lizard species require individuals to be captured, marked, and then released. Commonly two methods are used to mark individuals: permanent marking via toe clipping (see Waichman 1992; Woodbury 1956), or temporary marking by painting unique color combinations of dots on the animal with nontoxic paint. Alternative techniques such as radio transmitters (e.g., Losos et al. 1990) and passive integrated transponder (PIT) tags may be difficult to place in small reptiles (Bloch and Irschick 2004), and can be expensive. A recently developed method is to sew unique combinations of small colored beads into the base of the tail or nape of the neck (e.g., Martins et al. 1998), but like toe clipping, this method is invasive and may not be appropriate for all types of field studies or species.

Toe clipping may negatively affect locomotor performance and survival in some lizards (Bloch and Irschick 2004). Likewise, temporary marks using paint may be lost quickly via skin shedding, reducing their long-term efficacy in observational studies. We used an alternative method to mark terrestrial lizards of small to moderate body size, which causes no injury, and facilitates long-term observation and identification of individuals in behavioral studies. We used elastic hair bands (available in hair accessory stores), which are available in a variety of colors and diameters and can be fitted to a lizard's neck to allow individual identification. The hair bands are made of silicone, which is nontoxic, unreactive, and water-resistant.

We marked adult *Tropidurus torquatus* (Iguania: Tropiduridae), a common species of open formations, with these elastic bands to estimate their home-range sizes. Our study occurred during portions of the reproductive (November 2004 to February 2005) and nonreproductive (from March to June 2005) seasons on a rocky outcrop approximately 60 × 90 m in the Toledos district, Juiz de Fora municipality, Minas Gerais State, Brazil (21°48'27.5"S, 43°35'31.7"W; 697 m elev., datum: WGS 84). During a four-day period each month, we collected lizards once with glue traps (Rodda et al. 2005), and then used sightings of the same individuals to estimate home range size. The diameter of the elastic hair bands varied from just over 15 mm for the smallest reproductive female to 25 mm for largest reproductive male, and each individual had up to two bands of different colors. Elastic hair bands did not appear to affect lizard movement and remained intact on lizards for three months or longer, allowing a satisfactory period of observation and data collection.

Adult male *T. torquatus* averaged larger snout–vent length (88.4 ± 11.8 mm; range = 70.6–117.7 mm; N = 42) than adult females (78.9 ± 9.4 mm; range = 65.2–95.0 mm; N = 60) (*t*-test; $t = -4.413$, $df = 101$, $P = 0.0001$). During the reproductive season 378 sightings were recorded for 48 lizards (29 females and 19 males) with hair bands, and in the nonreproductive season 510 sightings for 73 lizards (42 females and 31 males) were recorded. Mean number of sightings per individual during the reproductive and nonreproductive seasons was 5.3 and 7.9, respectively. Eleven females and eight males were sighted over eight months of study during which they were recaptured and their hair bands replaced because of wear and fading of their color. Twenty-one *T. torquatus* were recaptured that had lost parts digits on their forelegs and/or hind legs, which, had toe-clipping been used, would have resulted in misidentification of individuals, whereas hair bands allowed uninterrupted individual identification. Loss of toes can result from biting during territorial disputes (LBR, pers. observ.).

In our study of *T. torquatus* elastic hair bands proved effective, non-obtrusive, long-lasting, and inexpensive, but care must be taken to minimize the number and diameter of bands used to insure that injuries do not result. This simple technique should be applicable in mark-recapture studies of small to moderate-sized lizard species living in a variety of habitats, so long as the species has a distinct neck (i.e., head much larger than neck diameter) and coarse scales (e.g., most skinks could slip the band over their heads). Like any marking technique using color (e.g., nontoxic paint or colored beads), this method may also be unsuitable for studies of social status or mate choice if the focal species uses color for communication. We therefore recommend that investigators validate that the color-marking technique they choose does not interfere with the questions being asked of their study species.

Acknowledgments.—We thank M. Van Sluys, M. Kiefer, G. Colli, and C. Galdino for invaluable research suggestions, and L. Vitt and anonymous reviewers for helpful comments on a previous draft of the manuscript. This study was supported by a grant from Coordenação de Aperfeiçoamento de Pessoal de Nível Superior (CAPES) to LBR. Research involving animals was in accord with the Ethical Principles of Animal Experimentation adopted by the Brazilian School of Animal Experimentation (COBEA), with approval of the Commission of Ethics in Animal Experimentation (CEEA) from the Research Rectory of Federal University of Juiz de Fora (Protocol 010/2005-CEEA), and under permission of IBAMA (Permit 261/05-NUFAS/MG and Process 02015.010660/05-88).

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 37, Number 1 (March 2006).

CAUDATA

AMBYSTOMA TIGRINUM MAVORTIUM (Barred Tiger Salamander). **EXTRALIMITAL POPULATIONS**. The natural range of *Ambystoma tigrinum mavortium* extends from central Nebraska to south Texas, USA (Conant and Collins 1991. Reptiles and Amphibians Eastern and Central North America, Houghton Mifflin Co., Boston, Massachusetts). The common practice of using Tiger Salamander larvae (water dogs) as fish bait has resulted in introductions of *A. t. mavortium* beyond its natural range (Petranka 1998. Salamanders of the United States and Canada, Smithsonian Press, Washington 587 pp.).

We report extralimital populations of *A. t. mavortium* from the unincorporated communities of Alpine and Ramona, San Diego Co., California. We consider both populations to be established because of the documentation of larvae (Alpine) or recently transformed individuals (Ramona). Specimen vouchers from the Alpine population have been deposited in the herpetological collection of the California Academy of Science, San Francisco, California (CAS). Vouchers were also sent to H. Bradley Shaffer, Department of Zoology, University of California, Davis, California, for genetic analysis.

On 6 February 1996, *A. t. mavortium* larvae (ca. 30 mm TL) were first detected in the vicinity of upper Chocolate Canyon in the unincorporated community of Alpine (R2E T15S Sec 29). Subsequent surveys resulted in additional observations of *A. t. mavortium* larvae: Spring 1996 (ca. 35 mm TL); 16 March 2001 (ca. 25 mm TL; CAS 233270); 28 March 2003 (ca. 17 mm TL; CAS 233721); 4 April 2003 (ca. 35 mm TL; CAS 233274); 4 May 2003 (ca. 43mm TL); April 2004; and 12 March 2005 (ca. 50mm TL; CAS 233723). Three of the larvae collected in 2003 were maintained in aquaria and photographed 25 months later to determine the pattern and coloration of individuals representing this population. Additional locality records of *A. t. mavortium* within the town of Alpine include a surface-active adult taken during Winter 1994 (R2E T15S Sec. 32), another on 12 January 2005 (R1E T16S Sec. 11), as well as the excavation of an adult from a residential garden in Spring 1999 (R2E T15S Sec. 33). Although no specimens were collected from these three additional locations, both surface-active individuals were photo documented. The Alpine population is now known to occupy an area of both the San Diego River watershed having been found in the area of upper Chocolate Canyon, and the Sweetwater River watershed, occurring in an unnamed drainage along Harbison Canyon Road.

Additional records of *A. t. mavortium* within San Diego Co. include three individuals captured within a few meters of the West Branch drainage located southeast of the unincorporated community of Ramona (R1W T13S Sec. 36). In Spring 2002, an adult was captured, and during Spring 2003, on separate dates, a recently transformed individual and an adult were captured. Individuals were photo documented prior to being released at the places of capture. This population also occurs within the San Diego River watershed.

Due to the limited amount of information, aspects of these populations such as source of introduction, length of time as an established population, population size, and the extent of their distribution remain unresolved.

This note provides source information for the *A. tigrinum* population of Alpine, San Diego Co., represented on the range map (extreme southwest portion of mainland California) in Stebbins (2003. Western Reptiles and Amphibians, 3rd. ed., Houghton Mifflin Co., Boston, Massachusetts), as referenced in Jennings (2004. An Annotated Check List of the Amphibians and Reptiles of California and Adjacent Waters, California Dept. Fish and Game 90[4]:161–213), and in Lemm (2006. Field Guide to Amphibians and Reptiles of the San Diego Region. University of California Press. Berkeley, California).

We extend our thanks to Mark R. Jennings for making useful comments on this manuscript, and Carlton Rochester, Drew Stokes, Gale Bustillos, and Yolaine Stout for providing additional information for Alpine locations, and Kyle Icke, Rick Roedell, and Jim Davidson for the Ramona location.

Submitted by **EDWARD L. ERVIN**, Merkel and Associates, Inc., 5434 Ruffin Road, San Diego, California 92123, USA; and **TIMOTHY R. BURKHARDT**, 49 Blossom Lane, San Rafael, California 94901, USA.

AMBYSTOMA TIGRINUM TIGRINUM (Eastern Tiger Salamander). **BURROW DESCRIPTION.** Relatively little is known about burrows of the Eastern Tiger Salamander (Semlitsch 1983. Can. J. Zool. 61:616–620; Madison and Ferrand III 1998. Copeia 1998:402–410; Gruberg and Stirling 1972. Herpetol. Rev. 4:85–89). During winter 2005, we radio-instrumented four *A. t. tigrinum* as they exited a breeding wetland in southwest Georgia, USA. In all instances, animals were tracked to underground burrows with one or more visible entrances. The area and depth of burrows were measured when we attempted to recover the transmitters; measurements varied considerably among individuals.

One radio-tagged female was located in a burrow seven days after release. The burrow was adjacent to an agricultural field and firebreak, and was 6 m from the base of a large live oak, *Quercus virginiana*. The burrow meandered through an area ca. 0.5 × 0.50 m and reached a maximum depth of 0.30 m. Only one entrance was found; the burrow terminus was an elliptical cavity.

A tagged male was also located seven days after release. It spent two days in a shallow, branched burrow network. Total burrow length was ca. 4 m with a total area of 1.0 × 3.5 m. Although most of the tunnels were shallow, the burrow reached a maximum depth of 0.20 m. There was no tree canopy over the burrow system and

Herpetological Review

The Quarterly News-Journal of the Society for the Study of Amphibians and Reptiles

Society for the Study of Amphibians and Reptiles

www.ssarherps.org

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

Annual Dues and Subscriptions: Annual membership dues for the year 2007 in the Society for the Study of Amphibians and Reptiles are as follows: **REGULAR** membership US$60 (Student $30)—includes *Journal of Herpetology* and *Herpetological Review*; **PLENARY** membership US$80 (Student $45)—includes *JH*, *HR*, and annual subscription to the *Catalogue of American Amphibians and Reptiles*; **INSTITUTIONAL SUBSCRIPTION** $115—includes JH and HR. Additional fee for airmail postage outside USA $35 for one year. Additional membership categories available on the SSAR webpage: http://www.ssarherps.org/pages/membership.html.

All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with Visa or MasterCard (account number and expiration date must be provided). Payment should be sent to: Breck Bartholomew, SSAR Membership Office, P.O. Box 58517, Salt Lake City, Utah 84158, USA. Fax: (801) 453-0489; e-mail: ssar@herplit.com.

Future Annual Meetings

2007 — Saint Louis, Missouri, 11–16 July (with ASIH, HL)
2008 — Montreal, Canada (with ASIH, HL)
2009 — Portland, Oregon (with ASIH, HL)

About Our Cover: *Dicamptodon ensatus*

The Pacific Giant Salamanders (genus *Dicamptodon*), are a phylogenetically isolated group, assigned to their own family (Dicamptodontidae). For many years, *Dicamptodon* was thought to consist of but a single species (*D. ensatus*) occupying the humid coastal forests from central California to the Pacific Northwest. The first indication of greater diversity was the discovery and description in 1970 of *Dicamptodon copei*, a small, neotenic species restricted to western Washington and extreme northwestern Oregon (Nussbaum 1970. Copeia 1970:506–514). Later, allozyme studies by Daugherty et al. (1983. Copeia 1983:679–691) and Good (1989. Evolution 43:728–744) revealed that the formerly wide-ranging *D. ensatus* was comprised of three species-level groups: *D. aterrimus*, *ensatus*, and *tenebrosus*.

Our cover subject is an example of an adult *D. ensatus* (California Giant Salamander), the southernmost member of the group. This species occupies a small area of coastal California from the Santa Cruz Mountains north to southern Mendocino Co., closely associated with humid forests. Its range narrowly (by about 2.5 km) overlaps that of its northern relative *D. tenebrosus*, and hybrids between these two species are known (Good, *op. cit.*). This is one of the largest terrestrial salamanders, up to 304 mm TL. Adults are occasionally seen surface active on rainy nights, but more often can be observed at burrow entrances adjacent to small streams at night. Eggs, numbering 70–100 per female, are laid underground in running water, and attended by the female until hatching. The larval period ranges from 2–3 yrs. Paedomorphic individuals are known from the southern part of the range, and are associated with underground cave systems. Of the four species of *Dicamptodon*, *D. ensatus* is the only one known to emit bark-like vocalizations when roughly handled. Two thorough reviews of the natural history of this species have been published recently, and this account draws largely from those works: Fellers and Kuchta (2005. *In* Jones et al. [eds.], Amphibians of the Pacific Northwest, pp. 50–53. Seattle Audubon Society) and Bury (2005. *In* Lannoo [ed.], Amphibian Declines: The Conservation Status of United States Species, pp. 653–654. Univ. California Press, Berkeley).

Brian Freiermuth photographed the cover salamander in late February in California's Santa Cruz Mountains, the southern terminus of this species' range. The photo was taken using a Nikon D70 digital SLR camera with a 24mm fixed lens mounted on a Benbo Trekker tripod with wireless remote trigger. The image was recorded using natural light with fill flash (SB800) stopped down 2 exposures. A long exposure (4 seconds) captured movement of the stream. Brian is an avid naturalist and photographer. The majority of his coverage is herpetofauna, both wild and captive. Currently he works as an environmental consultant in the San Francisco Bay Area, performing a wide range of field studies. With an undergraduate degree in Earth Systems Science and Policy, he plans to return to school to seek a PhD in biology (with a focus on herpetology).

SSAR BUSINESS

Open Letter to Membership

SSAR will celebrate its 50th Anniversary in 2007. Special activities will take place during the Joint Meeting of Ichthyologists and Herpetologists (JMIH) in St. Louis, 11–16 July. The major events associated with SSAR's Anniversary are scheduled for 13 July. These events feature a symposium organized by Jonathan Losos entitled "Herpetology in the Age of Genomics." Jim Murphy and Kraig Adler will be the Masters of Ceremonies for a special SSAR Banquet that evening. The SSAR/HL auction will follow the banquet. And, of course, everyone is invited to attend the Business meeting on July 15. A link to registration on our website (http:www.ssarherps.org) will be available in January. Registration can be for the entire meeting or only for the day of the SSAR celebration.

—Robin Andrews, SSAR President

Annual Report (2006) Grants-in-Herpetology Committee

An award in the amount of US $500 was made to each of the following individuals:

Conservation.—**Ricardo J. Torres-Cervantes**, Oklahoma State University. Project title: "Conservation and disease in the endangered aquatic Patagonian frog (*Atelognathus patagonicus*) and other Patagonian frogs."

Field Research.—**Dean A. Croshaw**, University of New Orleans/Savannah River Ecology Laboratory. Project title: "Polyandry in *Ambystoma talpoideum* and its consequences for individuals and populations."

Laboratory Research.—**Matthew Chatfield**, University of Michigan. Project title: "Hybrid zone dynamics between two species of salamanders in the genus *Plethodon*."

Travel.—**Ali M. Rabatsky**, University of Louisiana at Lafayette. Project title: "Evolutionary vestigialization of complex features using an island rattlesnake model."

International.—**Juan Carlos Jordån Arizmendi**, Universidad Nacional Mayor de San Marcos, Peru. Project title: "Resource partitioning among three sympatric *Ameiva* lizards (Sauria: Teiidae) in the Zona Reservada de Tumbes (Tumbes, Perú)."

2006 Grants-in-Herpetology Committee.—Chair: Erik R. Wild. Reviewers: Jeffrey Parmelee, Carol Spencer, Tod Reeder, James Austin, Chris Parkinson. SSAR congratulates the 2006 GIH recipients and thanks the committee members for their efforts.

Grants-in-Herpetology 2007 Proposals

Proposals are now being accepted for the 2007 SSAR Grants-in-Herpetology Program. This program is intended to provide financial support for deserving individuals or organizations involved in herpetological research, education, or conservation. Applica-

tion deadline is 28 February 2007. Grant application details are available at:

<http://www.ssarherps.org/pages/GIH.html>

Manuscript Review Service: An Update and Reminder

SSAR has a service for herpetological researchers, who wish to publish in English, but do not have English as their first language. As a society we offer some assistance to such authors in editing their manuscripts *before* they submit them for publication. This service has proven popular and we'd like to remind both authors and potential pre-submission reviewers about the program. Information about this service is posted at http://www.ssarherps.org/pages/presub.php

As a potential author, look over carefully what is mentioned at that website, and feel free to contact researchers listed at that site, if you feel they can help you with your manuscript. If you are already listed on the site as a potential reviewer, please confirm that the information there is current.

It would be nice to expand the list of potential reviewers. Therefore, if you are comfortable with your English skills and would like to be added to the list of potential reviewers, please consider doing so. The contact information and what is required to be a potential reviewer is provided at that website.

2006 Annual Meeting, New Orleans, Louisiana

The 49th annual meeting of SSAR took place from 12–17 July, 2006 at the Sheraton Hotel in New Orleans, Louisiana. SSAR members met with members of the American Elasmobranch Society (AES), the American Society of Ichthyologists and Herpetologists (ASIH), and The Herpetologists' League (HL). The meeting was co-hosted by the University of New Orleans (UNO), Southeastern Louisiana University (SELU), and Tulane University with local hosts Hank Bart, Bob Cashner, and Brian Crother.

A total of 1206 herpetologists and ichthyologists from 30 countries (including Argentina, Australia, Brazil, Costa Rica, Ecuador, Italy, Jamaica, Japan, Mexico, and New Zealand) attended the meeting. Approximately 530 of those present were students and around 590 papers and 280 posters were presented. Seven symposia, including one sponsored by SSAR (Amphibian and Reptile Use of Golf Courses, organized by Peter Paton and David Scott), were included in the meeting schedule.

SSAR extends thanks to the local co-hosts and other members of the Local Committee (especially the graduate students) for all of their hard work. We are once again very grateful to Sharon Brookshire and the staff of the Kansas State University Division of Continuing Education for a very smoothly-run meeting.

Social Programs and Resolutions

On the evening of 12 July, President Robin Andrews introduced Dr. Aaron Bauer (Villanova University) who gave this year's well-received SSAR President's Travelogue "Herps and Herping in India and Sri Lanka." Aaron continued the tradition of enjoyable and informative Travelogues. With around 1500 species of reptiles and amphibians in India and Sri Lanka, there are plenty of opportunities for study—even if some of them involve wearing a sarong and getting to a field site on the back of a camel! Many species of herps are poorly known in this part of the world. For example, in the Eastern Ghats of India, the leaf-toed gecko was first described in 1870 and then not observed again until 1985. As could be expected, geckos featured prominently in Aaron's presentation. We saw beautiful pictures of colonial golden geckos. Only the dominant males are golden and they appear to use cracks in boulders as resonating chambers for their vocalizations. In addition to lots of herp pictures, we also saw slides of people and places including impressive archeological sites and regions in eastern Sri Lanka that were devastated by the 2004 tsunami.

The next morning, the meeting officially began with a call to order by the local co-hosts. Bob Cashner on behalf of UNO welcomed us to the city and to the JMIH. An invitation to hold the 2006 meeting in New Orleans was offered in 2001. This was intended as the 10-year anniversary of the 1996 New Orleans meeting. Following Hurricanes Katrina and Rita, the local organizers and Meeting Planning Committee seriously considered other venues (including holding the meeting in Tampa again). Bob (whose home was flooded and was completely gutted recently in anticipation of renovation) recounted that, towards the end of 2005, they were "inundated" with letters of support from society members who wanted to hold the 2006 JMIH in New Orleans if at all possible. Brian Crother and Mary White (both from SELU) were key players in moving things forward and by December of last year it appeared that the New Orleans meeting would go ahead. The key to success, according to Bob, was that the three sponsoring universities worked together closely. Bob said that the city desperately needs conferences like this, both to support the local economy and to serve as "ambassadors" to help tell the story of what happened in New Orleans and of the current situation. Hank Bart (Tulane University) and Brian Crother echoed Bob's welcome and thanked members of the societies for their many well-wishes. Brian mentioned that Mary White, for all her efforts, should be considered a fourth co-host. Drs. Scott Cowen (President, Tulane University) and John Crain (Provost, SELU) then greeted the

President Andrews thanking Aaron Bauer for his presentation of the 2006 President's Travelogue "Herps and Herping in India and Sri Lanka." Photograph by Marion Preest.

meeting attendees and made introductory comments.

The warm welcome we received throughout the week from the co-hosts and meeting organizers, the hotel staff, and locals in restaurants, shops, and along the streets was unrivalled in my experience. If you missed this meeting, you really did miss something special! Many people at the meeting expressed a feeling of satisfaction and pride at being members of Societies that contributed (even if in a small way) to helping New Orleans get back on its feet. Mary White arranged an opportunity for those who could arrive a day early to assist with Habitat for Humanity's vast efforts in New Orleans. There is no shortage of work to be done! Bob Cashner, Hank Bart, and President Cowen all encouraged those at the meeting to take advantage of the "Hurricane Tours" being offered twice daily by Liz Sigler, Meg O'Connell, and Jim Grady (all from UNO). The tours quickly filled up following this encouragement and many were over-booked. The tour consisted of a 3-hour drive through a small part of the hardest hit areas of the city. Despite all the news coverage last August and September, I think all of us were struck by the magnitude of the damage and the vastness of the area affected (even though we only saw a minor fraction of it). Many people's memories of the 2006 JMIH will not be of papers attended or posters viewed, but of the devastation still so apparent almost a year after the 2005 hurricane season.

Following the call to order and welcomes on the first morning, the Plenary Sessions began. Daryl Frost (President, ASIH) introduced Dr. Lynne Parenti (Past-President, ASIH) who gave a presentation entitled "A Sense of Scale." This was followed by Dr. H. Carl Gerhardt, the Herpetologists' League Distinguished Herpetologist for 2006 who spoke on "Evolution and Mechanisms of Accoustic Communication in Frogs and Toads" and Dr. Robert A. Thomas from Loyola University who presented "How do Severe Storms affect the Herpetofauna? Louisiana is Alive and Croaking." A busy schedule of paper sessions and symposia began on the afternoon following the Plenary Session.

That evening the group photograph was taken outside on the steps of the Aquarium of the Americas. Following this, a reception was held in the Aquarium, which had only recently reopened following Hurricane Katrina.

In contrast with the previous two years, this year's Annual Picnic was not disrupted by weather and was held at the Audubon Zoo as planned. Attendees congregated on the patio area of the Swamp Exhibit and enjoyed good food, live music, and the heat and humidity of New Orleans outdoors in July.

Over $4,400 was raised at the Annual SSAR/HL Live Auction held on Sunday evening. SSAR uses these funds to support Student Travel Awards. Daryl Frost served as the auctioneer. The silent auction held throughout the meeting raised $462 (also used to support student travel).

The Annual Banquet was held in the Sheraton Hotel on 17 July with Larry Allen serving as the Master of Ceremonies. Past-Presidents of ASIH, SSAR, HL, and AES in attendance at the banquet were acknowledged. HL and ASIH presented a number of awards including the Storer and Stoye Student Awards and the H.S. Fitch Award to Whit Gibbons. Henry Mushinsky (Past President of SSAR) was informed of his election as President-Elect of ASIH. He will join the small but select group of herpetologists who have been President of SSAR, ASIH, and HL.

The following SSAR resolutions, prepared by Richard Wassersug (SSAR Resolutions Chair), were read:

Whereas, the following individuals have given freely of their time, energy, and expertise to SSAR, and

Whereas, because of their hard work and dedication, SSAR programs, projects, and goals have been advanced, and,

Whereas, SSAR is dependent on the generosity and tremendous efforts of its members and is grateful for their willingness to serve,

Therefore be it resolved that the Society for the Study of Amphibians and Reptiles offers its gratitude and sincere thanks for jobs well done to the following individuals:

Theodora Pinou, Treasurer (2001–2006); Brian Sullivan, Editor, *Journal of Herpetology* (2001–2005, now serving as Associate

Editor to help with the editorship transition); Bill Parker, Managing Editor, *Journal of Herpetology* (1991–2005): Don Forester, Associate Editor, *Journal of Herpetology* (2002–2005); Andrew Price, Associate Editor, *Journal of Herpetology* (2005); Martin Whiting, Associate Editor, *Journal of Herpetology* (2002–2005); Erik Wild, Associate Editor, *Journal of Herpetology* (1997–2005); Steve Johnson, Associate Editor, *Herpetological Review* (2004–2005); Paul Stone, Associate Editor, *Herpetological Review* (2000–2005); Hidetoshi Ota, Geographic Distribution Section Editor, *Herpetological Review* (1996–2005); Hugo Alamillo, Copy Editor, *Herpetological Review* (2002–2006); Robert Gatten, Jr. Chair, Kennedy Award Committee (1988–2005, chair since 1999); Linda Ford, Chair, Resolutions Committee (2004); Marion Preest, Chair, Henri Seibert Awards Committee (2001–2005); Jack Sites, Member, Standard English and Scientific Names Committee; Chris Tracy, Nominations Committee (2004–2005).

The Banquet closed with thanks from Larry Allen to the Local Committee and conference organizers and an enthusiastic invitation to attend the 2007 Joint Meeting in St. Louis, Missouri (11–16 July).

Board Meeting and Business Meeting Summaries

Society President Robin Andrews called the Annual SSAR Board Meeting to order at 0805 h on 12 July 2006 in the Sheraton Hotel, New Orleans, Louisiana. In attendance were 7 members of the Board of Directors and 15 Editors, Committee Chairs, or members of the Society. Minutes of the 2005 Board of Directors Meeting (Tampa, Florida) were approved.

Annual reports for 2006/2007 were submitted by all officers, editors, and committee chairs. In her past year in office, President Andrews (with the assistance of the Secretary) reported revising the *SSAR Constitution* and updating *Organization, Functions, and Duties of the Officers, Editors, and Committees*. Both documents are now accessible via the SSAR website. She also wrote descriptions of the Society and of the *Journal of Herpetology* for the JSTOR website.

President Andrews appointed Richard Wassersug as Chair of the Resolutions Committee, Lynette Sievert as Chair of the Kennedy Award Committee, and Margaret Gunzburger and Lora Smith as co-Chairs of the Henri Seibert Award Committee. Thanks to Linda Ford, Bob Gatten, Jr, and Marion Preest who previously served in these positions. She wrote letters of thanks to the local committee who hosted the 2005 JMIH in Tampa and letters of congratulations to the winners of the Grants-in-Herpetology Awards. President Andrews suggested that the President's Fund (to which Presidents contribute $500 at the end of their term) be phased out after she steps down, however this proposal was not supported by the Board.

President Andrews attended several meetings in Tampa to discuss proposals by the Alliance Communications Group to publish *Journal of Herpetology*. She decided that the proposal to publish was not favorable, however a number of other services offered by the group were attractive. President Andrews noted in her report that SSAR is still searching for a permanent repository for its archives. The National Museum was raised as a possibility. President-Elect Roy McDiarmid will investigate this possibility. He requested that he be informed as to the volume of material needing archiving. Aaron Bauer was invited to present the President's Travelogue at the 2006 JMIH.

Treasurer, Theodora Pinou reported that during 2005, SSAR's expenses exceeded revenues resulting in an operating loss of $24,315. However, the Society realized investment income of $26,204 (a 4% return on investments) and received a grant of $33,600 and a donation of $4,776 that resulted in a net income of $40,265. Early in 2006, the portfolio of mutual fund investments was reshuffled to enhance income while maintaining the Society's investment objective of maximizing returns on investment while preserving the original principal amount of all restricted funds.

An overall decline in membership through 2005 may be partly explained by the availability of past SSAR publications through BioOne. Individual memberships however, increased in 2006 at least partly due to a concerted effort to contact members who had not renewed in recent years. Breck Bartholomew suggested that SSAR consider a membership drive in association with our 50th Anniversary Celebration in 2007. Dick Durtsche mentioned that he talks to members of his herpetology class about SSAR, points them in the direction of the website, and provides them with membership application forms.

Treasurer Pinou reported that SSAR received royalties of $10,006 (2004) and $12,426 (2005) from BioOne. Duties of the membership office were transferred from the Treasurer to the Publications Secretary's office in 2005.

Among her duties in the past year, Secretary Marion Preest reported that she wrote a summary of the 2005 Annual Meeting and compiled the Annual Report and prepared agendas for the Board and Business Meetings at the 2006 Annual Meeting. She responded to numerous emails regarding SSAR business and updated SSAR letterhead and various pages on the website.

Publications Secretary, Breck Bartholomew reported that income from sales of the Society's publications totaled $33,187. Members now receive a 10% discount on all SSAR publications and approximately a 20% discount for prepublication sales. Breck is investigating the possibility of having a distributor handle SSAR publications in Europe. Even with extra costs of shipping and han-

Steve Secor and Vic Hutchison enjoying the General Reception at the newly-reopened Aquarium of the Americas. Photograph by Marion Preest.

dling, he predicts the Society would still realize a profit.

Andy Price, Editor of *Catalogue of American Amphibians and Reptiles* (*CAAR*), reported that because of problems during the editorship transition, the 2005 account was delayed until February, 2006. It consisted of 20 accounts. The 2006 account (also 20 accounts) is expected this year. Andy is searching for new mapping software for account range maps. There was some discussion among those at the Board meeting of GIS systems and ArcView.

Kraig Adler (Editor) reported on the publication activities of *Contributions to Herpetology*. No books were published in 2005. "*Biology of the Reptilia*, Volume 20 (Morphology)," edited by Carl Gans, Abbot Gaunt, and Kraig Adler is anticipated for December 2006. Volume 21 (a complete bibliography of previous Volumes) will be the last in this series. Formatting has begun on "*Tasks and Problems Studying the Life of Reptiles in Zoos,*" by Hans-Günter Petzold. Publications beyond 2006 include "*Herpetological Time Travel Through the Zoo and Aquarium World*," by James B. Murphy, "*Contributions to the History of Herpetology*," Volume 2, "*Field Guide to Amphibians and Reptiles of the West Indies*," by S. Blair Hedges, and "*Lizards of Southern Africa*," edited by William R. Branch and Aaron Bauer. *Contributions to Herpetology* is a sequel to the 1989 volume issued at the First World Congress of Herpetology and will include biographies of leading herpetologists, an index to taxonomic authors, and doctoral lineages.

Editor of *Facsimile Reprints in Herpetology*, Aaron Bauer, reported that "*The Herpetological Contributions of Mario Giancinto Peracca*," edited by Franco Andreone and Elena Gavetti (with an English translation of the introduction) will be published in 2006. A donation has been received from the Societas Herpetologica Italica in support of this book. Planned for 2007 is "*Gray's Catalogues of the Specimens of Amphibians and Reptiles in the Collection of the British Museum.*" Aaron mentioned another organization publishing herpetological reprints. He does not view them as serious competition however as they are publishing facsimiles of mostly 20th century works.

John Moriarty (Editor, *Herpetological Circulars*) reported that "*Synopsis of Helminths Endoparasitic in Snakes of the United States and Canada*" has been printed and "*A Review of Marking Techniques for Amphibians and Reptiles*" is anticipated in late 2006. Two *Circulars* are planned for 2007 including "*The First Fifty Years – A History of SSAR.*" John suggests having this distributed *gratis* at the 2007 JMIH.

P. Steven Corn (former Editor, *Herpetological Conservation*) reported that Volume 2, "*Ecology, Conservation, and Status of Reptiles in Canada*," is at the page proofs stage and should be ready for publication in late September. Robin Jung and Joe Mitchell, current co-Editors of *Herpetological Conservation*, reported that they have received 52 submissions for Volume 3 "*Urban Herpetology: Ecology, Conservation and Management of Amphibians and Reptiles in Urban and Suburban Environments.*" These are in various stages of completion and revision. The editors plan to approach a publisher in early Fall, 2006. The U.S. Forest Service has provided a donation to assist with publication costs.

Herpetological Review Editor, Robert Hansen reported a 13% increase in the number of pages in *Herpetological Review* Volume 36 compared with Volume 35. To deal with a backlog of accepted natural history notes, more space was devoted to that section in Volume 36. The time lag for publication is now 3–9 months. The rate of new submissions appears to have leveled off. Most manuscripts are submitted and handled electronically. The SSAR Manuscript Review Service continues to be used. A Board member suggested that this service may need updating. Steve Johnson and Paul Stone (Associate Editors), Hidetoshi Ota (Geographic Distribution Section Editor), and Hugo Alamillo (Copy Editor) have resigned. New appointments include Brent Thomas, Indraneil Das, and Raul Diaz. There was discussion among the Board of increasing the amount of color used in *Herpetological Review*.

In 2005, the editorial office of *Journal of Herpetology* received 236 manuscripts (comparable with numbers received annually in the past 5 years). The rejection rate was approximately 60%. All manuscripts received since the beginning of 2006 have been submitted via AllenTrack and this appears to shorten the time for the review process. The median number of days to the first decision on a manuscript is now 32 days. Geoff Smith (Editor) has recom-

Lora Smith and Kirsten Nicholson—meeting burnout! Photograph by Marion Preest.

mended that the Copy Editing and Managing Editing duties be transferred to Allen Press. He provided a description of the services provided by Allen Press. The Board indicated that a decision regarding this should be made by Geoff. There was discussion among Board members of the Author Assistance Program offered by SSAR. It was suggested that a reference to this service be included in the *Instructions to Authors* for the *Journal of Herpetology* and also that editors should ask reviewers to take a more active role in editing manuscripts.

Geoff Smith took over as *JH* Editor in January 2006 and former Editor Brian Sullivan assumed a position as Associate Editor to help with the transition. Bill Parker stepped down as Managing Editor. Don Forester, Andy Price, Martin Whiting, and Erik Wild resigned as Associate Editors and Paul Andreadis, Sarah Bouchard, Tiffany Doan, Walter Meshaka, Matthew Parris, Gad Perry, and Fred Zaidan joined the staff as Associate Editors.

The 50th Anniversary of SSAR will be celebrated at the JMIH in St. Louis, Missouri, 11–16 July 2007. The "Committee on Celebration of the 50th Anniversary of SSAR" (Al Savitzky, Chair) met in Tampa in 2005 to discuss ideas for the celebration. The Joint Meeting Planning Committee will be asked to assist in elevating the profile of SSAR in St. Louis. Two specific ideas for the meeting have been discussed. The first is a symposium on molecular approaches to research on amphibians and reptiles, which provides a link to a symposium held during the 25th Anniversary. The Board voted and agreed unanimously to use the President's Fund to support this symposium and other activities proposed by the Committee. The second idea is a revival of the popular Herp Quiz, which has not been held for a number of years. The Committee met during the 2006 JMIH to discuss additional ideas and welcomes input from Society members. The Board discussed the possibility of a presentation of the history of the Society (focusing on the Society rather than on herpetology in general) possibly instead of the Travelogue or perhaps preceding the SSAR/HL live auction or an SSAR banquet.

Stephen Richter (Chair, Conservation Committee) reported that in 2005 the committee responded to various herpetological queries received from individuals and began forming connections with other herpetological conservation committees. They met with the ASIH Conservation Committee during the 2005 JMIH.

The Dean Metter Memorial Award screening committee (Joseph Beatty, Anne Maglia, and Brian Miller) received 10 proposals for the fourth Dean E. Metter Award. An award was made to Cybil Nicole Smith for her proposal "The Significance of the Distinctive Color Pattern and Behavior of Hatchling Great Plains Skinks (*Eumeces obsoletus*)." Ms. Smith is the first undergraduate to win this award.

Forty-six proposals for the Grants-in-Herpetology program (Erik Wild, Chair) were received in 2006 and awards of $500 were made in each of five categories (Conservation, Field Research, Laboratory Research, Travel, International). The Bibliographic Research category is no longer offered. The vast majority of proposals and letters of recommendation are now submitted electronically.

Marion Preest (Chair, Henri Seibert Awards Committee) reported that awards were made at the 2005 Tampa meeting in the following four categories: Ecology, Physiology/Morphology, Evolution/Systematics, and Conservation.

Catherine Bevier (Chair, Herpetological Education Committee) reported activation of the Herpetology Hotline question/answer page in November 2005. Approximately 50 inquiries were received in the first 6 months of operation. Some of these will be posted to a FAQ page. As requested at the 2005 Board meeting, the Committee is updating the International Grants Programs list on the website. The Board asked that the HEC update the "Careers in Herpetology" webpage.

Lynette Sievert (Chair, Kennedy Student Award Committee) reported that the winner of the 2006 Kennedy Student Award is Margaret Gunzburger for her paper: Gunzburger, M.S. and J. Travis. 2005. Critical Literature Review of the Evidence for Unpalatability of Amphibian Eggs and Larvae. *Journal of Herpetology* 39:547–571.

SSAR had previously agreed to meet as part of the JMIH in St. Louis in 2007 and Montreal in 2008. Henry Mushinsky (SSAR Rep., Meeting Planning Committee [MPC]) reported that the MPC had received and reviewed invitations for future joint meetings. The Board voted to approve meeting in Portland, Oregon in 2009, Providence, Rhode Island in 2010, and Minneapolis, Minnesota in 2011. As at previous Board meetings, there was some discussion of meeting with the World Congress of Herpetology (WCH). The consensus was that, given the prior planning (often several years in advance) now needed for JMIH, SSAR was unlikely to be able to make a commitment to meet with the WCH unless the Congress organizers began planning well in advance of a Congress. A suggestion was made that WCH be invited to participate in the 2009 or 2010 JMIH.

The 2006 JMIH was the first meeting subject to the limit of 700 oral presentations. However, because fewer than 700 abstracts were received, all those who wished to present oral papers were allowed to do so. Every symposium supported by at least one of the four societies was approved for the 2007 meeting. The Board was reminded of the new timetable and procedures for symposium approval.

No election was held in 2005. Kirsten Nicholson (Chair, Nominations Committee) reported that in 2006 the following positions need to be filled: President-Elect, Treasurer, Secretary, Regional Society Board Member, Conservation Board Member, and Regular Board Member (two positions). A new procedure will be implemented in 2006 to allow the Elector to track voters and to ensure confidentiality of votes. There was discussion of converting the Regional Society Board position to a Regular Board position, however, it was decided to retain this position as is for at least another term. It was recommended that the Regional Society Board member reach out to large, active local herpetological societies and encourage them to provide information about SSAR in their newsletters and websites.

Resolutions were read at the 2005 meeting in Tampa by Richard Wassersug thanking retiring members of SSAR for their service and acknowledging Janalee Caldwell and Laurie Vitt for their joint presentation of the SSAR President's Travelogue. Richard questioned whether SSAR should continue to make joint resolutions with ASIH. The Board stated that the Resolutions Chair need not contribute to the joint resolutions unless he/she wished.

Brian Crother (Chair, Standard English and Scientific Names Committee) reported that the committee is in the early stages of producing a new volume of standard English and scientific names. He questioned whether publishing the list as part of the *Herpeto-*

logical Circulars series created a static document and raised the possibility of issuing the next volume in both hard and electronic versions. The Board discussed creating an electronic "living" document, for example a pdf file that could be updated regularly. They decided that the Names Committee and John Moriarty (Editor, *Herp. Circulars*) should choose the appropriate format for the list. The consensus was that no restrictions should be placed on access to the list and that providing the list should be viewed as a service to the wider herpetological community.

Dawn Wilson reported that twenty applications were received for Student Travel Awards and ten awards ($200 each) were presented at the Business Meeting in Tampa. Very few applications were received for the 2006 meeting; Dawn attributed this partly to difficulties with advertising these awards on the meeting website. The possibility of emailing students and alerting them to the existence of the awards was raised.

The Web Oversight Committee (Anne Maglia, Chair) worked with the Relations with Herpetologists at Zoological Parks Committee to launch a new forum (see below). The site is being continually modified and updated and the Committee wishes to thank the webmaster Zack Walker for his hard work and dedication. Suggestions regarding the website are welcomed.

Recent activities of the Relations with Herpetologists at Zoological Parks Committee (Clay Garrett, Chair) include the launching of a committee web page and discussion forum. A bibliography of published contributions by zoo herpetologists will soon be accessible on the web forum. In 2006, the committee plans to explore the idea of a quarterly committee electronic newsletter.

In the past year, Al Savitzky attended both the American Institute of Biological Sciences (AIBS) and BioOne meetings. AIBS has a diverse array of programs and services available. Those of greatest interest to SSAR relate to education and public policy. For example, AIBS is heavily involved in defense of education concerning evolution in public schools and a Fall 2006 workshop organized by Marvalee Wake will cover the issue of macroevolution. AIBS is also concerned with building diversity in the workforce of professional biologists and has a Diversity Scholars Program offering funding for students of under-represented groups to present research at national meetings of member societies (such as SSAR). The public policy office continues to provide advice to lawmakers regarding issues of interest to organismal biologists and ecologists, e.g. funding at NSF, science education, environmental legislation, support of museum collections. AIBS has indicated a willingness to assist member societies with issuance of press releases. AIBS, in collaboration with several other scientific organizations, has designated 2009 as the "Year of Public Understanding of Science."

Al reported that BioOne has a new business model of providing replacement rather than supplemental income to society publishers. The size of the BioOne collection has increased, but cost per title has decreased. There is a very high renewal rate among academic library subscribers. BioOne is concerned about overseas distribution and is actively soliciting subscriptions in Europe and Asia. The full BioOne collection is available free to 80 developing countries. The preservation and archiving of electronic files is of concern, and BioOne has entered into agreements with several organizations and services (e.g. LOCKSS), which employ diverse technologies to archive web-distributed journal content. BioOne is planning to offer a second collection of journals beginning in 2007. Rather than expanding the current collection, this alternative will provide additional titles without diluting the current profit-sharing pool among BioOne publishers. BioOne is now able to handle non-standard issues of society journals. Open Access was once again a topic of discussion. The publishing community expects the U.S. government to mandate further open access publishing of federally funded research. Electronic only publication (no print copies) was also discussed.

Dick Durtsche (Symposium Proposals coordinator) received two proposals for symposia for 2007. The SSAR proposal for "Herpetology in the Age of Genomics" was approved by the Meeting Management committee however the SSAR/HL/ASIH proposal "Chemical Ecology" submitted by the ASIH Graduate Student committee was not approved.

After the annual reports were discussed, the Board turned to new business. Two representatives from Allen Press and Alliance Communications Group reviewed the services they could offer to SSAR including journal production, electronic publication, marketing, membership duties, etc. They could generate a restricted access online data base with a real-time directory that would allow members to pay subscriptions electronically, review their own accounts, access member information, etc. Members would be able to update their own mailing information and email addresses. If needed, Allen Press could provide financial and investment services including filing of necessary reports. President Andrews met with the Allen Press reps during the JMIH and a detailed proposal will be considered by the Board at a later date.

Journal of Herpetology became available through JSTOR in February, 2006. There was discussion of two options to make back issues available to all society members. With the *Per User Model*, SSAR would pay $7.50 per individual per yr for members without institutional access to JSTOR or BioOne. Assuming that requests would be few and that most would come from members in developing countries, President Andrews suggested that the society absorb these costs. With the *Usage Model*, JSTOR access would be provided to all members by bundling it with Allen Press membership services. Given our membership numbers, we would receive 180 free downloads and then pay $0.20 for each additional download up to a cap of $2,520 (plus associated Allen Press charges).

The family membership category needs to be reinstated (it appears to have been dropped in 2003 from the possible membership options). This would allow two or more members living at one address to receive one copy of the journals and each have voting rights and all other rights associated with membership.

Hardin Waddle is currently updating the much out-of-date list of officers, editors, and chairs on the website.

The SSAR 2007 budget was approved. There being no further business, the meeting was adjourned at 1345 h.

The Annual SSAR Business Meeting was called to order by President Andrews at 1603 h on 15 July. Approximately 34 SSAR members were in attendance. President Andrews summarized business dealt with at the Board Meeting on 12 July. Winners of the 2006 Kennedy Award, Henri Seibert Student Awards, Grants in Herpetology Awards, and Student Travel Awards were announced. The meeting was adjourned at 1730 h.

—Respectfully submitted by Marion Preest, SSAR Secretary

Metter Award Proposals Sought for 2007

Dean E. (Doc) Metter (1932–2001) was a long-time member of the biology faculty at the University of Missouri-Columbia, where he taught zoology, comparative anatomy, evolution, and herpetology. A believer in putting knowledge to the test in the field, Doc provided frequent opportunities for students to engage in fieldwork. In addition, he frequently assisted his graduate students as they ventured out to collect data.

Doc was a co-founder of the Bobby Witcher Society, the legacy of which is a scholarship fund. For many years, the interest earned served to reward outstanding herpetology students who intended to continue their education and seek a career in vertebrate biology. That fund now serves a similar purpose by honoring Doc's memory while helping to fund the SSAR-administered Dean E. Metter Memorial Award.

Application details are available from the SSAR website:

<http://www.ssarherps.org/pages/metter.php>

SSAR dues for 2007 must be paid no later than 31 December 2006, and proposals must be submitted (postmarked) by 28 February 2007. Proposals should be submitted electronically as email attachments (preferred) or by regular mail. Submit proposals or questions regarding application procedures to the Chair of the Metter Award Committee, Dr. Joseph J. Beatty (e-mail: beattyj@science.oregonstate.edu). Awards will be announced on or around 10 April 2007.

NEWSNOTES

Herpetological Research & Conservation in Ecuador

We are now accepting applications for participants in our Ecuadorian herpetofauna research program for 2007. Participants will gain hands-on experience in Herpetology and Conservation Ecology. We are studying the population ecology and community structure of reptiles and amphibians in imperiled western Ecuadorian ecosystems, which have dwindled to only 2–5% of their historic area. This rate of ecosystem decline, along with the high levels of biodiversity found in the region, prompted Conservation International to designate western Ecuador and parts of neighboring countries a "Conservation Hotspot"—an area in greatest need of study and conservation. We are exploring the last remaining fragments of disappearing forests. Data from our surveying and monitoring studies will lead to sound management decisions on the ground. Due to the high levels of endemism in the region, nearly every new site explored yields species previously unknown to science. In short, we want to find out what life exists there while there is still the chance, and to assist conservation planning in the region to make sure that as much as possible of the biodiversity found there can be saved.

In exchange for trip fees, participants receive all travel within Ecuador, training, room and board, and an experience to last a lifetime. Internships and course credit are available. We have dates available in January, May, and August of 2007. If you or anyone you know might be interested in participating, please see our Web site, www.ReptileResearch.org, for more details.

Slowinski Award Announced for 2006

The Center for North American Herpetology is pleased to announce that the recipient of The Joseph B. Slowinski Award for Excellence in Snake Systematics for 2006 is Todd A. Castoe, of the Department of Biology, University of Central Florida.

On 12 September 2001, the world lost one of its premier biologists, a loss that went virtually unnoticed in the wake of the tragedy that befell the United States the previous day. Joseph Bruno Slowinski, the 39-year old curator of amphibians, turtles, reptiles, and crocodilians at the California Academy of Sciences in San Francisco, died in the jungles of Burma from the bite of a venomous snake. Joe was bitten on 11 September and, despite heroic efforts to save his life by expedition companions and colleagues, succumbed to the effects of the bite the next day. Eventually, the world took notice, and numerous media outlets across the nation and throughout the world chronicled Joe Slowinski's exemplary career, cut so tragically short.

A distinguished committee, comprised of Frank Burbrink (City University of New York, Staten Island), Brian Crother (Southeastern Louisiana University, Hammond), and Robin Lawson (committee chair, California Academy of Sciences, San Francisco), have deemed the paper "Modeling Nucleotide Evolution at the Mesoscale: The Phylogeny of the Neotropical Pitvipers of the Porthidium Group (Viperidae: Crotalinae)" as the most distinguished paper on snake systematics to appear worldwide during 2005. The paper was co-authored with Mahmood M. Sasa and Christopher L. Parkinson, and was published in Volume 37 of *Molecular Phylogenetics and Evolution*.

As senior author of the paper, Todd Castoe becomes the fourth recipient of The Slowinski Award, and will receive a check from The Center for North American Herpetology for US $500 along with a commemorative memento in recognition of his achievement.

Ouachita Mountains Biological Station

The Ouachita Mountains Biological Station is located in the Ouachita Mountains of western Arkansas. The station consists of 380 acres, almost surrounded by the Ouachita National Forest. The terrain is rugged, and includes several springs and streams. Most of the habitat includes oak-hickory forest or mixed pine-deciduous forest. Several mountain tops with rocky outcrops and low flat wet areas are available. Three small ponds and an abandoned slate mine are on the property.

A well-lighted lecture/laboratory building with AC/heat, bathroom, and shower, can comfortably seat 24 at worktables. A small dormitory building has a kitchen, two bathrooms, shower, AC/heat and 10 beds (5 bunk beds). Four additional beds are available in other buildings. Other facilities include good potable water, a pavilion, and some trails for easy access to distant points. The station is available year-round. A web site with some photos is avail-

able at: www.lsus.edu/lsusmus/ombs/. The station is well-suited for small research or teaching groups.

To reserve space for your group contact:

Kansas Herpetological Society Annual Meeting

The Kansas Herpetological Society held its 33rd Annual Meeting at Fort Hays State University in Hayes, Kansas, on November 4–5, 2006. Over 100 participants attended scientific paper sessions presented by scientists and students from across the nation. Featured speakers were James L. Knight, curator of the South Carolina State Museum in Columbia, and Jerry D. Johnson, professor of biology at the University of Texas-El Paso. Both grew up in Salina, Kansas..

David Bender, student at Fort Hays State University, received the 2006 Howard K. Gloyd/Edward H. Taylor Scholarship, honoring the memory of two great biologists with strong ties to Kansas. The 2006 Alan H. Kamb Grant for Research on Kansas Snakes was made to George R. Pisani, Kansas Biological Survey. Henry S. Fitch, University of Kansas, Lawrence, was chosen as the ninth recipient of "The Suzanne L. & Joseph T. Collins Award for Excellence in Kansas Herpetology." Eugene D. Fleharty was installed as the eighth Distinguished Life Member of the Kansas Herpetological Society. Dr. Fleharty is Emeritus Curator of Herpetology at the Sternberg Museum of Natural History, Fort Hays State University. In 2007, the Society will meet at the Topeka Zoo, Topeka, Kansas.

MEETINGS

Meetings Calendar

Meeting announcement information should be sent directly to the Editor (rwh13@csufresno.edu) well in advance of the event.

18–19 January 2007—Declining Amphibian Populations Task Force, California-Nevada Working Group Annual Meeting, Las Vegas, Nevada, USA. Information: http://ice.ucdavis.edu/CANVDecliningAmphibians/DAPTF2007Announcement.htm.

6–8 February 2007—Workshop: Understanding Agriculture's Effects on Amphibians and Reptiles in a Changing World. Sponsored by U.S. Geological Survey's Amphibian Research and Monitoring Initiative, Partners in Amphibian and Reptile Conservation, the Natural Resources Conservation Service, Environment Canada, the Association of Fish and Wildlife Agencies, and Conservation International. St. Louis, Missouri, USA. Information: http://www.umesc.usgs.gov/ag_effects_workshop/workshop.html.

22–25 February 2007—Southeast Partners in Amphibian and Reptile Conservation, Annual Meeting, Chattanooga, Tennessee, USA. Information: http://www.separc.org/.

31 March–1 April 2007—Florida Herpetology Conference (including the 30th Annual All Florida Herpetology Event), Gainesville, Florida. Information: http://www.flmnh.ufl.edu/herpetology/herpsconference/afhc.htm.

16–20 April 2007—First Mediterranean Herpetological Congress, Marrakech, Morocco. Information available from the Congress website: www.ucam.ac.ma/cmh1.

14–18 April 2007—14th ARAV Conference, Association of Reptile and Amphibian Veterinarians, New Orleans, Louisiana, USA. Information: http://www.arav.org/.

20–23 June 2007—31st International Herpetological Symposium, Toronto, Canada. Information: http://www.kingsnake.com/ihs/.

11–16 July 2007—50th Annual Meeting, Society for the Study of Amphibians and Reptiles; 87th Annual Meeting, American Society of Ichthyologists and Herpetologists; 65th Annual Meeting, The Herpetologists' League. St. Louis, Missouri, USA. Information: http://www.dce.ksu.edu/jointmeeting/.

3–6 August 2007—5th Conference on the Biology of Plethodontid Salamanders: Symposium in Honor of David B. Wake. Instituto de Biologia, UNAM and ECOSUR, San Cristobal de la Casas, Chiapas, México. Information: http://www.ibiologia.unam.mx/barra/congresos/salamandra/salamandra.html.

CURRENT RESEARCH

The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, **María del Rosario Castañeda** or **Michele Johnson**; postal and e-mail addresses may be found on the inside front cover.

The current contents of various herpetological journals and other publications can be found at: http://www.herplit.com/contents.

Behavioral Response To Social Cues Determined By Dispersal Status in Lizards

During and after dispersal, dispersing individuals face the costs of survival in unfamiliar habitats, and so they may differ from philopatric (non-dispersing) individuals in phenotypic traits that allow them to assess new habitat suitability quickly. To test this hypothesis, the authors examined behavioral responses of dispersing and non-dispersing yearling common lizards (*Lacerta vivipara*) to the presence of scent-marks from conspecific yearlings. Gravid females (N = 172) were captured from four natural populations and housed in the laboratory, where half were treated with corticosterone (a stress hormone) before they laid their eggs to determine if maternal stress affected dispersal. After hatching, juveniles (N = 816) were marked and released in either an unaltered

site or a site with manipulated (decreased) density, but not in the site of their mother's origin. One year later, 140 juveniles were recaptured and categorized as dispersers or non-dispersers and transferred to the laboratory where they were exposed to each of four conditions: 1) caged with no conspecific scent-marks, 2) caged with odor of one conspecific, 3) caged with odors of three conspecifics housed in isolation, and 4) caged with odors of three conspecifics housed communally. Results showed that morphometry did not differ among dispersers and non-dispersers, and that density, release site, maternal hormone treatment, and sex had no effect on response to the different conditions. However, dispersers spent more time trying to escape from scents from communally housed conspecifics than isolated scents, while the opposite was true for non-dispersers. The authors suggested that this may be an attempt of dispersers to avoid potential conflicts with other interacting individuals during the risky dispersal period. They concluded that while the environmental components measured did not affect dispersal-related behavior, dispersers are more sensitive to novel social cues.

Genetic Differences and Plasticity Determine Diet Preferences in Tiger Snakes

Genotypic and phenotypic variation play major roles in food selection, and environmental variation and differences in dietary experience can result in behavioral plasticity in response to food. As these factors interact, it is difficult to determine their relative importance in feeding behavior. To address this question, the authors studied two disjunct populations of tiger snakes (*Notechis scutatus*) in Australia that occur in environments (mainland vs. island) with different prey availabilities. They tested feeding preferences among 6 types of prey (mouse, skink, silver gull, chicken, shearwater, and frog) in three groups of tiger snakes: wild-caught adults, neonates, and laboratory-reared juveniles. Results from these trials showed that adults ($N = 55$) from the two populations shared preferences for the same types of prey, regardless of their natural diet. Diet-naïve neonates ($N = 82$) showed interest in all prey types, but island neonates preferred gull chicks (the main prey of island adults) more than mainland neonates. Juveniles ($N = 15$) that were fed only mice until 8 months of age significantly preferred mice. The authors concluded that although the species has the potential for behavioral plasticity, the preferences shown by island snakes for prey no longer consumed by their population also indicate a strong genetic basis in feeding behavior for this species.

New Phylogeny and Insights on Biogeographic Patterns of Ranid Frogs

Ranidae is one of the largest extant anuran families, with more than 1000 extant species and a nearly global distribution. However, there is no phylogenetic hypothesis for all major lineages in this group. The authors sequenced ~1570 bp of nuclear gene fragments (*Rag-1*, *Tyr*, and *Rhod*) and ~2100 bp of the mitochondrial genome from 104 species, including representatives of all ranid subfamilies. Parsimony, maximum likelihood and Bayesian analyses were performed to reconstruct the phylogeny, which was used in an attempt to reconstruct the early biogeographic history of the group. The phylogeny indicates that the monophyly of several previously recognized groups is rejected with high confidence. Further, the results of the biogeographic analyses indicate that plate tectonics have played an important role in determining the current distribution of ranids, as each major clade is associated with a single Gondwanan plate and their divergences fit the temporal break-up of the continents. The authors discuss several potential scenarios that would result in the current distribution of ranid frogs.

BOSSUYT, F., R. M. BROWN, D. M. HILLIS, D. C. CANNATELLA, AND M. C. MILINKOVITCH. 2006. Phylogeny and biogeography of a cosmopolitan frog radiation: late Cretaceous diversification resulted in continent-scale endemism in the family Ranidae. Systematic Biology 55:579–594.

Turtle Navigation in Unfamiliar Habitats

Animals may use various orientation mechanisms to locate necessary resources, and different mechanisms are utilized in familiar and unfamiliar areas. Semiaquatic Eastern Painted Turtles (*Chyrsemys picta picta*) are ideal for studies of orientation, as they must travel through risky terrestrial habitat to reach suitable discrete patches of water. To determine whether turtles use an orientation mechanism in unfamiliar areas, the authors removed 60 adult turtles from their home lake and released them on land at five distances (100–2000 m) from an unfamiliar lake. To track paths of movement, each released turtle had a thread bobbin attached to its carapace, and fractal analysis was used to determine the tortuosity (the opposite of straightness) of the trails. Surprisingly, results showed that turtles walked in straight paths, indicating the use of some orientation mechanism, but did not orient towards water or in any single direction. The authors suggested that this implies that the turtles could not locate suitable aquatic habitats, even though they were most likely trying to reach them. They conclude that a compass mechanism (using either the sun or the earth's magnetic field) is the only mechanism that would produce these results, but that in unfamiliar areas the use of a compass without a mental map does not help them to locate water.

CALDWELL, I. R., AND V. O. NAMS. 2006. A compass without a map: tortuosity and orientation of eastern painted turtles (*Chrysemys picta picta*) released in unfamiliar territory. Canadian Journal of Zoology 84:1129–1137.

Multiple Paternity Varies with Nesting Behavior in Sea Turtles

Mating systems can be affected by a number of behavioral, genetic, and demographic factors, all of which may differ between and within species. The authors studied two populations of Olive Ridley Sea Turtles (*Lepidochelys olivacea*) in Costa Rica to examine the frequency of multiple paternity in these populations, one of which displays mass nesting events (i.e., "arribada") and the other displays solitary nesting behavior. They used two highly polymorphic microsatellite markers to determine the number of paternal alleles occurring in hatchlings from the nests of 13 females (20–27 hatchlings per nest) in each of the two populations. Results indicated that multiple paternity is significantly higher for the arribada population (92%, the highest recorded for marine turtles) than the solitary nesters (30%), but analyses with six polymorphic microsatellite loci showed no genetic differentiation between the populations. The authors suggested that the difference in multiple paternity may be due to the differing abundances of individuals in the mating system between the two groups; the extremely large breeding assemblages that occur for the arribada population may cause mating with multiple individuals to be less energetically demanding, and therefore more frequent, than for the solitary nesters.

Jensen, M. P., A. Abreu-Grobois, J. Frydenberg, and V. Loeschcke. 2006. Microsatellites provide insight into contrasting mating patterns in arribada vs. non-arribada olive ridley sea turtle rookeries. Molecular Ecology 15:2567–2575.

Stress Hormone (But Not Androgens) Determine Male Calling Behavior in Toads

The expression of many sexually dimorphic traits is mediated by the effects of gonadal steroids (e.g., androgens). However, these effects can interact with those of stress hormones, including corticosterone (CORT). In this study, the authors investigated the relationship of androgens and CORT in male calling behavior in the Great Plains Toad (*Bufo cognatus*), a species that displays two male mating tactics: males may call to attract mates, or they may attempt to intercept females responding to calling males (a non-calling "satellite" strategy). First, they measured call parameters (i.e., call duration, frequency, amplitude) and hormone levels in callers with ($N = 24$) and without ($N = 35$) satellite males. They found that callers with and without satellites did not differ in call parameters or in their circulating androgen levels, but callers with satellites had lower CORT levels than callers without satellites. When males ($N = 5$) were experimentally treated with CORT, their call durations compared to a control group decreased over time, independent of their androgen levels. Further, in natural choruses CORT was generally negatively correlated with call duration. Finally, to test the prediction that females prefer longer calls (typical of males with low CORT and satellites), preference trials were performed. Twelve females were exposed to digitized broadcast calls of two different durations, and all preferred the longer calls. This is consistent with the hypothesis that satellites choose to associate with low CORT males to increase their mating opportunities. The authors also discuss potential mechanisms underlying the relationship between CORT, androgens, and satellite-caller associations.

Alternative Developmental Trajectories in Extinct Amphibians

Although metamorphosis is a trait widespread in extant amphibians, the evolutionary origin of these morphological transformations remains poorly understood. The recent discovery of fossils of adult specimens of *Apateon gracilis* (Branchiosauridae clade), revealed that individuals in this group (previously known only from larval specimens) underwent extensive morphological metamorphosis during development. This contrasts with other branchiosaurid species, in which development was neotenic: adult forms were merely an extension of the larval trajectory. In this study, the authors examined fossil material to describe the unique features of *A. gracilis* adults and to determine which features characterized the latest stages of development in this species. They discovered that *A. gracilis* experienced major proportional changes in cheek and posterior skull bones, and that up to 8 postlarval ontogenetic events occurred in a small window of developmental time. These results were compared to *A. caducus*, a neotenic branchiosaurid that has a larger body size but lacks the adult features of *A. gracilis*. The authors concluded that metamorphosis was likely correlated with habitat change (i.e., facultative) in Paleozoic branchiosaurids, and that the developmental pathways seen in extant amphibians were already established in this clade.

Speciation in Plethodontid Salamanders

Many biologists struggle with the questions of how many species exist in a given taxon and how to diagnose those species. Using the general lineage species concept, the author examined two sympatric genera of plethodontid salamanders (*Ensatina* and *Batrachoseps*) in California with the goal of recognizing distinct evolutionary lineages that will likely remain distinct. After reviewing the decades of work on species relationships in *Ensatina*, a

well-known ring species complex, the author recommended that, despite its problems, the most appropriate taxonomy of this group is that of a polytypic species, and that adaptive divergence related to predator avoidance is the dominant force behind the differentiation among populations of this group. In contrast, a review of the work on *Batrachoseps* (the slender salamanders) led to the conclusion that this group includes approximately 20 differentiated species that represent a nonadaptive radiation, as their genetic diversification was not accompanied by ecological differentiation. The role of geography in the evolution of these groups was also discussed. The author concludes that careful analyses of the patterns and processes that lead to species formation will not resolve species controversies, but will continue to yield useful discussion.

How Many Species of Dinosaurs Existed?

Quantifying the species diversity in extinct animal groups is a current focus of paleontologists, but no study has yet attempted to determine the total taxonomic richness of both known and still undiscovered nonavian dinosaurs. Here, the authors applied a statistical method called the abundance-based coverage estimator (ACE) using previously published data to account for the deficiencies in the fossil record and to determine whether dinosaurs were declining prior to their ultimate extinction. They estimated the total "discoverable" diversity of dinosaurs to be 1844 genera, only 527 of which have currently been described. A logistic model predicted that 90% of this diversity will be known within 100–140 years. Estimated dinosaur diversity in the late Cretaceous remained steady (even though known diversity declined in this period), indicating that dinosaurs were not in decline in the 10 million years before extinction. This conclusion shows the importance of considering the incompleteness of the fossil record when analyzing fossil evidence. The authors also discussed factors that affect the relationship between true original dinosaur diversity and estimated discoverable diversity.

Insular Body Size Shifts in Rice Frogs

Island populations of reptiles, birds, and mammals have been shown to have different body sizes than their mainland counterparts, but no previous study has found insular size shifts in amphibians. The authors investigated populations of the Rice Frog (*Rana limnocharis*) on seven islands in the Zhoushan Archipelago and on the mainland of China (N > 17 females and 5–9 males per population), and found that island frogs were significantly larger than their mainland conspecifics in both breeding and non-breeding seasons. This insular body size increase was correlated with both increased population density and higher prey availability on islands. However, there was no relationship between body size on islands and variation in prey size, absence of other competing frog species, island size, or distance of islands from the mainland. The authors suggested that the increased density of rice frogs on islands is the result of increased resource availability, and the increased body size is due to the more intense intraspecific competition that occurs in high density populations. Further, they suggested that reduced predation on islands might also be responsible for the observed increased insular densities, and recommended further study to test this hypothesis.

WU, Z., Y. LI, AND B. R. MURRAY. 2006. Insular shifts in body size of rice frogs in the Zhoushan Archipealgo, China. Journal of Animal Ecology 75:1071–1080.

**Present address: Department of Biological Sciences*
State University of New York at Albany, Albany, New York 12222, USA

On 2 August 2006, "Meg" Stewart, professor (emerita) of biology at the State University of New York at Albany (SUNY, University at Albany) and past president of the Society for the Study of Amphibians and Reptiles (SSAR), passed away peacefully at her home on the Helderberg Plateau in the Appalachian uplands of Albany County, New York, after a long battle with pancreatic cancer. Meg is survived by her husband, George E. Martin (Fig. 1A), her brother John M. Stewart, and several nieces and nephews. To those who may not have known Meg closely, the following quotation from a note written to us in the spring of 2005 (about a year before her death) demonstrates her love of the natural world and her optimistic view of life even as her own was in jeopardy. She said: "It is great to have sunshine and flowers; salamanders are breeding (have bred) in my pool and peepers are calling in our marshes. A little merlin sat in our yard all afternoon yesterday and our red fox walked across the yard at 3:00 pm. How could we ever leave this place?"

FIGS. 1A–C (LEFT TO RIGHT). A. Meg Stewart and her husband, George Martin (October 2004). Photo by Ariana N. Breisch. B. Meg with two of her Ph.D. students, Dan Townsend (left) and Larry Woolbright (right) in Puerto Rico in 1990. Unknown photographer. C. Stewart in the field in southwestern New York in 1957 with undergraduate assistant Gary Larson (center) and New York State Curator of Botany, Stanley J. Smith (right). Photo by Thomas H. Watthews.

Meg was well known to many in the herpetological community as she became the first female president of a major herpetological society anywhere in the world, assuming the elected position of president of SSAR in 1979. She was far from a figurehead officer in SSAR. Meg undertook seriously her assignment of leadership, having a personal agenda to reorganize the committee system within the society and to develop an operating manual for officers and editors that described in detail the roles of these positions (she said it was an unbelievable amount of work as she spent all summer writing letters). These operating procedures have provided a lasting foundation for the society, and the committees and chairs she appointed were similarly oriented toward productivity. This accomplishment, and her subsequent election to the presidency of the American Society of Ichthyologists and Herpetologists (ASIH) in 1996, solidifies her position among the well-known leaders in the major professional herpetological societies. In 2005, ASIH awarded her both the Robert K. Johnson Award for excellence in service to the society and the Henry S. Fitch Award for excellence in the study of amphibian and/or reptile biology.

By Meg's own admission, her society work caused her to sacrifice some momentum in working up her long-term data on tropical anurans. This work, as Powell and Henderson (1996) write, propelled her to prominence in tropical biology: "[She] and [her] coworkers (including A.S. Rand and F.H. Pough, and especially D.S. Townsend and L.L. Woolbright [Fig. 1B]), in a series of papers since 1979, have produced exquisitely detailed studies of *Eleutherodactylus coqui* on Puerto Rico. As a result, this particular frog is the best-known of all West Indian amphibians. Furthermore, Stewart's efforts pioneered the now-growing field of ecological studies on West Indian frogs." Meg herself summarized her early years in the Caribbean in a highly prescient natural history with an entertaining narrative of her research (Stewart 2003). Her field studies in the American tropics were preceded by her well-known study of the amphibian fauna in southeastern Africa conducted during a sabbatical leave in 1963–1964 and culminating in her monograph, *Amphibians of Malawi* (State University of New York Press, 1967), in which keys and line drawings (clearly executed by her own hand) of each species, and color photographs of many, are accompanied by full species accounts including records, range, size, general appearance, similar species, color pattern, body features, sexual dimorphism, variation, calls and calling time, breeding time, eggs, and habits and habitat. Thus reflecting Meg's detailed approach as a systematic naturalist, this work "...established her reputation in herpetology" (Langenheim 1996) and may form a baseline of data to evaluate the global extinction crisis affecting amphibians (Mendelson et al. 2006).

Meg was born on 6 February 1927 in rural Greensboro County, North Carolina, where she was raised with her older sister Josephine and brother John on a 100-acre truck farm that produced fruits, vegetables, eggs, and dairy products operated by her parents (with seemingly unending contributions of the children). She entered the Woman's College (now the University of North Carolina at Greensboro) and later the University of North Carolina at Chapel Hill, receiving her Bachelors and Masters degrees in 1948 and 1951, respectively. In June of 2006, the Epsilon chapter of Phi Beta Kappa at UNC-Greensboro elected her as an alumna member in recognition of an extraordinary career as a scientist and university professor. She was a laboratory instructor in biology and instructor in the Evening College of UNC-Greensboro for several years while an undergraduate student, and later taught briefly at Catawba College after receiving her Masters degree. Her doctoral dissertation (Cornell University, 1956) was on the natural history and development of the Northern Two-lined Salamander, *Eurycea bislineata*. A number of Meg's better known scientific papers are listed in an historical perspective that also outlines further aspects of her life's travels, travails, and triumphs (Brown and Breisch 2005).

Meg was initially appointed in 1956 to a full-time faculty position at the New York State College for Teachers at Albany (now the University at Albany) to which she devoted her full professional career. Her position was dedicated to field biology, but, as a woman, she accepted an entry-level salary 20% lower than comparable pay for men. She considered herself a vertebrate ecologist focusing on population and community ecology, and behavior of amphibians. One of her first major projects was a biological survey of the Allegany Indian Reservation and adjacent Allegany State Park (Stewart 1961) (Fig. 1C). Following her work in Africa, she focused her attention to the New World tropics, but she was quite

at home doing regional faunal surveys as well as conducting field studies of the local herpetofauna of the Adirondack Mountains in northern New York. For decades she devoted much of her natural history talents to the Albany Pine Bush, a glacial remnant pitch pine-sand plain community in and around the City of Albany. The latter "backyard" area served as a study site for her numerous class field trips, solidifying her extensive knowledge of the area's flora and fauna that led to her appointment to a state commission charged with management of the system. She was also active in the local chapter of The Nature Conservancy and supported a diversity of environmental causes, including providing expert testimony at hearings.

Numerous undergraduate and graduate students in her courses praised Meg's classroom abilities and field excursions. She was recognized officially as a Distinguished Teaching Professor in the Department of Biological Sciences at SUNY-Albany in 1977, one of about a dozen such select professors holding this prestigious title in the university. After her official retirement in 1997, she was reappointed to take on the rather arduous job of putting the finishing touches of organization on a new graduate program that she and several colleagues had earlier (in 1991) launched, the Biodiversity, Conservation, and Policy masters program (which accepted its first student in 1998). In 2003, she personally made a gift to endow the program through the establishment of the Margaret M. Stewart Graduate Scholarship (BCP program). Gifts in Meg's memory may be made to the University at Albany Foundation with notation to the above fund, and may be sent to Dr. Sorrell Chesin at the foundation, UAB-201, 1400 Washington Ave., Albany, New York 12222, USA.

Acknowledgments.—We are grateful to Kraig Adler for commenting on Meg's instrumental role in SSAR and other aspects of our summary of her life and legacy.

J. Alan Holman (1931–2006)

JAMES H. HARDING
MSU Museum, Michigan State University
East Lansing, Michigan 48824, USA
e-mail: hardingj@msu.edu

J. Alan Holman died suddenly of a heart attack on 12 August 2006 at his beloved fishing cabin at Fife Lake in northern Michigan, ending a remarkable and productive career in vertebrate paleontology and herpetology, and leaving family, friends, and colleagues with a profound sense of loss.

Al Holman, excavating microfossils near East Lake, Mackinac Co., Michigan, July 2002. Photograph by Phil Myers.

Al Holman was born in Indianapolis, Indiana, in 1931, and very early developed an intense interest in the natural world, and amphibians and reptiles in particular. He recalled as a child having a continuous and ever-changing menagerie of the local herpetofauna, and noted that the common species in the area then are now among the rarest, including the Kirtland's Snake (*Clonophis kirtlandii*) and the Cricket Frog (*Acris crepitans*), the latter being once so abundant that he often collected the little frogs as food for his snakes. Years afterward Al often lamented the obvious drastic decline in "herp" species and numbers over his lifetime. "What bothers me most," he would say, "is not that the rarer, more specialized species have become endangered or even disappeared—it's that the formerly common "generalist' species have now become rare—even in places that still seem to have habitat!" Al tried to do something about this situation, but his greatest contributions to science came in studying long-extinct amphibians and reptiles.

Al attended Franklin College in Indiana, receiving his Bachelor of Science degree in 1953. After a stint in the Navy, working as a medical corpsman, he then went on to graduate studies at the University of Florida, Gainesville, earning his MS degree in Biology in 1957, and his PhD in Systematics and Ecology in 1961. Al's doctorate advisor was Dr. Pierce Brodkorb, so not surprisingly his PhD thesis focused on fossil birds ("The osteology of living and fossil New World quail"). Another of his mentors at UF was Dr. Archie Carr, the famous marine turtle expert, who presumably encouraged Al's special life-long appreciation for all things chelonian.

Al began his teaching career at Samford University and then Illinois State University before coming to Michigan State University in 1967, where he had joint appointments in the Geology and Zoology Departments. He taught the undergraduate course in vertebrate paleontology, and later (after the retirement of friend and colleague Dr. Max Hensley) the herpetology course. He also be-

came the first curator of vertebrate paleontology at the MSU Museum. Over three decades, Al amassed a collection of nearly 3000 fossil specimens—mostly fossil fishes, amphibians, reptiles, and small mammals, but also a large mammoth skull he and colleagues collected in Kansas in 1971, now on display at the Museum. In addition, Al prepared and curated an impressive herpetological comparative osteological collection, presently containing over 4100 complete and partial skeletons. During his career, and after retirement, he described 53 new species, 22 genera, and one family of vertebrate fossils.

Al Holman focused his research on Cenozoic and Quaternary paleoherpetology in North America and Europe, and was a leading authority on New World fossil snakes. His studies on disharmonious Pleistocene "herp" faunas lent support for the Pleistocene Climatic Equability Hypothesis (in part, the idea that at times during the Pleistocene, winters were warmer and summers were milder in much of eastern and central North America than occurs today.) He also dabbled in "larger" animals at times, including devising a hypothesis that, post-glacially, mammoths and mastodons migrated to Michigan from other areas to partake of salt deposits in the central lower peninsula. Al enjoyed field work and for many years led expeditions of graduate students to many parts of the United States and Canada, and also worked with colleagues in the United Kingdom. Important fossil sites included sink holes in Florida, sand pits in Kansas and Nebraska, peat bogs in Michigan, and interglacial beds in Norfolk, England.

Al's research produced more than 300 publications, most of which were scholarly papers, but also a number of semi-popular and popular articles, along with eleven books. His productivity certainly did not decline after "official" retirement in 1997. His most recent book is "Fossil Salamanders of North America" (2006); other titles include "Fossil Frogs and Toads of North America" (2003), "In Quest of Great Lakes Ice Age Vertebrates" (2001), and "Fossil Snakes of North America" (2000). His concern for the conservation of living amphibians and reptiles was reflected in the production of three popular educational field guides on Michigan herps that we co-authored: "Michigan Snakes" (revised in 2006), "Michigan Turtles and Lizards" (1990, rev. 1997), and "Michigan Frogs, Toads, and Salamanders" (1992). In 2003, Al and his wife Margaret ("Peg") Holman (a respected archeologist who died in April 2006) co-authored a popular guide to Michigan's natural and human history—"The Michigan Roadside Naturalist." At least two additional book manuscripts were complete or nearly so, and are forthcoming.

Al Holman was foremost a dedicated educator. He chaired the committees of 21 graduate students at the masters and doctorate levels, and served on many others. His students knew him to be a kind and patient advisor, but with high expectations for academic achievement and communications skills. His colleagues knew Al as a reliable friend and confidant, ever willing to offer useful advice or assist with an academic question. A humble and often shy man, but with a droll wit and an uplifting sense of humor, Al's jokes could lighten the mood or break the tension at the driest or most acrimonious of staff meetings.

There can be no regrets for Al Holman's lifetime of contributions to his academic profession, his dedication and love for his family, and the well-earned respect of his colleagues and students. But we lament the untimely loss, and greatly miss his counsel and friendship.

Herpetological Review, 2006, 37(4), 399–400.

Warren J. Iliff (1936–2006)

JAMES B. MURPHY
Department of Herpetology, National Zoological Park
3001 Connecticut Ave., NW, Washington, D.C. 20008, USA
e-mail: jbmurphy2@juno.com

Warren Iliff served as Past-President of the Association of Zoos & Aquariums (formerly American Association of Zoological Parks and Aquariums) while he was director of the Dallas Zoo and Dallas Aquarium between 1984 and 1990. As president, his final position was to design and build the Aquarium of the Pacific in Long Beach, California. Photograph courtesy of the Aquarium of the Pacific.

When Warren Iliff arrived at the Dallas Zoo in Texas as director and my boss in 1984, the place was in shambles—lack of public support and declining attendance, indifferent city officials, an uninspired staff, and a barely functioning zoological society. Within months, he started to turn the place around through sheer energy, personal charm, boyish enthusiasm, and a strong commitment to conservation and research. Warren and his wife Ghislaine became treasured icons in the community. These were some of the best days at the zoo.

Warren was not a herpetologist but loved and supported herpetology. He secured funding for three research initiatives for the zoo herp staff and outside colleagues: 1) herpetofaunal survey of the Sierra de los Cuchumatanes in northwest Guatemala (with Jonathan A. Campbell and Edmund D. Brodie, Jr.); 2) Bushmaster study at La Selva, Costa Rica, developed by Harry W. Greene, which involved travel to that lovely setting by the entire staff; 3) analysis of Panther Chameleon biology in Madagascar (with Gary W. Ferguson, Jean-Baptiste Ramanamanjato, and Achille Raseliminana). Staff development was important to Warren so he made sure that monies were available for our staff, even when our budget was tight, to attend national and international herpetological meetings and training programs.

His memory was prodigious. Within a few months after arriving at the zoo, he knew the names of not only the entire zoo staff, members of the Dallas Zoological Society, and fellow workers in the City of Dallas, but the names of their spouses and children as well. Since he had total recall of our conversations, I could never put anything over on him.

Warren did not tolerate complacency and pushed me in directions that were to me unimaginable. Before he came to Dallas, our department essentially operated as an isolated fiefdom and we made little effort to interact with others in the zoo, our zoo visitors, or the broader zoo community. During my first annual evaluation, Warren made clear that in the future I would be judged in broader terms; no longer would my isolated and misanthropic way of doing things be accepted. Naturally, I was devastated and after several weeks of soul-searching, I concluded that he was right and

made an effort to change my approach; I became a more-well-rounded and better zoo professional as Warren would accept nothing less. It is rare that a new boss pushes a long-term employee in this way and unless it is done properly, it can be traumatic and destructive for both sides. Warren did it properly.

Warren was a caring director and the following anecdote underscores this point. Ghislaine and Warren hosted a series of parties at their home for the entire zoo and zociety staff, which numbered about 300 persons. These were not catered events—all of the food was prepared beforehand and served to all of the attendees by the hosts.

Our weekly staff meetings were energetic, unpredictable, and filled with mirth. Since Warren's mind was so fertile, the ideas would flow in an unquenchable torrent from his lips and we had to struggle mightily to keep up with the pace. Subjects ranged from the lack of viable conservation programs in zoos, which fishes breathe air, parental care in salamanders, ophiophobia in primates, cleanliness in the public restrooms (Warren wanted to put Gary Larsen cartoons in the stalls to occupy the patron), pro football, embryo transfer into surrogate mothers, collection and cryo-preservation of gametes and do or should zoos need the "frozen zoo," responsibilities of the press, animal welfare issues, lack of opportunities for minorities in our profession, global warming before it was fashionable, failed management strategies, zoo scandals, and so on—no topic was considered to be too delicate or sacrosanct. Often, we left these meetings so highly charged that we adjourned to the local pub to finish our discussions into the wee hours.

When Warren and I left the zoo, we kept in touch regularly. One remarkable characteristic of our conversations was that he rarely dwelled on his life but always wanted to know how my family and I were doing. He loved to talk about his friends and colleagues and explore the intricacies and challenges of the zoo business.

Many months ago, he was diagnosed with lung cancer and during the past several months was undergoing radiation and other treatments at a local hospital. Even during the last days of his illness, he inquired about my family and my well-being and I had to press him to talk about his condition and how he was doing.

I am sad to say that Warren passed away on 5 August 2006. When his condition deteriorated, he wanted to go home, and so spent his last few days with Ghislaine and brother Bernie in that place. The day before, he slipped into a coma but Ghislaine said that he was peaceful at the end.

Warren was a wonderful boss . . . challenging but not demanding. His presence in my life stretched me both intellectually and professionally. I will miss his wise counsel and friendship—and his infectious laugh so precious.

ZOO VIEW

I enjoyed reading Kevin Murphy's article about the Buffalo Zoo because it brought back memories of my earlier association with Director R. Marlin Perkins at the Lincoln Park Zoo in Chicago during the 1950s. Perkins was assuredly the most well-known zoo personality in the United States with his television shows "Zooparade" and "Mutual of Omaha's Wild Kingdom." The American Zoo and Aquarium Association issues an annual award called "Marlin Perkins Award for Excellence" to a zoo worker chosen for significant contributions to the profession.

During the 1950s when my parents occasionally decided that my collection of reptiles at home had to go, mostly due to untimely escapes, my herpetological treasures always went to the Lincoln Park Zoo. With heavy heart, I periodically carried my charges to the reptile building although I was already planning my next ploy to bring more herps home when my parents settled down and became resigned to my unusual interest. During these purges, I met R. Marlin Perkins, Edward Maruska, Gene Hartz, Ray Pawley, and Ed Almandarz. They subsequently spent hours explaining the intricacies of the zoo business, encouraging me to give it a try as a career. Since it was clear that I was ill-equipped to do anything else, their wise counsel prevailed. Marlin Perkins was the only dissenter; he insisted that the zoo business would thrust me into a life of insolvency, chaos, and frustration. Accurately predicting two out of three is not bad!

Although I mentioned this experience earlier (Card and Murphy 2000. Lineages and histories of zoo herpetologists in the United States. Herpetol. Circ. No. 27:1–44), it bears repeating as it was a defining moment of my life: "While a high school student, JBM was introduced to Perkins by Gene Hartz. JBM timidly knocked on his office door, entered cautiously and spent an unforgettable thirty minutes with him. Perkins told JBM that getting into the zoo business was the greatest mistake of his life. His frustrations were exacerbated by indifferent politicians, zoo workers, and personal friends who could not understand his passion for animals. Further, zoo finances were always unstable and his bosses were jealous of his TV fame. Finally, Perkins advised the impressionable lad that if he were stupid enough to embark on a career in zoo herpetology, fate would deal a cruel and unrelenting blow to his entire life. Perhaps he was right?"

R. Marlin Perkins and chimp. Undated photograph provided by Kraig Adler.

Later, when I was at the Dallas Zoo, Perkins came to visit and charmed all of the herpetological staff with his stories about zoo herpetology in the early days. One of the most memorable was his description of the near-fatal Gaboon Viper bite in 1928 at the St. Louis Zoo. His assistant, Moody Lentz, was holding the smallish snake as Perkins was trying to remove an eyecap; he was envenomated with one fang. This was before the days where a monovalent antivenin was available for this species so American pitviper polyvalent, followed by cobra serum and an additional one to counteract Fer-de-lance and other *Bothrops* venoms were used—Perkins nearly died. He concluded his anecdote by saying, ". . . that the doctors threw everything but the kitchen sink at me and I still survived!"

Rick Hudson in the Fort Worth Zoo's conservation department has been the prime force in the impressive and successful captive breeding/reintroduction program for the critically endangered Jamaican Iguana and other *Cyclura* species. Rick has published three chapters on translocation, headstarting and the role of zoos relative to West Indian iguanas in the book *Iguanas: Biology and Conservation* (2004. Alberts et al. [eds.]. Univ. California Press, Berkeley).

A Jewel of a House

KEVIN J. MURPHY
Animal Curator, Buffalo Zoo
300 Parkside Avenue, Buffalo, New York USA, 14214
e-mail: kmurphy@buffalozoo.org

In 2005 the Buffalo Zoo renovated a little bit of history. The zoo closed down its Reptile House for seven months for some exciting improvements. Lead paint in the exhibit murals, threatening to become an animal health concern, was the impetus to start the project. The murals dated back to 1942 when the Reptile House was first opened. The Reptile House is part of the Main Building of the zoo which was a Works Project Administration (WPA) product, one of many building projects around the country. At the time the Reptile House was being built, R. Marlin Perkins, a renowned herpetologist, was curator at the Buffalo Zoo. Perkins took great pride in exhibiting reptiles in what at the time were considered very naturalistic exhibits. The murals depicted in the reptile exhibits helped boost the aesthetic and educational value of the individual exhibits and the reptile house in general.

In modern exhibits too, murals can add a great deal to the accurate exhibitry of the animal and facilitate attaining the goal of a truly natural looking exhibit. Visitors viewing a well done naturalistic exhibit can passively learn a great deal about an animal, just by observing the animal in its natural habitat.

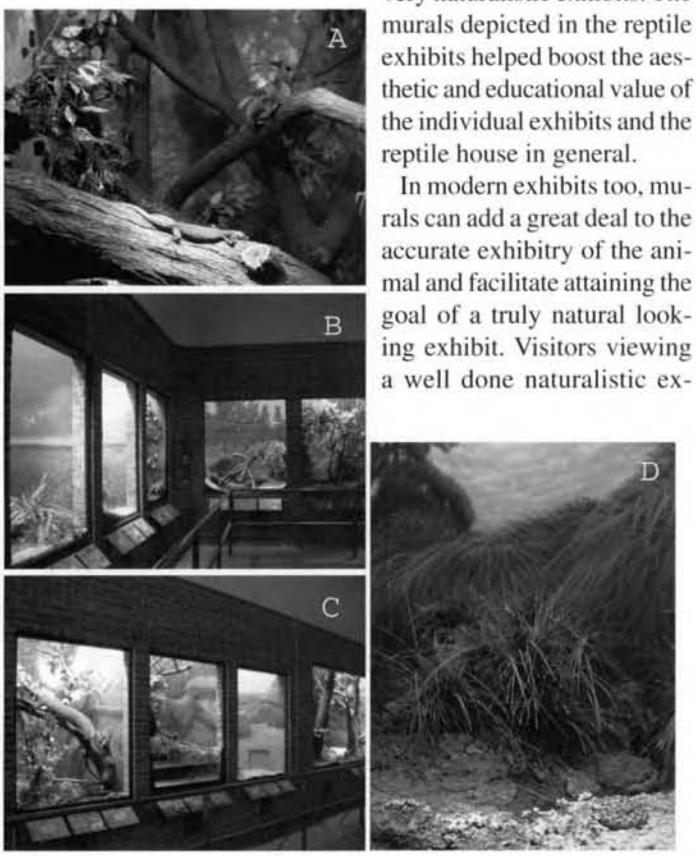

Fig. 1. A) Black Tree Monitor (*Varanus beccarii*) basking in its newly designed arboreal exhibit. Elevated, exterior nest box can be accessed by the lizards through the tree hole visible in mural. B) Exhibits showing graphics and a variety of habitats. Exhibit in center with pine tree houses Eastern Diamondback Rattlesnake (*Crotalus adamanteus*), Gopher Tortoise (*Gopherus polyphemus*), and Southern Fence Lizard (*Sceloporus undulatus undulatus*), one of several new mixed species exhibits in the house. C) Exhibits including Mata Mata Turtle (*Chelus fimbriatus*)/Emerald Tree Boa (*Corallus caninus*) display with underwater viewing. D) Mexican Lancehead Rattlesnake (*Crotalus polystictus*) exhibit created from photos of habitat near Atlacolmulco, Mexico.

Zoo staff had been trying to cope with the deteriorating murals for years. Lead abatement companies must be licensed and follow rigorous protocols in the removal process to prevent the release of super fine lead particles into the air. Due to the high costs of abatement, staff had been unable to appropriately remove any of the paint. Finally, a local labor union was contacted and an agreement was worked out with their abatement training school to use the Reptile House as a training facility.

Once the Perkins era murals were removed there was a tremendous amount of repair work done by zoo staff. Every wall of the 26 exhibits was patched, sanded, and primed. Each of the exhibits was originally built with hand-troweled concrete plaster walls that incorporated curved corners in the rear of the exhibits. These walls are very conducive to placing naturalistic props and the curved corners aid in mural continuity. In addition to the wall work, zoo staff spent numerous hours refurbishing the 1940s-vintage metal work that makes up the doors, doorframes, and shift doors assemblies. When Perkins designed the House he had the foresight to build a number of the enclosures with remotely operated shift cages as well as "peep" windows in all the keeper entry doors.

Once the prep work was done, photo references for each animal's habitat were painstakingly developed. Nationally renowned muralist David Rock used the photo references to create accurate, realistic murals. Each exhibit has a different habitat portrayed that seems to keep visitors engaged as they experience what the building has to offer. Once the initial murals were completed the project seemed to take on a life of its own. The zoo found the money to replace the majority of the badly etched glass fronts as well as for educational graphics throughout the building.

Exhibits were completed with three-dimensional props, misting systems, and new lighting schemes. Staff experimented with a number of new exhibitry techniques including an underwater view for a Mata Mata turtle exhibit.

In mid September 2005, the first exhibits were ready for their inhabitants. It was a very exciting time for staff. Special care had gone into re-building the exhibits and hiding the lights and misting systems. The animals in the exhibits now have more choice in terms of temperature and humidity gradients as well as how they can use the exhibit spatially. This was the first time since it opened that the Reptile House had been completely emptied and renovated. The house now looks fresh and new. There are a number of fascinating new species exhibited with special attention given to mixed species exhibits (Figs. 1A–D). As staff continues to strive for excellence at the Buffalo Zoo it seems likely that Marlin Perkins would be proud of this jewel that he started over 65 years ago. Zoo staff members certainly are.

Herpetological Review, 2006, 37(4), 402–403.

The International Iguana Foundation: Providing Critical Support to Endangered Iguanas

RICK HUDSON
Fort Worth Zoo, 1989 Colonial Parkway
Fort Worth, Texas 76110, USA
e-mail: rhudson@fortworthzoo.org

When a group of iguana biologists and conservation professionals gathered in Fort Worth, Texas, in August 2001, it signaled the beginning of a new era for iguana conservation. The group convened to address the critical need to provide a reliable source of funding for iguana conservation, particularly to support ongoing recovery programs for some of the critically endangered iguanas of the genus *Cyclura*. Shortly thereafter, the International Iguana Foundation (IIF) was formally established as a registered nonprofit organization and with it, the futures of a number of endangered iguanas grew more secure.

The IIF is a diverse group of conservation professionals, combining years of experience with multidisciplinary expertise. With a governing board comprised of research scientists, zoo administrators, professional fund-raisers, field ecologists, captive managers, private breeders, and veterinarians, the IIF brings a uniquely broad perspective to iguana conservation. Currently the IIF has 14 board positions with individuals representing zoos and aquariums, corporations, wildlife trusts, and foundations. Largely U.S. based, the majority of Board members represent zoos that have made long-standing commitments to *Cyclura* conservation, including Audubon, Columbus, Fort Worth, Gladys Porter, Houston, Indianapolis, San Diego, Sedgwick County, Shedd Aquarium, Toledo, and the Wildlife Conservation Society. Disney's Animal Kingdom is our sole corporate partner, and Durrell Wildlife Conservation Trust (formerly Jersey) is our lone foreign member. However the IIF is currently making a strong push to recruit more participation from both Europe and Australia. The single private sector representative is the California-based International Reptile Conservation Foundation (IRCF), a relatively new nonprofit that publishes the journal IGUANA and that has been instrumental in developing the IIF's web site: <www.iguanafoundation.org>. The President of the IIF is Dr. Allison Alberts, newly appointed Director of Conservation & Science for the Zoological Society of San Diego, and an accomplished iguana research biologist with a remarkable body of published work to her credit.

The IIF mission is to ensure the survival of iguanas and their habitat through conservation, awareness, and scientific programs. This translates to one simple overarching goal: zero iguana extinctions.

The IIF's primary purpose is to raise the financial resources essential to implementing iguana conservation programs. Working in tandem with the Iguana Specialist Group (ISG) of the World Conservation Union (IUCN), the IIF provides critical support to initiatives prioritized in the ISG's Conservation Action Plan and in the various Species Recovery Plans drafted under that group's auspices. In addition, IIF works to generate public awareness of the many threats facing iguanas.

Prior to the formation of the IIF, the conservation of Caribbean rock iguanas was largely handled by the ISG. Formed as the West Indian Iguana Specialist Group in 1996, the group expanded its mandate to include all iguana species in 2000. The ISG did an admirable job of prioritizing and facilitating iguana conservation work, primarily in the West Indies. The group achieved remarkable success in terms of fund-raising and grant writing, matching resources with project needs, providing logistical support and scientific oversight to recovery programs, developing headstarting facilities, conducting field research and predator control and a host of other activities.

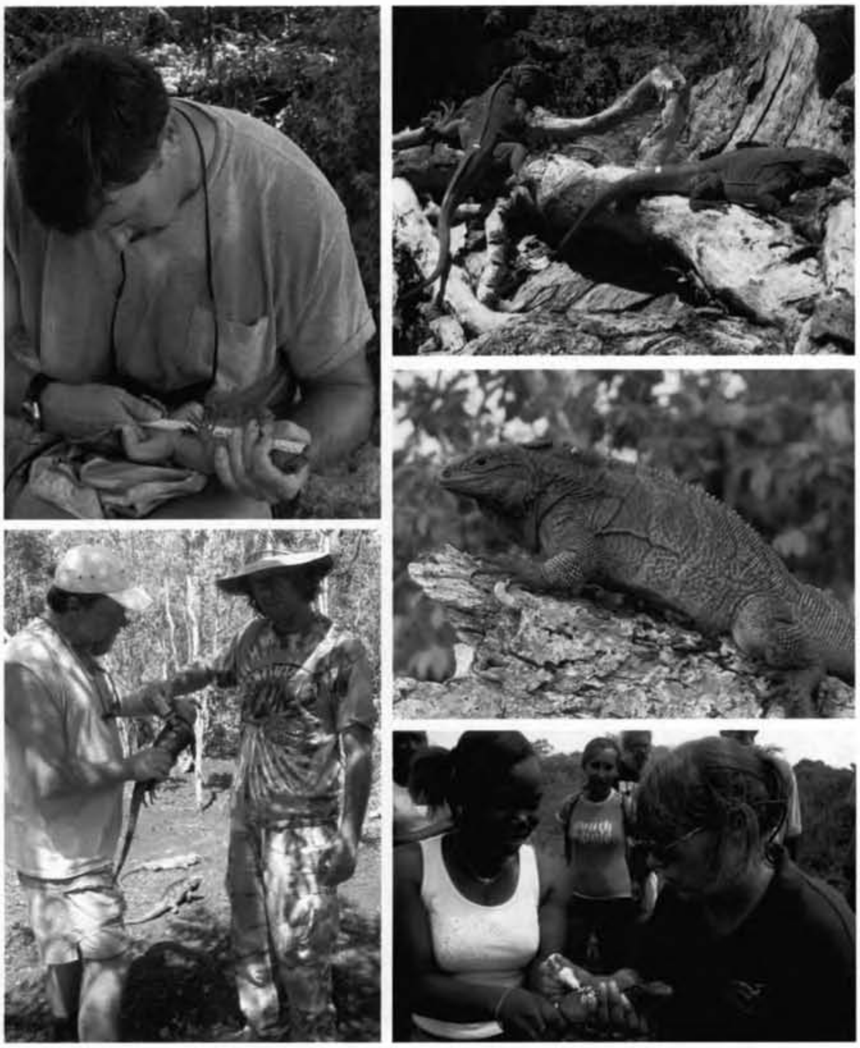
The strength of the ISG rests with their ability, through the international recognition that comes with IUCN affiliation, to forge working relationships with foreign governments, trusts and conservation NGOs (nongovernmental organizations). The ISG has developed a Species Recovery Plan (SRP) process. Since 2001, the group conducted workshops for the Grand Cayman Blue, Anegada Iguana, Ricord's Iguana, Turks and Caicos Iguana, Andros Iguana, and recently (and the first venture outside the Caribbean) the Fiji Crested Iguana. These SRP workshops are conducted in conjunction with the ISG annual meeting, where the group reviews the ever-changing list of priority species and projects. This list is made available to the IIF to use as they award funds and grants for projects.

Where the ISG is long on expertise, they are short on financial resources, which is where the IIF steps in. The close working relationship between these two groups is essential to ensure that the limited funds available for iguana conservation are used wisely and reflect the current prioritized needs. The strength of this process is that all decisions, both regarding funding (IIF) and species priorities (ISG) are made with consensus and under peer-review, which assures a broad and disciplined perspective.

Since its inception, the IIF has raised more than $484,000, primarily through direct board member annual contributions from supporting partners. The IIF also receives grants and public donations. Each supporting partner contributes from $2,500 to $10,000 annually; additionally, partners respond to requests for special project assistance or appeals for emergency needs such as those wrought by Hurricane Ivan in 2004 or the Blue Iguana extinction crisis of 2002.

The IIF applies for annual Disney Wildlife Conservation Fund (DWCF) grants that are earmarked for special large-project needs. Since 2002, the DWCF has been especially generous to the IIF, having awarded $68,750 for projects in Grand Cayman, Jamaica and the Turks and Caicos islands. The IIF has administered over $142,000 in grants from sources, including the Morris Animal Foundation (MAF), the SSC Sir Peter Scott Fund for Conservation Action, AZA's Conservation Endowment Fund, USFWS, and Conservation International. The largest of those, a $46,440 grant from MAF, funded medical evaluations on five *Cyclura* species, including pre-release health screening and establishing normal physiologic values on free-ranging animals.

The IIF is able to manage these conservation funds effectively because they have no overhead or paid employees. As one of the IIF's founding partners, the Fort Worth Zoo supports me to devote 40% of my salaried time to iguana conservation activities, including serving as the group's Executive Director. The zoo likewise supports the IIF's administrative office, one of two nonprofit rep-



From top left, clockwise: ▶ Glenn Gerber, PhD (San Diego Zoo CRES) collects data on a Stout Iguana, *Cyclura pinguis*, prior to being released in October 2004. ▶ The first group of 24 *C. pinguis* was released in October 2003, in two distinct habitat types on Anegada, BVI. In total, 101 iguanas have been repatriated from 2003 to 2006. ▶ A *C. pinguis* male, indicated by the red paint mark, rests on a dead tree following release on Anegada, October 2003. ▶ Kelly Bradley (Dallas Zoo), with help from a local Anegadan student, applies a white paint mark to a female iguana prior to release in 2005. Kelly successfully radio-tracked 72 iguanas on Anegada from 2003 to 2006 and obtained overall survivorship data of ~85%. ▶ Rick Hudson (Fort Worth Zoo) and Rick Van Veen (field coordinator for the Jamaican Iguana Recovery Team) apply a paint mark to a female *C. collei*, prior to release in the Hellshire Hills, February 2005. 67 *C. collei* have been repatriated since 1996.

tile conservation organizations (the Turtle Survival Alliance being the other) headquartered here, reflecting the zoo's strong tradition of commitment to herpetological conservation.

Conservation funds are allocated annually through a grants program. Since 2002, the IIF has awarded at total of $210,000 in four grant cycles to the following high priority projects: Blue Iguana Recovery Program, Grand Cayman; Jamaican Iguana Recovery Program; Anegada iguana research and conservation, British Virgin Islands; San Salvador Iguana translocation, Bahamas; St Lucia field research and conservation; Ricord's Iguana field research, Dominican Republic, Mona Iguana population monitoring and Fiji Crested Iguana field surveys.

The intent of the IIF is to address critical conservation needs, and three of the mainstays that fall into this category are the ongoing recovery programs for the Jamaican (*Cyclura collei*), Grand Cayman Blue (*C. lewisi*) and Anegada (*C. pinguis*) iguanas. All three are ranked Critically Endangered by the IUCN Red List and are considered conservation dependent; that is, the risk of extinction is too high to ignore the annual program needs. Intervention is necessary to offset the major threat, primarily high juvenile mortality associated with invasive feral predators. Not funding these programs is simply not an option. Therefore, the board recognizes that there will always be certain fixed costs associated with the grants program, however a solid proposal based on good science is still expected.

The IIF reached a major milestone in 2005: 100 individual iguanas of three species (Jamaica, Grand Cayman, and Anegada) returned to the wild with IIF funding since 2003. The October 2005 and 2006 releases of 24 and 29 Anegada iguanas respectively, surpasses that milestone, bringing to 224 the number of iguana repatriated to the wild with funding support from the IIF. In recent years the IIF has emerged as a major force for iguana conservation. And though the IIF has successfully raised a considerable amount of money, the group is constantly faced with worthy projects that are in serious need of financial support, but remain unfunded. Spiny-tailed iguanas of the *Ctenosaura melanosterna* complex fall into this category and will require considerable conservation funding in the coming years if they are to persist. Difficult choices have to be made. Such decisions are even more difficult with the realization that tried and tested conservation solutions exist for some of the highly endangered iguana species.

The expertise and techniques are available to help them; however, the pace of recovery is dictated by funding. For many species, rather than boldly forging ahead, the best that can be done is "holding the line" because of funding limitations. The IIF faces the challenge of reversing this situation, and to become better positioned financially to allow iguana conservation to move ahead at the pace that matches the need. For endangered iguanas worldwide, the IIF offers a fighting chance at survival.

The IIF is 501 c (3) nonprofit foundation registered in the State of Texas. Tax deductible (for U.S. taxpayers) contributions can be made with checks made payable to the IIF and sent to Rick Hudson, IIF, 1989 Colonial Parkway, Fort Worth, Texas 76110, USA, or on-line at <www.iguanafoundation.org> and click on contribute.

Amateurs, Professionals and Showmen: Taking Risks and Steve Irwin

TERRY D. SCHWANER
Department of Biology, North Georgia College & State University
Dahlonega, Georgia 30597, USA
e-mail: TDSchwaner@ngcsu.edu

Some of us study animals to answer fundamental questions about their ecology, evolution and natural history, while others learn just enough about an animal's behavior to be dangerous to themselves, and sometimes to others. In Australia, prior to my departure in 1989, people who engaged in scientific studies of dangerous animals, the ones who sought to publish scientific papers, were few and virtually confined to universities, museums, or Australia's Commonwealth Scientific and Industrial Research Organization (CSIRO). The professional field has grown since then, although the number of studies requiring "hands on" field work, particularly with highly venomous snakes, has not changed much. On the other hand, there was never a shortage of Australians who caught, kept, and often displayed dangerous animals.

The contrast between Australian scientific types and the lay public is perhaps exemplified by Banjo Patterson's poem, "Johnson's Antidote," that describes Johnson as a "free selector" (in this case a swagman, or an Aussie battler), always searching for a quick way to make a living, who witnessed a fight between a goanna and a venomous tiger snake. The goanna finally kills and eats the snake, surviving numerous bites ostensibly by nibbling the leaves of some plant. Johnson believes the plant harbors an antidote, and seeks the advice of a "scientific person" (actually a museum curator) for how to test it. The test shows the plant to be more deadly than the snake's venom, leaving the battler to battle on in search of fame and fortune.

As a "professional," finding populations of critters to study, especially if one was not born in Australia, required developing close relationships with "amateurs"—the risk-takers who handled those critters. They were the blokes (and Sheila's) who had read the popular accounts, traded husbandry notes, developed intense fascinations with particular species, applied what they knew to justify catching and handling them, and dreamed of one day finding their own "antidote," or running their own reptile park. And some did.

Joe Bredl, then owner of Bredl's Reptile Park near the riverland of South Australia, was a short, wiry man with a clipped white beard, a wonderful smile, and crisp Hungarian accent. Joe was quick to size me up as the new Curator of Reptiles at the South Australian Museum—and alas, a Yank! "Joe," I said, "where can we find some snakes?" "Oh, well it's too hot and dry mate," said Joe. The next day it rained—poured, rather—for several hours, and we caught lots of frogs, but no snakes. So I went back to Joe's park. "Joe," I asked, " where are the snakes hiding?" "Too, wet, mate," was Joe's reply. The front passed through and the humidity dropped, along with the temperature, so I asked once more, "Joe, any idea where we can find those snakes now?" "Too cold, mate, too cold." And that was my introduction to one of the most famous of the living "amateurs." I last heard Joe was bitten on the chest by an Inland Taipan or fierce snake, the world's most venomous terrestrial snake, while on a collecting trip. He nearly died. But being one of the few people to ever survive such an ordeal, Joe lavished in the publicity—he was now the stuff of legends, taking his place beside many other risk-takers.

"How many times have you been bitten?" the amateurs ask, when I tell them I've handled some ten thousand tiger snakes over the last 20 years. "None," I reply, "at least not envenomed." Their faces betray their skepticism and disbelief—one even blurts out, "Well, how can you call yourself a herpetologist, if you've never been bitten?" "Just lucky, I guess," shying away from the questions and not attempting to justify my apparent lack of experience. No credential—a childhood of catching snakes in the swamps behind my house in Louisiana, Bachelors, Masters, and Ph.D. degrees in herpetology, and postdoctoral experience in the biochemistry of snakes—nothing would impress them. Some know the risks of handling these highly venomous reptiles, but most, I think, only really understand (or learn to appreciate) the danger after they or a friend are bitten.

At a "show and tell" session, during a meeting of the Junior Herpetology Club of South Australia, a ten year old boy sat quietly with a knotted bag on his lap. When called on, he opened the bag, reached in, and took out a live, three-foot long taipan (the world's second most venomous terrestrial snake, and sometimes ranked as the worlds most dangerous). No one crowded around the young boy—all were too shocked to move. The snake seemed docile enough. "How long have you had that snake?" I asked, as calmly as I could. "Since it was a baby," he said. "I feed it mice by hand." Brian Miller, among the keenest of amateurs, and a close friend, grimaced at the comment. Just a few weeks before he'd told me about an incident in the cane fields of Queensland. "I saw this tail sticking out from between two railroad sleepers and I grabbed it," he said. "I thought it was a large whipsnake, but it was a taipan about four or five feet long. It doubled back, shot over my left shoulder and was gone in a second or so. I was so fortunate, as it could have bitten me thrice in the same amount of time." Brian congratulated the boy on the interesting snake he exhibited, and quietly asked that he put it back in the bag. Afterwards, we talked to him for over an hour about the dangers of handling such an unpredictable reptile. But the snake, apparently, was acquired legally, and after that night the boy never returned to the meetings.

Steve Irwin's first film on snakes was "The Ten Deadliest." Dr. Richard (Rick) Shine, of The University of Sydney, arguably one of the world's most scholarly herpetologists and an authority on Australian snakes, with over 500 refereed papers on amphibians and reptiles, reviewed the story line and videotape for Partridge Films. I also reviewed the materials. Rick and I agreed that Steve's handling abilities were cautious enough, but his dialog was meant for amateurs and lay people—handling snakes as gingerly as he did, examining them by holding their tails, and generally making a fuss over them, cooing about how mild their tempers were when "handled properly," were just a bit over the top. We scientific types take some twenty measurements, count numerous scales, examine for gender, reproductive condition and gut contents, draw blood

and venom samples, and mark, weigh, and photograph each individual. Using Steve's ideas, we would have given up the studies, or worked well into old age, to get enough data to finish our projects. But the part of Steve's film we found most objectionable, was the sight of him lying on the ground near a rat burrow, allowing a very large female inland taipan to approach and "lick" him on the cheek with her tongue flicks. That reminded me of the young boy with the taipan.

In spite of our objections, Steve's film was an instant success—particularly in the United States. Years later, a fellow herpetologist and keen field researcher told me that while trying to make a film on Eastern Diamond-backed Rattlesnakes in Georgia, he was notified of a recent snakebite victim, a young boy, just admitted to the local hospital. After the crisis was over, and the boy was interviewed, he was asked, "Why did you try to pick up that snake?" "I was just trying to be like the Crocodile Hunter," he replied.

Although my fascination with snakes has caused me to take many risks—most involved transport between islands in a rubber boat—I treated each snake as a research subject, with caution and a protocol for safety, as if each capture and handling was the first time. Over the years, I sensed that Steve Irwin, in spite of my reservations, perhaps subconsciously, did that, too. He most likely felt the same adrenalin rush and the same sense of accomplishment in collecting and displaying animals to the camera that I got from recording the data that, I hoped, would make my publications read and admired by my peers and the public. And, for a time, I eagerly accepted invitations of film crews from the ABC, the Cousteau Society, local and national television, and freelance cameramen working for the likes of David Attenborough, to make videos and television documentaries on tiger snakes. I even teamed up with Mark O'Shea on one of his 'big adventures,' and enjoyed it immensely. But all these were diversions from my real goal—to publish a book on the biology of these snakes—and that quest continues, today.

While in Australia in 2001, I also learned that Steve, the showman, was also Steve the conservationist, spending some of his earnings on the preservation of land for wildlife. This new perspective, related to me by an old friend at the South Australian Museum, changed my attitude toward Steve. Like most of his fans and detractors, I never knew him, personally. But, showmanship aside, conservation and land preservation for wildlife habitat, particularly in Australia, is admirable, no matter what the means are for doing it. My perspective changed. I began thinking more about the joy Steve displayed and how his work transferred wonderfully to his audiences. Wildlife expert, risk-taker, buffoon, comic, advocate, family man—he was all these things and more, and he projected his joy and enthusiasm for life into millions of homes.

I came to the conclusion there is a kinship among those of us who take risks with dangerous wildlife. Steve Irwin's death causes me to wonder how I survived all my years handling venomous snakes and to count my blessings. It also points, perhaps selfishly, toward a renewed sense of urgency to finish and publish my work, if for no one other than my wife, children, and grandchildren. When a person we all recognize dies, we may give pause to our daily chores and ask—what good have we actually contributed to humanity? Steve's impact will endure in his films. They will be seen by his wife and children, and remembered by all for a very long time.

Comments on Maximum Length in the Moila Snake (*Malpolon moilensis*) and Length Dimorphism in the Montpellier Snake (*M. monspessulanus*)

CORNELIUS C. DE HAAN
Loiras, 8 Route de St-Alban, Le Bosc 34700, France
e-mail: Haanpsam@aol.com

In the very interesting life history of the Moila Snake, *Malpolon moilensis* (Colubridae: Psammophiinae), as described by Gasperetti (1988), I was struck by the claim that Kramer and Schnurrenberger (1963) had recorded two female *M. moilensis* from Libya, of 1897 mm and 1899 mm total length. Kramer and Schnurrenberger (1963: 511–513) actually examined 19 specimens from Libya. Of these they indicated the length of only the longest one, a female of 910 mm (including tail 165 mm).

Gasperetti (1988: 253–257, 371 + appendix II) measured at least 47, and possibly as many as 144, Arabian *M. moilensis*, of which the longest was a female of 1213 mm (including tail 207 mm). Although he also mentioned a "non-measured"[*sic*], badly decomposed Arabian specimen "of over 1500 mm" (probably also in Gasperetti 1973), he seems to have excluded the possibility of the existence of Arabian specimens reaching 1900 mm, the size he ascribed to the Libyan specimens supposedly reported by Kramer and Schnurrenberger (1963). Despite his reservation regarding such large specimens, it appears that he mistook the collection numbers SK 1897 and SK 1898, listed by Kramer and Schnurrenberger (1963), for snake lengths in millimeters. A tiny additional error, possibly typographical, yielded the top record of 1899 mm. Apart from this, the distribution of *Malpolon moilensis*, correctly given by Kramer and Schnurrenberger (*op. cit.*) as extending from Mauritania and Morocco to Iran, was given by Gasperetti (1988), in his text and two maps, as extending only from Algeria to Iran. These errors were not present in Gasperetti's (1973) earlier treatment of *M. moilensis*, in which no Kramer and Schnurrenberger (*op. cit.*) specimens are mentioned either.

Unfortunately, Gasperetti's (1988) erroneous size record based on the SK-numbers has been repeated in the literature. In a study on biological diversity in Jordan, Disi (2002) stated that, according to Kramer and Schnurrenberger (1958[*sic*]), the two longest measured *Malpolon moilensis* are females from Libya of "189,7 cm and 189,9 cm total length." In another work (Disi et al. 2001), it is stated that there is a 190 cm maximum length for *M. moilensis* from Libya, with a list of thirteen "pertinent references." Among these Gasperetti (1988) is present but Kramer and Schnurrenberger (1963, or any other year) is not.

More erroneous statements on *Malpolon* sp. would have been avoided if Disi et al. (2001) had correctly interpreted the results of Kramer and Schnurrenberger's (1963) research; in particular, those results, subsequently corroborated by De Haan (1999, 2003), demonstrating that *M. monspessulanus* males grow much larger than females of the same age (maximum total length 230 cm vs. 140 cm), despite a lack of sexual dimorphism in tail length.

I hope that this letter will put an end to the repetition of errone-

ous lengths for the two *Malpolon* species, and will do justice to the excellent work on Libyan snakes by Kramer and Schnurrenberger (1963).

Stability Restored to the Name *Phymaturus palluma*: A Response to Cei and Scolaro (2006)

RICHARD ETHERIDGE
and
JAY M. SAVAGE
Department of Biology
San Diego State University
San Diego, California 92182-4614, USA
e-mail (RE): rether@sunstroke.sdsu.edu
e-mail (JMS): savy1@cox.net

We initially prepared this article at the request of the editor in response to a manuscript submitted to this journal by J. M. Cei and A. J. Scolaro regarding the recent action of the International Commission on Zoological Nomenclature (ICZN), designating a type species for the iguanian lizard genus *Phymaturus*, and a neotype for the species *Phymaturus palluma* (ICZN 2005). However, the manuscript of Cei and Scolaro was subsequently withdrawn, and an expanded version recently appeared in the journal *Zootaxa* (Cei and Scolaro 2006). The following is brief history of this case, taken from our application to the ICZN (Etheridge and Savage 2003).

The genus *Phymaturus* (Gravenhorst 1837) has been used for over 150 years for a group of lizard species that occur in the cordilleras of central Chile and Argentina, and on several volcanic mesestas of Patagonian Argentina. Cei and Lescure (1985) determined that the type species of *Phymaturus*, *Lacerta palluma* Molina 1782, was misidentified by Gravenhorst (1837), and that Molina's description was actually based on a specimen of the teiid species *Callopistes maculatus*. Consequently, Cei and Lescure (1985) proposed replacing *Phymaturus palluma* with *Callopistes palluma*. Subsequently, Lescure and Cei (1991) proposed revalidation of the next available generic name, *Centrura* Bell (1843), for all species referred to *Phymaturus*, and replacement of the name *Centrura flagellifer* with *Phymaturus flagellifer*. Etheridge and Savage (2003) then applied to the ICZN, in the interest of nomenclatorial stability and universality, to use its plenary powers for the purpose of designating the holotype of *Centrura flagellifer* Bell 1843, as the neotype of *Lacerta palluma* 1782, and to place the names *Lacerta palluma* Molina 1782 and *Phymaturus* Gravenhorst 1837 on the Official List of Names in Zoology. Two years later our application was approved (ICZN 2005, Case 3225).

Cei and Scolaro (2006) argue that the decision of the ICZN was a mistake. They repeat the assertion of Cei and Lescure (1985) that the specimen upon which Molina (1782) based his description of *Lacerta palluma* was actually a specimen of the teiid lizard now known as *Callopistes maculatus*, and attribute the initial error of identification to Daudin (1802). The conclusions of Cei and Lescure (1985) were based on a detailed comparison of *Lacerta palluma*, as described by Molina (1782), with the characteristics described by Gravenhorst (1837) for *Phymaturus palluma*, and with those of *Callopistes maculatus*. We have made the same comparisons, and find their conclusion that Molina's specimen was probably a *Callopistes* to be convincing. Although we have never disputed this assertion, we believe the initial error was likely that of Gmelin (1788) and Meyer (1795) rather than Daudin (1802). Gmelin (1788), citing Molina (1782) listed *Lacerta pelluma* [sic] between *Lacerta cordylus* (Linnaeus 1758) (now *Cordylus cordylus*: Cordylidae) and *Lacerta stellio* (Linnaeus 1758) (now *Laudakia stellio*: Agamidae), both species having a spiny tail. Meyer (1795), citing Gmelin (1788) then placed *Lacerta pealuma* [sic] in the genus *Cordylus*, apparently because Linnaeus (1758), in his description of *Lacerta cordylus* used the term "*cauda verticillata*" (tail whorled), employed also by Molina (1782) in his description of *Lacerta palluma*. Because *Cordylus cordylus* is a lizard with a spinose tail, Meyer (1795) apparently incorrectly assumed the tail of Molina's species was also spinose. Subsequent authors appear to have perpetuated this error. Latreille (1801) and Daudin (1802) used the genus *Stellio* for *Lacerta palluma*, Cuvier (1829) used *Oplurus*, and Kaup (1826) used *Uracentron*, all genera characterized by a tail with whorls of spinose scales. It is not surprising, therefore, that when Gravenhorst (1837) was presented with a spiny-tailed lizard from Chile, he assumed it was Molina's *Lacerta palluma*. Thereafter, the name *Phymaturus palluma* was used consistently and universally until 1985. The revalidation of the next available name, *Centrura flagellifer* (Bell 1843) by Cei and Lescure (1985), and their subsequent proposal to again change the name to *Phymaturus flagellifer* (Lescure and Cei 1991) ushered in two decades of instability during which *Centrura flagellifer*, *Phymaturus flagellifer*, and *Phymaturus palluma* were used for the same species. Our sole objective in submitting this case to the ICZN (Etheridge and Savage 2003) was to bring an end to this instability once and for all.

Alterations in Frog Assemblages After Hurricane Iris in Belize

TANYA J. HAWLEY

Department of Biology, University of Miami
P. O. Box 249118, Coral Gables, Florida, 33124, USA
e-mail: thawley@bio.miami.edu

Hurricanes alter forest vegetation structure causing extensive defoliation, limb breakage, and uprooting of trees (Tanner et al. 1991). This reduction in canopy cover results in decreased humidity and increased light penetration and wind speeds, paralleling changes that occur locally in tree fall gaps (Hubbell and Foster 1986). Loss of canopy cover due to Hurricane Hugo in Puerto Rico resulted in increased temperatures near the forest floor and abundant growth of understory vegetation (Stewart 1995). Natural disturbances may stimulate vertebrates to respond in physiological, behavioral, or ecological manners (Karr and Freemark 1985). Habitat alterations can influence vertebrate species composition and population density (e.g., Reagan 1991; Woolbright 1991) through changes in predator-prey dynamics, food supply, and availability of retreat sites (Schoener et al. 2001). Such alterations can occur immediately and be long lasting (Waide 1991).

Few studies have quantified the response of animals to hurricanes. The densities of nectivorous and frugivorous birds (Askins and Ewert 1991; Lynch 1991; Waide 1991) and invertebrates such as phasmids and snails (Willig and Camilo 1991) were significantly reduced after hurricanes. The vertical microhabitat of *Anolis* species changed after Hurricane Hugo forcing three species to use habitat near ground level (Reagan 1991). The most detailed analyses of hurricane effects on an amphibian are those of Woolbright (1991, 1996) and Stewart (1995) on *Eleutherodactylus coqui* in Puerto Rico. One year following Hurricane Hugo, *Eleutherodactylus coqui* showed a fourfold increase in adult population size, likely because of an increase in retreat sites and decrease in predatory invertebrates (Woolbright 1991). A recent study (Vilella and Fogarty 2005) also reported an increase in the abundance of *E. coqui* but decreases in the abundance of two other eleutherodactylids after Hurricane Georges. Amphibians are sensitive to microhabitat changes and are considered indicators of ecosystem perturbation due to their unique life histories and physiologies (Blaustein and Wake 1995; Phillips 1990). Furthermore, pond-breeding species are influenced by vegetative changes occurring within ponds and surrounding terrestrial habitats (Semlitsch 2000). Therefore, pond-breeding frogs should be excellent model organisms to study the impact of hurricane disturbance.

Hurricane Iris (Class IV) struck southern Belize in October 2001. A 20-month study conducted prior to the hurricane (February 2000 to September 2001) examined the breeding phenology and habitat associations of frogs in several pond-breeding sites in the Bladen Natural Reserve (BNR; Hawley 2002). The availability of these pre-hurricane data presented a rare opportunity to examine the

effects of a hurricane on diverse anuran assemblages in multiple sites of different habitat types. Furthermore, predictions could be made regarding the response of anurans to changes in vegetation caused by Hurricane Iris. Hawley (2002) identified several species, including *Bufo valliceps*, *Hyla microcephala*, *Smilisca baudinii*, *Leptodactylus melanonotus*, *Rana berlandieri*, and *Rana vaillanti*, as common, habitat generalists, i.e., occurring within pine-savanna and forest habitats. In contrast, *Agalychnis callidryas*, *Hyla loquax*, *Hyla ebraccata*, *Gastrophryne elegans*, and *Rhinophrynus dorsalis* were specialists of forest habitat and *Hyla picta*, *Scinax staufferi*, and *Leptodactylus fragilis* were specialists of pine-savanna habitat. I expected habitat specialists, which are limited by particular physical and biological characteristics that occur within their range of habitat (Hutchinson 1957), to undergo more changes in their abundance and distributions than habitat generalists. For example, some hylids (e.g., *A. callidryas*) are confined to the forest because the canopy provides protection from high temperatures and low relative humidity that may be physiologically stressful. In contrast, other hylids (e.g., *H. picta* and *S. staufferi*) occur in areas with tall understory growth (Lee 1996), which serves as habitat for perching during the breeding season. If Hurricane Iris altered the quality of habitat for these species, I expected to observe changes in assemblage composition and their abundance at the study sites.

In this study, I compare frog species richness, composition, and abundance and canopy cover pre- and post-hurricane at six breeding sites. These pre-hurricane surveys in combination with post-hurricane surveys allow for changes in frog assemblages and vegetation structure to be assessed.

Methods

Study Sites.—I selected six study sites (each approximately 100 × 30 m) in the southeast portion of the BNR (16°33.124'N, 88°42.974'W) in the Toledo District of southern Belize in May 2000 (Hawley 2002; Fig. 1). Sites were selected based on their potential to serve as regular frog breeding ponds. Sites were located in primary tropical evergreen broadleaf lowland forest (F1–F4), short-grass savanna (S1), and transitional habitat (T1) (Meerman and Sabido 2001). F1 and F2 were located on a little-used, unpaved road between the Southern Highway and Bladen River and four sites (F3, F4, T1, and S1) were located off the road. Sites were a minimum of 100 m apart, with the most distant sites separated by 1.5 km (F1 and S1). I obtained daily precipitation and maximum and minimum temperatures for the years 2000–2002 from the Belize Foundation for Research and Environmental Education (BFREE), located ca. 750 m NE of site F1. The monthly maximum temperature was 32.28 ± 1.98°C (mean ± SD) and minimum temperature was 21.22 ± 2.83°C (mean ± SD) from 2000–2002 at BFREE. BNR is characterized by a distinct wet (May–October) and dry (November–April) seasonal cycle. Total annual precipitation was 2562 ± 66 mm (mean ± SD) from 2000 to 2002.

Anuran Surveys.—I conducted a minimum of six nocturnal audio surveys (Zimmerman 1994) in each site during June to August in 2000 and 2002 (Table 1). Survey effort was lower in 2001 with only two surveys conducted at some sites during the same time period. Surveys were conducted between 2000 h and 2400 h, corresponding to the time period of greatest frog vocalization, and survey duration was a minimum of ten minutes. I estimated the number of calling males of each species and noted it as an index of 1 to 4, standard in the Maya Forest Amphibian Monitoring Project (MayaMon) (Meyer 1999). A score of 1 indicates that 1–5 individuals were calling; 2 indicates 6–20 individuals; 3 indicates 21–50 individuals; and 4 indicates over 50 individuals. Surveys were conducted during a period of 2–5 days each month and a subset of sites were visited each night. The order in which sites were visited was varied on consecutive nights each month so that each was visited during different time periods.

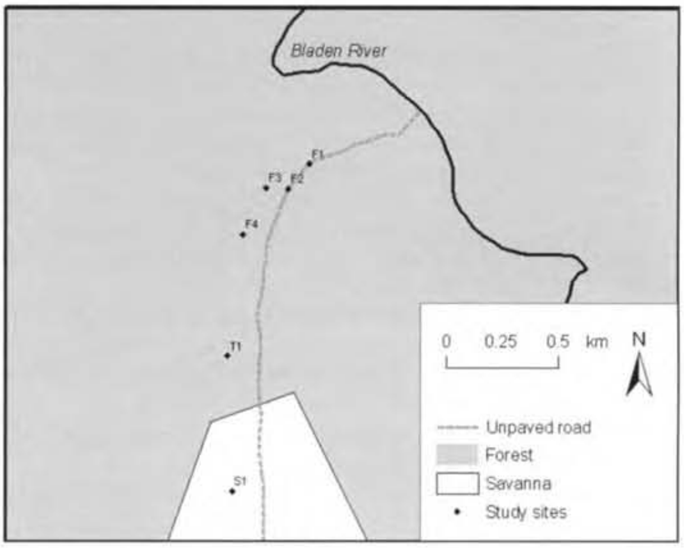

FIG. 1. Map of study sites in southern Belize. Detail of the Bladen Nature Reserve ecosystems was adapted from the Belize Ecosystems Map (Meerman and Sabido 2001).

Vegetation Structure.—I estimated percent canopy cover pre- (June–September 2001) and post- (June–August 2002) hurricane at each study site except T1. One plot (20 × 10 m) was established at the center of the pool in each site and divided into quadrats at 2 m intervals. Canopy cover was estimated using a sight tube divided into four equal parts with a string. At each 2 × 2 m quadrat intersection, I viewed through the tube upward and estimated the percent of canopy cover. A value of 0 to 3 was given, corresponding to 0–25, 26–50, 51–75, and >75% canopy cover.

Data Analysis.—I computed the total species richness in each site by pooling vocalization surveys from June to August each year. To represent the abundance of each species I used the highest value the calling index reached each year. Therefore, this value is an estimate of the largest size attained by the male breeding population of each species during the survey dates each year (Scott and Woodward 1994). I plotted species accumulation curves in each site during each year to examine how species richness changed with survey effort. When gamma diversity is low and species accumulation curves reach an asymptote, the curves are a satisfactory way to standardize effort among sites (Willott 2001). The curves reached asymptotes in two to six surveys; therefore, effort above six surveys did not reveal new species in any study site. If a minimum of six surveys is used to standardize effort among sites and years, then effort during 2001 was too low to offer a reliable comparison. However, years 2000 and 2002 can be compared to

examine how species richness, composition, and abundance varied pre- and post-hurricane. Throughout the remainder of the paper pre-hurricane will represent year 2000 and post-hurricane will represent year 2002 unless mentioned otherwise. I tested for a difference in species richness among sites pre- and post-hurricane using a Wilcoxon signed-ranks test for related samples, with sites as replicates. Then I tested for a difference in the number of sites each species occurred in pre- and post-hurricane with a Wilcoxon signed-ranks test for related samples, using species as replicates. Because of the possibility of a lack of independence among sites F1, F2, and F3 due to small inter-site distances, F2 was removed from statistical analyses.

Summary statistics were calculated for canopy cover in each site. I used a paired samples t-test to determine whether canopy cover differed pre- versus post-hurricane in each site.

Results

Frog Assemblages—Fourteen frog species of six families were observed during the study period (Table 1). Species richness increased at every site post-hurricane in comparison to pre-hurricane (Wilcoxon, $Z = -2.070$, $P = 0.038$). This trend remains even if additional survey effort is considered by pooling years 2000 and 2001 (Table 1). Furthermore, seven of 12 species were encountered in more sites post-hurricane; however, this difference was not significant (Wilcoxon, $Z = -1.552$, $P = 0.121$; Fig. 2). Of the seven species that increased in occurrence, four (*Hyla picta, Scinax staufferi, Smilisca baudinii,* and *Rana berlandieri*) were found in an additional two or three sites. In contrast, *Agalychnis callidryas* and *Leptodactylus melanonotus* were each encountered in one fewer site post-hurricane. The remaining species showed little (± 1 site) or no change in the number of sites they were detected in between time periods (Fig. 2).

The data suggest that the hurricane had neither an overall positive nor negative effect on the abundance of species (Table 1). In addition, no single species showed a consistent large increase or

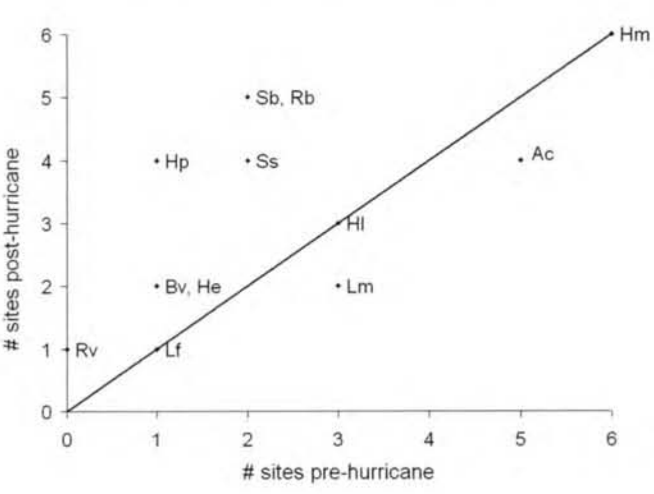

Fig. 2. The number of sites each species was detected in pre- and post-hurricane. Species abbreviations are the first letters of the genus and species names; see Table 1 for full names. The diagonal line represents no change in number of sites a species was detected in before versus after the hurricane.

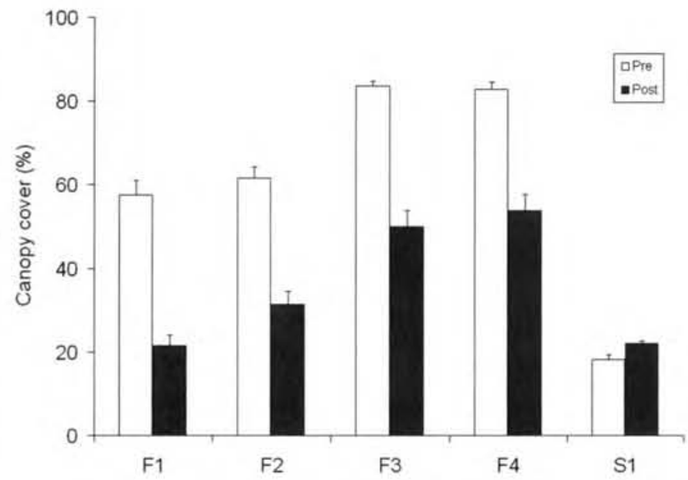

Fig. 3. Canopy cover (mean ± SE) pre- and post-hurricane at five study sites; each comparison between years was significant ($P < 0.05$) with paired samples t-tests.

decrease in abundance across multiple sites. However, fewer vocalizing *Agalychnis callidryas* were detected post-hurricane in several forest sites (Table 1). *Scinax staufferi* and *Hyla picta* were detected vocalizing post-hurricane in forest sites for the first time during the study period. In addition, the first observations of vocalizing *Smilisca baudinii* and *Rana berlandieri* at several sites occurred post-hurricane.

Vegetation Structure.—Canopy cover significantly decreased by approximately 30% (T-tests, $P < 0.001$) at all forest sites post-hurricane (Fig. 3). In contrast, there was a significant, albeit small, increase in canopy cover in the savanna site (S1) between time periods.

Discussion

The alteration of vegetation structure resulting from Hurricane Iris was typical of that found after other hurricanes of similar magnitude. Winds in excess of 224 km/h (Meerman 2001) caused uprooting of trees, limb breakage, and loss of canopy cover in the forest. Pine forest and savanna habitats are thought to have been the least affected by the hurricane (Meerman 2001). The results of this study support this idea, showing little change in canopy cover in the savanna site. However, alteration in the lowland forest structure resulted in a significant accumulation of debris on the forest floor (pers. obs.) and large openings in the canopy. These structural changes prompted the rapid growth of understory vegetation in several sites. Greater canopy openness has been positively correlated with increased light penetration, increased temperatures, and decreased ambient humidity on the forest floor (Hubbell and Foster 1986). Therefore, canopy cover can be viewed as a surrogate for these abiotic variables, which have a large influence on frog activity and distributions (Duellman and Trueb 1986; Pearman 1997). I propose that alterations in vegetation structure occasioned by Hurricane Iris caused some of the changes observed in frog occurrence and abundance during the study period. However, these structural changes were not so drastic as to cause significant population variation or the loss of anuran species in the study area during the study period.

TABLE 1. Species richness and abundance detected during vocalization surveys at each site from June to August in 2000 (00) and 2001 (01; Pre-hurricane) and 2002 (02; Post-hurricane). Numbers represent the maximum calling index reported in surveys during the time period at each site (1 = 1–5, 2 = 6–20, 3 = 21–50, and 4 = 50+ vocalizing individuals) and N = number of surveys during June to August each year at each site.

The most prominent changes in the frog assemblages after Hurricane Iris were increases in species richness and consequent changes in frog composition within those sites. However, no consistent trends across all species or all sites were found; frogs responded to the structural changes caused by the hurricane in species-specific manners. The increase in frog species richness at several sites was in part caused by an increase in the occurrence of *Scinax staufferi* and *Hyla picta* in forest sites after the hurricane. It is unlikely that these observations were an artifact of my sampling regime because they also were not observed in forest sites during surveys from June to August 2001. In contrast, post-hurricane, *S. staufferi* and *H. picta* were encountered in forest sites on several survey occasions. Both species were characterized as savanna habitat specialists within the study area prior to the hurricane by Hawley (2002). Typically, both breed in temporary pools in open areas, perching on emergent grasses and shrubs (Campbell 1998; Lee 1996). Post-hurricane, sites in the forest more closely resembled the vegetation structure of the savanna, with large openings in the canopy and greater understory vegetation growth. These structural changes may be responsible for the increased occurrence and abundance of *S. staufferi* and *H. picta* in forest sites post-hurricane. Increased understory vegetation cover in and around breeding ponds would provide additional perching sites for *S. staufferi* and *H. picta*.

Contrary to my expectations, most specialists of forest habitat did not undergo large changes in occurrence or abundance. *Agalychnis callidryas* showed small declines in abundance in several sites during the study period. *A. callidryas* is a canopy-dwelling species and is not found in sites without trees (Lee 1996); therefore, the reduction in its abundance in this study may be directly related to the loss of canopy cover in forest sites. Furthermore, increased temperatures and decreased relative humidity as a result of reduced canopy cover may cause physiological stress for *A. callidryas*, resulting in individuals moving to locations with more appropriate microhabitat conditions.

As expected, most species characterized as habitat generalists did not undergo large changes in occurrence or abundance. However, *Smilisca baudinii* and *Rana berlandieri* were detected in three additional sites post-hurricane. Unlike *S. staufferi* and *H. picta*, these observations do not suggest actual changes in the occurrence or abundance of these species because they were observed with regularity in many of the sites in surveys during months outside of the study period examined here (Hawley 2002). In addition, *S. baudinii* breeds explosively after heavy rains and therefore its presence at a site can be extremely variable. Three other species (*Gastrophryne elegans*, *Rhinophrynus dorsalis*, and *Bufo valliceps*) can be considered explosive breeders and consequently variation in the detection of these species among years can be attributed to this habit.

Although abiotic changes related to the hurricane were not directly measured in this study, the reduction of canopy cover suggests that changes in abiotic variables did occur as a result of the hurricane. Since it is well-known that anurans are sensitive to aspects of their physical environment (Duellman and Trueb 1986), it can be inferred that abiotic changes are at least partly responsible for the alterations in the composition of frog assemblages and the abundance of certain species observed here. Natural disturbance plays a large role in structuring temporal and spatial variation in communities (Sousa 1984). Some species disperse from habitats that are no longer suitable, while others specialize in colonizing newly disturbed habitats. Some of the patterns observed here are similar to those found in responses of birds to hurricane

disturbance. Waide (1991) reported that bird species that used a variety of habitats were pre-adapted to the environment of the post-hurricane forest in Puerto Rico. Moreover, an edge species, *Tiaris bicolor* (Black-faced Grassquit), colonized gaps in the forest post-hurricane (Waide 1991). Although frogs disperse on a much smaller scale than birds, movements of 500–700 m are within reason for frogs of a size similar to *Hyla picta* and *Scinax staufferi* (e.g., *Hyla regilla;* Reimchen 1991). The locations of the study sites along a natural gradient in canopy cover from savanna to forest may have facilitated the observation of small-scale changes in the local distribution of these species. These data suggest that natural disturbance events such as hurricanes may encourage species to temporarily occupy areas outside their usual habitat. Similar changes in the composition of frog assemblages may not have occurred in forested ponds more distant from the savanna-forest edge.

The findings here differ greatly from the large increase in abundance of *Eleutherodactylus coqui* observed one-year following Hurricane Hugo in Puerto Rico. However, *E. coqui* has direct development and inhabits leaf litter, making its life history much different from the species in this study. Overall, the results shown here demonstrate the resistance of pond-breeding frog assemblages to major changes in species composition and abundance as a result of hurricane disturbance. Habitat generalists and forest specialists underwent few changes in occurrence and abundance in the study sites. In contrast, two savanna specialists were encountered in forest sites subsequent to the hurricane. When examined with consideration of the natural history of each species, these changes in species composition and abundance appear to be related to alterations in vegetation structure caused by the hurricane. Every opportunity to study hurricane effects should be taken advantage of to gain a clearer understanding of the processes by which hurricane mediated changes in vegetation structure affect the species composition and dynamics of frog assemblages.

Acknowledgments.—I thank the Conservation Division of the Forestry Department, Ministry of Natural Resources of Belize for issuing research permits (CD/60/3/00, CD/60/3/01, and CD/60/3/02), and Peace Corps-Belize and the Belize Zoo for allowing me the time and flexibility to conduct this study. Many thanks to J. Arrigoni, J. and K. Marlin, and to field assistants including A. Canti, K. McLennan, D. O'Brien, N. Odedra, A. Requena, W. Requena, and P. Shol. I received valuable comments on previous drafts from R. Alford, W. Gibbons, R. Heyer, N. Karraker, J. Lee, D. Matlaga, and several anonymous reviewers. I am grateful to the Student Research Fund at the University of Wisconsin-Stevens Point and a DAPTF Seed Grant for funding during the research and for an EPA-GRO fellowship while writing the manuscript.

Geckos of the genus *Gonatodes* are small lizards measuring less than 130 mm total length. This genus contains 19 known species, all of which are Neotropical (Cole and Kok 2006; Kluge 2001; Powell and Henderson 2005), except *G. albogularis*, which was introduced to southern Florida, USA (Carr 1939). Eleven species of *Gonatodes* have been reported in Venezuela, and at least six more are being described (Barrio-Amorós and Brewer-Carías 2006; W. Schargel and G. Rivas, unpubl. data; C. Rivero-Blanco, pers. comm.). Most *Gonatodes* are arboreal; however, some could be accurately categorized as semi-arboreal or even terrestrial (e.g., *G. antillensis* and *G. albogularis bodinii* are mostly ground dwelling; Rivero-Blanco 1964). Other distinctive characteristics of these geckos are the round pupils and diurnal habits of most species (the exception being *G. antillensis*, the only species with oval pupils and mostly crepuscular or nocturnal habits). Aside from this information, the systematics, distribution, and biogeography of most species are poorly understood and merit comprehensive studies. Likewise, the natural history has only been studied in a few taxa (Duellman 1978; Murphy 1997; Quesnel et al. 2002; Rivas and Molina 2004; Seifan et al. 2002; Vitt et al. 1997, 2000). All taxa exhibit sexual dichromatism. In most cases, color-pattern differences between males and females are quite obvious. Yet, the coloration and pattern variation exhibited by males of many species is greater than previously reported and has been incompletely or poorly described.

Gonatodes ceciliae is endemic to the Península de Paria in extreme northeastern Venezuela and to the island of Trinidad (Rivero-Blanco 1979). It inhabits forested areas but little is known about its natural history. Limited data on its behavior and habitat were presented in the original description by Donoso-Barros (1966), and Murphy (1997) briefly described the natural history of populations in Trinidad. Rivero-Blanco (1979) described the Trinidadian population as a different subspecies; however, McBee et al. (1987) reported that *G. ceciliae* from the same locality (Simla, Arima Valley, Trinidad) had two different karyotypes, suggesting that there are two or more sympatric species.

Gonatodes vittatus is a common species known to occur in northern Colombia, northern Venezuela, and on the islands of Trinidad and Tobago, as well as many islands off the Venezuelan coast (e.g., Aruba, Curaçao, Los Roques, La Tortuga, Los Frailes, Isla de Margarita, Isla de Coche, Cubagua, and Los Testigos; Rivero-Blanco 1979). Although *G. vittatus* is a common species, little information has been reported about its natural history (e.g., Demeter and Marcelini 1981; Murphy 1997; Quesnel 1957; Roze 1964). Marcuzzi (1950) examined specimens from several localities in Venezuela and reported on their ecology and morphological and color variation. Although Marcuzzi (1950) provided an exhaustive description of the patterns of several specimens, most (if not all) of that information was based on preserved material. Moreover, Marcuzzi (1950) did not examine geckos from western Venezuela, thus the full spectrum of chromatic variation was incompletely documented. Later Rivero-Blanco (1979) provided a description of the species and additional information on its natural history.

Here we provide additional data on the natural history (distribution, habitat, behavior, reproduction, and predation) of these two species of *Gonatodes*, and describe color pattern variations in male *G. vittatus*.

All observations were made in the field. Illustrations were based on photographs taken of live geckos in the field. Illustrations were prepared using watercolor, ink, and color pencil. Collected geckoes were fixed in 10% formalin, transferred for preservation in 70% ethanol, and deposited in the herpetological collection of the Museo de Historia Natural La Salle (MHNLS), Caracas, and Museo de Biología, La Universidad del Zulia (MBLUZ), Maracaibo (Appendix).

Data for *Gonatodes ceciliae* were collected in deciduous, semideciduous, or cloud forest from four localities on the Península de Paria, Sucre: Locality 1) path between Puesto de Guarda Parques Las Melenas and Cerro Humo, southern versant of Península de Paria (10°39'N; 62°34'W; 700–800 m elev.), 1–2 June 2002; Locality 2) Guiria-Macuro road (10°39'N; 62°09'W; 15 m elev.), 3 June 2002; Locality 3) path between Macuro and Cerro Azul (10°40'N; 61°55'W; 400–600 m elev.), December 2003; Locality 4) Ensenada de Uquire, northern versant of Península de Paria (10°42'N; 61°58'W; 0 m elev.), August 1998.

Donoso-Barros (1966) noted that *Gonatodes ceciliae* is found beneath tree bark or in holes near the protruding buttresses of trees, and tends to inhabit houses. At Locality 1, eight individuals (seven males, one female) were found under rocks at 0900 h. When first discovered, these geckos remained motionless. Another female was found in the stump of a cut tree in the middle of a cleared patch of forest at midday. Nearby, a few geckos were found active on the forest floor at 2000 h during a full moon. In a neighboring forest patch, approximately 10 eggs were found at ground level under small stone slabs, in leaf-litter, and close to the base of a rocky wall. Donoso-Barros (1966) mentioned that *G. ceciliae* laid eggs in June in tree cavities and wall crevices. Here also we collected two species of snakes, *Liophis reginae zweifeli* and *Taeniophallus nebularis*, which are potential predators of *G. ceciliae*.

At Locality 2, *G. ceciliae* were found less than 0.5 m aboveground under fallen trees or logs or at the base of trees or palms. In one case a pair was found on the same trunk. This area had a strong marine influence, exemplified by the presence of terrestrial crabs (*Cardisoma* sp.), which are potential predators of *G. ceciliae* in that area. Three other species of geckoes inhabit the

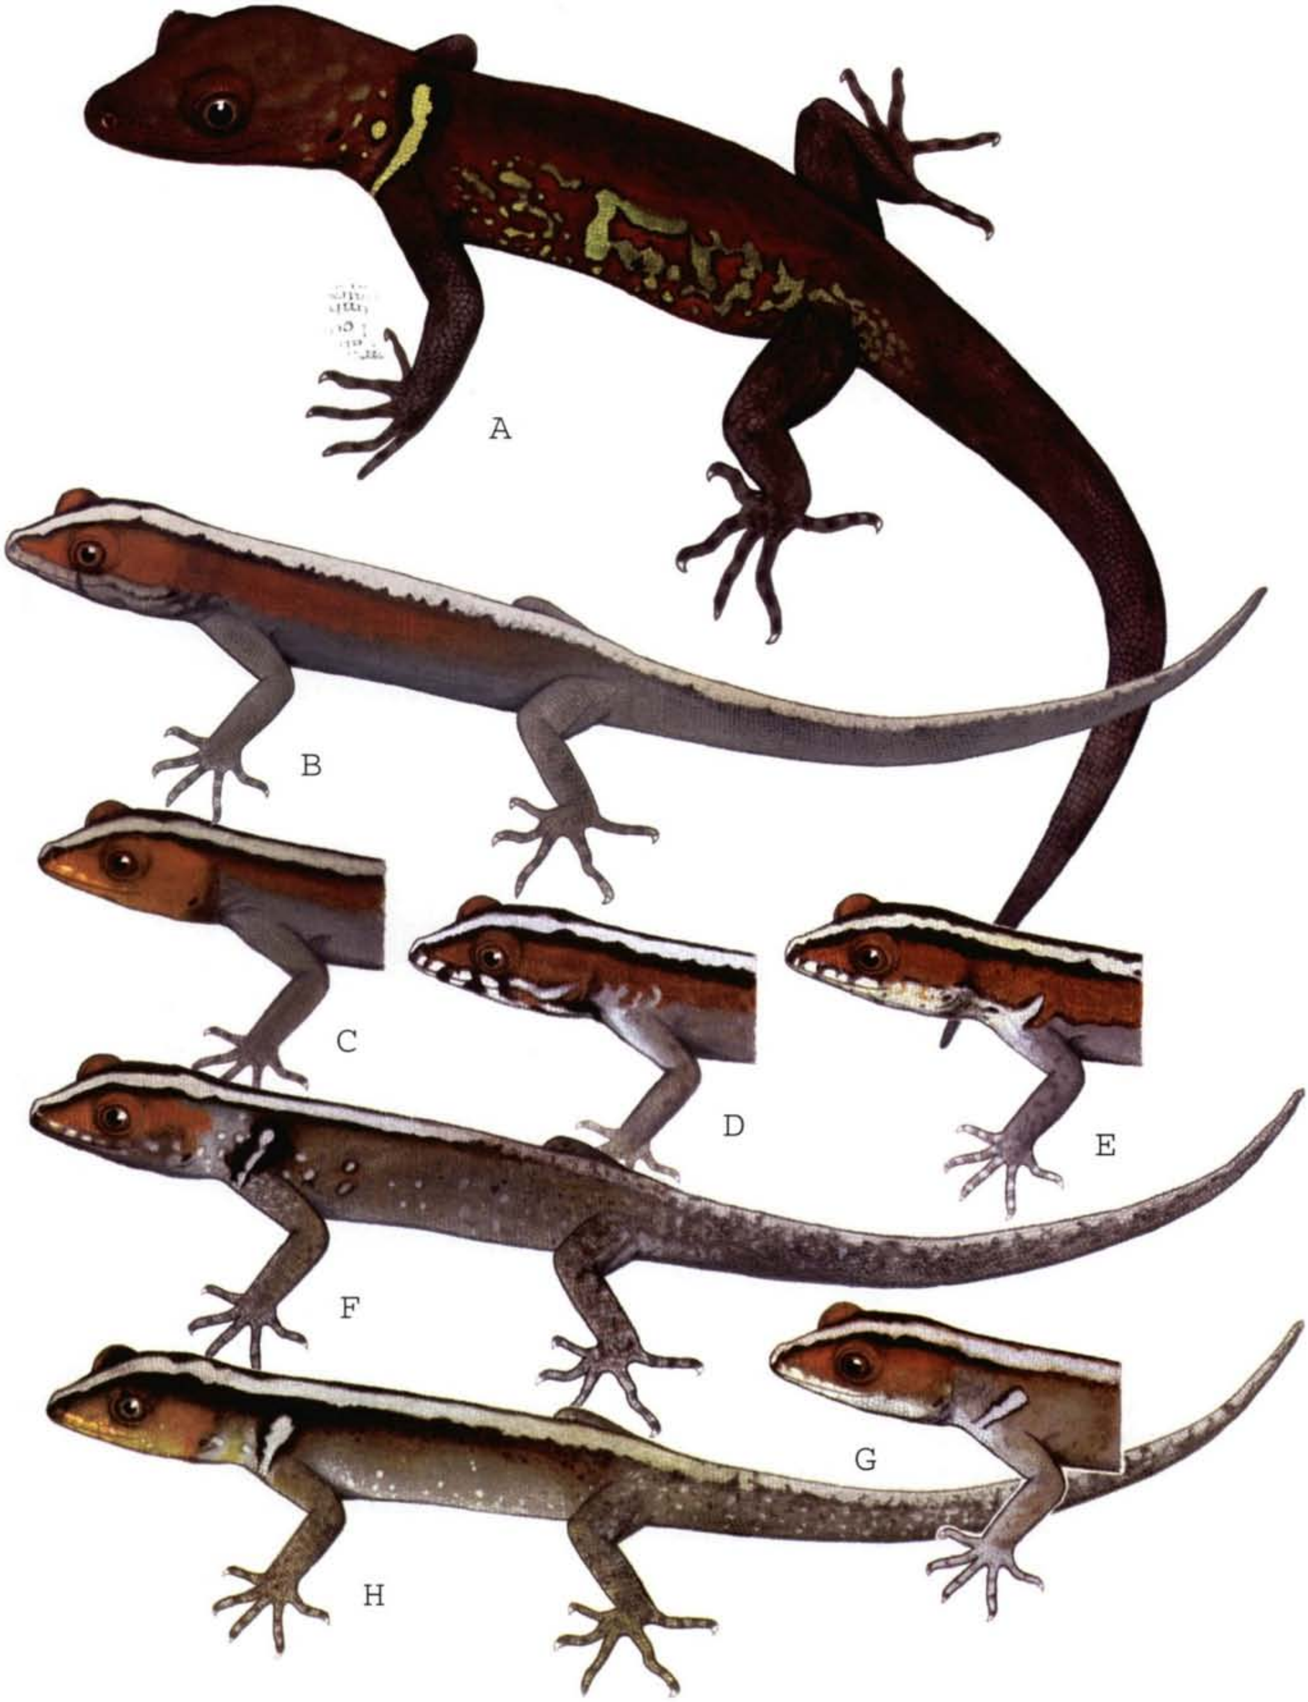

FIG. 1. Illustrations of adult male *Gonatodes* from Venezuela. (A) *G. ceciliae* Las Melenas, Península de Paria, estado Sucre; (B–H) *G. vitattus*: (B) Macuro, Península de Paria, estado Sucre; (C, D) Ocumare de la Costa, estado Aragua; (E) Sierra de Périja, estado Zulia; (F) Hacienda El Mirador, cerca de Casigua-El Cubo, estado Zulia; (G) La Azulita, estado Mérida; and (H) San Felipe, carretera entre Merida y Hacienda La Victoria, Sur del lago de Maracaibo, estado Merida.

area: the tiny *Sphaerodactylus molei*, which was found in a bromeliad on a tree trunk at this site (about 1.8 m above ground), *Thecadactylus rapicauda*, and *G. vittatus*.

Along a transect from near Macuro (40 m elev.) to midway to Cerro Azul at Locality 3, we observed *G. ceciliae* in a variety of microhabitats, but primarily in structures like water pipes and walls, as well as on an abandoned wooden cabin at 600 m elev., where the geckos were found on walls and beneath rocks. At a lower elevation (10 m elev.) near Macuro, we found *G. vittatus* in sympatry with *G. ceciliae* (always in association with human habitation and tree trunks in gardens) and the geckos *Hemidactylus palaichthus* and *T. rapicauda* (in association with an enclosed pool of water). At about 600 m, in a small cave in the rainforest, we found a communal nest site of *G. ceciliae* with the remains of hundreds of hatched eggs in an area of approximately 1 m^2. Communal nests are known for many other species of *Gonatodes* (Oda 2004; Quesnel 1957; Rivero-Blanco 1964), but this high density of eggs indicates the continued use of this nest for an extended period.

At Uquire (Locality 4), *G. ceciliae* was found at or near ground level in both abandoned and inhabited buildings (cabins, old houses). This species appears to show less of a preference for trees than other species of *Gonatodes*, although a single adult male was found about 1.5 m above ground. *Gonatodes vittatus* were observed at this locality as well.

Field data for *Gonatodes vittatus* were collected in the following localities: Turiamo and Ocumare de La Costa (Aragua); Guarenas, Urbanización El Placer, Prados Del Este (Miranda); Playa Guacuco, Isla de Margarita (Nueva Esparta). These localities varied from somewhat disturbed to residential or suburban and ranged in elevation from about 0–1000 m.

Males from several localities in the Distrito Capital and the states of Miranda, northern Aragua, northern Anzoategui, and Sucre (Península de Paria) exhibited the following coloration: Head and paravertebral areas of dorsum bright to dull orange, red-orange, or yellow-orange, with slightly lighter coloration on the sides of the head than on the body. Also, the orange in these areas sometimes varied in intensity, being somewhat darker or even brownish-orange in some specimens. Most variation among males in this region occurred in the color and pattern on the lips, chin, and throat. Some males had either uniformly yellow-orange or yellow-orange lips and throat with slightly darker but inconspicuous longitudinal stripes that converged midventrally. Others had bright white or pale gray lips, chin, and throat with distinct black stripes that started obliquely on the posterior supralabials (and/or below the eye) and extended to the throat where they formed a complex pattern that converged midventrally. However, the intensity, and especially the shape of these black stripes varied greatly. In a few individuals, the throat appeared black with oblique white stripes. In most individuals the stripes converged midventrally, but others had a more conspicuous vermiculate pattern, and still others had almost parallel stripes. A few males had uniformly gray lips and chin (clearly contrasting with the rest of the head), whereas the throat was whitish-gray with some longitudinally elongate black spots that converged midventrally. Dorsally, the orange coloration faded at different points along the body. In some specimens, this coloration reached the base of the tail but, more commonly, the orange faded immediately anterior to the insertion of the hind legs. All males examined had a distinct white vertebral stripe running longitudinally along their back, which extended from the tip of the snout to the tip of the tail. This stripe was usually well defined on the head and on the anterior portion of dorsum, but faded and became slightly darker posteriorly. This stripe occasionally had irregular margins and was usually narrower on the tail. A narrower black stripe paralleled the white stripe and was more distinct on the head and anterior part of the body before fading or, more frequently, fragmenting into irregular spots posteriorly. Black margins were usually not present on the tail or, when present, appeared as inconspicuous, short narrow lines. The rest of the dorsum, flanks, limbs, and tail were light gray or bluish-gray with no distinct markings, or were speckled with inconspicuous minute dark and light dots. In a male from Ocumare de La Costa, Aragua (Fig. 1C), the gray lateral color interrupted the orange area on the neck and touched the black stripes. A faint orange tint was present on the dorsal thighs of a few specimens. Digits had inconspicuous dark rings. The abdomen was generally as gray as the flanks; however, many individuals had a large black or blue-black area laterally extending from just anterior to the cloaca to the axilla along the flanks. In another male (Fig. 1D) from Aragua, the black color also extended onto parts of the chest, but most males lack these black areas.

A distinctive pattern was observed in males from Onia Ranch, near Vigia, Mérida State, South Maracaibo Lake Basin (SMLBa; Fig. 1H) and one from La Azulita, Mérida (SMLBb; Fig. 1G). This pattern may be restricted to individuals from these areas. At these localities the white vertebral stripe with black margins was distinct on the head and neck (also wider on this area). In the individual from Mérida and in one of the males from SMLBa (Fig. 1H), the vertebral stripe was less distinct on the back beyond the level of the arms, but remained more or less distinct to the tip of the tail. The specimen from SMLBb had an indistinct stripe that disappeared completely on the dorsal aspect of the last third of the tail (although this may be attributable to a regenerated tail). The black margins disappeared completely or faded on the back (beyond the level of the forelimbs) in all specimens but on the male from SMLBb, there were pairs of black, irregular, and inconspicuous spots along the vertebral stripe (pair on sacrum most distinct). The vertebral stripe was bordered instead by very narrow, irregular, and orange areas that disappeared midway along the back in the male from La Azulita, Mérida. The lips, chin, and throat of these individuals were uniformly white (or gray with darker stripes in one male from SMLBa; MBLUZ 828). A male photographed from the same general area had orange-yellow lips and chin. A black-bordered, oblique, white band was present just before the insertion of the arms and extended to the scapular area. The black margins of the humeral stripe in the specimen from SMLBa merged with the black margin of the vertebral stripe. The rest of the dorsum, tail, and limbs were slate-gray or brownish-gray with no distinct markings except for some inconspicuous orange smudges on the limbs and on the dorsum in the male from La Azulita. The other two individuals (SMLBa and SMLBb) had small, round, white spots or ocelli on the sides of the neck, flanks, and on the tail. The white ocelli near the axilla on the specimen from SMLBa had narrow and inconspicuous black margins. Digits had dark rings on a pale background in all specimens.

Two males from Aragua (Fig. 1C, D) matched in color and pat-

tern with the specimens from the Cordillera de la Costa Central and Península de Paria, but had an oblique, white and black-bordered stripe anterior to the insertion of the limbs that resembled the markings of males from SMLBa and La Azulita. Marcuzzi (1950) reported that this humeral stripe was observed in many males from Santa Ana, Península de Paraguana (Falcón), one male from La Cabrera, Lago de Valencia (Carabobo), and one male in Caracas (Distrito Capital). The white humeral stripe has not been observed in specimens east of Miranda state.

Gonatodes vittatus was observed in a wide variety of disturbed environments in or near human habitation, as has been reported other *Gonatodes* species including *G. albogularis*, *G. humeralis*, *G. siegliei*, and *G. taniae* (Oda 2004; Rivero-Blanco 1968, 1979), and *G. ceciliae* (this study). Most individuals were observed perched vertically on walls head down, and never far ($\leq$ 1.5 m) from hiding places such as vegetation, or holes and cracks in rock, brick, or cement. Other individuals were observed on rocks or in piles of trash. On the back porch of a house in Ocumare de la Costa (Aragua state), one male and two females were seen on logs lying on a cement floor and two other individuals were nearby. In less disturbed areas, *G. vittatus* was observed on shrubs, on the bases of tree trunks, or occasionally on the ground. When on tree trunks, geckos took refuge under loose bark or descended to shelter beneath vegetation or rocks at the base of the tree.

As is the case with other *Gonatodes* (Rivas and Molina 2004) we commonly observed this species in pairs or small groups, which were usually composed of a single male and one or two females. Juveniles were also occasionally found in the territories of adults, which is usually a wall or one or two trees (Roze 1964). We have observed adults (both sexes) with territories as small as 1–2 m^2. On a single stonewall ca. 4.5 × 2.5 m in Urbanización El Placer, Miranda, 26 individuals were counted in one afternoon.

Based on our observations, both males and females appear to be territorial, and we frequently observed individuals of both sexes chasing each other on walls. Territorial displays in males consisted of raising the head slightly and raising and waving the tail from side to side, movements also reported in other species of *Gonatodes* (Demeter and Marcelini 1981). Murphy (1997) noted that *G. vittatus* curls its tail in a "scorpion-like fashion," and reported a female displaying such posture toward a male right before the latter displaced the female from her station. We observed the 'tail-waving' display during presumably stressful situations or territorial interactions (see also Demeter and Marcelini 1981). Usually this display was followed by one individual chasing the other. No biting or other physical contact was observed.

Hemidactylus mabouia and *Thecadactylus rapicauda*, larger and more aggressive geckos, occur sympatrically with *G. vittatus* at numerous localities. No cases of predation by any of these geckos were observed, but Rivas et al. (2005) noted that populations of *G. vittatus* have decreased in number while populations of introduced *H. mabouia* have expanded in urban areas.

On the rocky slopes next to a small but heavily traveled road in Prados del Este, Caracas, a young Brown Vinesnake (*Oxybelis aeneus*, 580 mm total length) was observed preying on an adult male *G. vittatus* at 1130 h. The snake was perched on a small shrub overhanging the rock on which the gecko was moving. The gecko appeared not to notice when the snake slowly approached from above, suspending the anterior part of its body right above the lizard's body. After a short period during which the snake remained motionless, it struck suddenly at the middle of the lizard's body. The snake released its prey when handled and the gecko fled, showing no signs of physical damage or envenomation.

Acknowledgments.—We thank A. Bauer and K. Krysko for reading and commenting on an early version of this manuscript and W. Schargel for photographs and comments. Funds for Rivas and Barrio-Amorós to work in the Península de Paria and Maracaibo Lake were provided by H. Kaiser and W. McCord, respectively. Collection permits (01-11-0510 and 01-0590) were issued by the Ministerio del Ambiente y los Recursos Naturales (MARN) through the Fundación La Salle de Ciencias Naturales, Caracas. Finally, R. Powell and R. Espinoza made valuable suggestions, which considerably improved the manuscript.

All 12 species of map turtles show sexual size and trophic dimorphism. Females are much larger than males and have wider heads, even as juveniles that overlap adult males in body size (Gibbons and Lovich 1990; Lindeman 2000a). The sexes occupy different feeding niches (Lindeman 2000a). Head width evolution is correlated with evolution of alveolar width in females, presumably because of dietary preferences for mollusks in many species (Lindeman and Sharkey 2001). For males, however, changes in head width and alveolar width are unrelated, probably because males are more insectivorous (Lindeman and Sharkey 2001). The 12 species of *Graptemys* are classified as megacephalic, mesocephalic, or microcephalic based on female head width relative to body size, which is related to the degree to which females rely exclusively on mollusks (Lindeman 2000a).

Body size influences the size of molluscan prey consumed by map turtles. Adult male and juvenile female *Graptemys ernsti* consumed mainly arthropods, whereas adult females consumed mainly mollusks (Shealy 1976). Large females ate Asian clams (*Corbicula* sp.) almost exclusively and maximum clam size increased with female body size (Shealy 1976). Lahanas (1982) found a strong positive correlation between carapace length of *Graptemys nigrinoda* and length of their mytilid mussel prey *Modiolus*.

The sister taxon to *Graptemys* is the Diamondback Terrapin (*Malaclemys terrapin*; Stephens and Wiens 2003). Female *M. terrapin* had wider heads and larger body sizes and consumed proportionally more large Periwinkle Snails (*Littorina irrorata*) than males (Tucker et al. 1995).

Many eastern North American rivers within the range of species of *Graptemys* began to be invaded by Asian clams (*Corbicula* spp.) in the 1950s (McMahon 1982) and *Corbicula* has become a prominent component in the diets of several map turtle species (Lindeman 2000b, 2006; Moll 1980; Shealy 1976; Shively and Vidrine 1984). The Texas Map Turtle (*Graptemys versa* Stejneger 1925) is endemic to the Colorado River drainage of central Texas. The diet of adult female *G. versa*, once varied with only a moderately heavy reliance on native sphaeriid clams, now consists almost exclusively of Asian clams (Lindeman 2006).

We tested the hypothesis that body size and trophic morphology of female *G. versa* determine the size of molluscan prey they consume. We also examined the correlation of variation in prey size with female body size to test the hypothesis that prey size is more variable in larger females because their trophic morphology enables them to consume larger prey. Finally, we tested the hypothesis that residual head width and residual alveolar width (after removal of the effect of body size) influence prey length. These last analyses have not been part of previous examinations of molluscan prey size in *Graptemys* spp. or *Malaclemys terrapin* (Lahanas 1982; Shealy 1976; Tucker et al. 1995) and further refine our understanding of morphological adaptations related to feeding in these turtles.

Samples of feces and stomach contents containing $\geq$ 1.0 ml of *Corbicula* shells that had been collected in 1998 and 1999 from *G. versa* from the South Llano River in south-central Texas were pooled by individual turtle for analysis. All samples came from female turtles, as males are considerably smaller than females on average, have narrower heads and alveolar surfaces, and consumed few *Corbicula* (Lindeman 2006). Complete dietary data are presented elsewhere (Lindeman 2006); here we focus on the size of *Corbicula*. Plastron length (PL), head width (HW), and alveolar width (AW) of the upper jaw of each turtle were recorded following Lindeman (2000a; measurements taken by PVL). Length of *Corbicula* was measured to the nearest 0.1 mm along the long axis of the shell with dial calipers (measurements taken by DC). Shell lengths of fragmented shells were estimated by extrapolation to missing parts of the shell when possible. Data were tested for normality using the Kolmogorov-Smirnov test and correlation analysis was used to analyze the relationships of overall mean, upper quartile mean, and maximum shell length with PL, HW, and AW. Upper quartile mean and maximum size were included

because the constraints of head and alveolar width on prey size may be important only for the largest prey taken. Data were log-transformed prior to analysis to assess allometry of prey size.

The coefficient of variation (CV) for shell length was determined for each sample and the correlation of arcsin-square root transformed CV with log(PL) was examined to determine whether larger females consumed shells of more variable sizes. Residuals analyses were conducted on log-transformed data to test whether overall mean, upper quartile mean, and maximum shell length were related to HW and AW after adjusting for female PL. These analyses tested the hypothesis that females of a given body size with wider-than-expected head or alveolar surfaces would consume larger clams than their body size alone would predict.

Fourteen samples, from female turtles ranging in size from 74–149 mm PL, contained 1.0 ml or more of *Corbicula* shells. Sample size of clam shells was log-transformed to achieve normality. Log-transformed data on clam shell size and turtle morphology were also found to be normally distributed in Kolmogorov-Smirnov tests (all $P > 0.50$). Samples contained 12–93 (mean = 35.9) clam shells for which length could be measured directly or estimated, with no

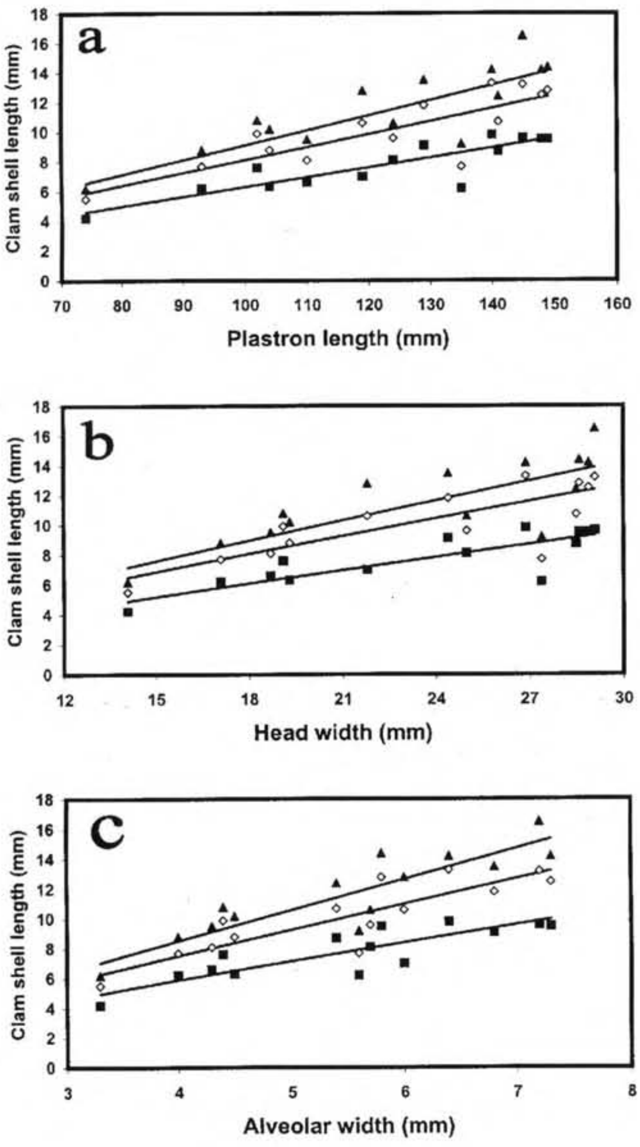

FIG. 1. Correlation of *Corbicula* shell length with measurements of (a) plastron length, (b) head width, and (c) alveolar width in female *Graptemys versa*. From top to bottom in each panel, lines represent back-transformed regressions of log-transformed maximum (triangles), upper quartile mean (diamonds), and overall mean (squares) shell length of *Corbicula* on log-transformed turtle body-size variables. All relationships were significant at $P < 0.001$.

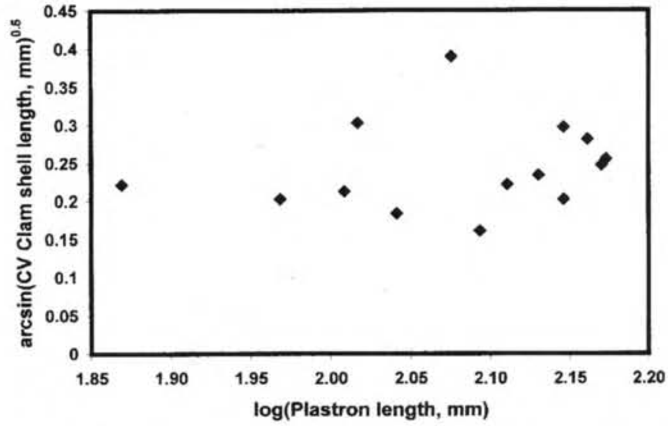

FIG. 2. Nonsignificant correlation of the arcsin-transformed coefficient of variation (CV) in clam shell length with female plastron length ($P = 0.53$, with the latter variable log-transformed for analysis).

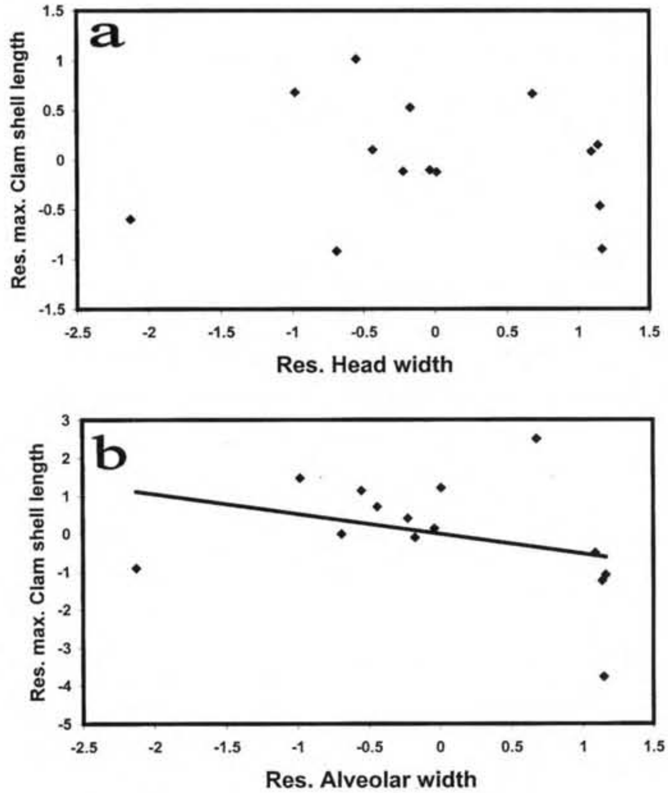

FIG. 3. Results of residual analyses testing (a) whether maximum shell length was related to head width (HW) after correction for both variables' log-log correlation with plastron length ($r = 0.335$, $P = 0.24$) and (b) whether maximum shell length was related to alveolar width (AW) after correction for both variables' log-log correlation with plastron length ($r = 0.575$, $P = 0.032$).

correlation found between plastron length and log-transformed sample size of clam shells (r = 0.013, P = 0.97). Log-transformed overall mean, upper quartile mean, and maximum shell length were all found to be strongly positively correlated with log-transformed turtle PL, HW, and AW (all $P < 0.001$; Table 1, Fig. 1). The relationships of clam shell length to turtle morphometric variables were not significantly different from isometry based on 95% confidence intervals on log-log slopes, as these all included the value of 1.00 that would be expected under isometry (Table 1).

TABLE 1. Results of correlation analyses relating length (mm) of *Corbicula* shells to morphometric data for 14 female *G. versa*. All data were log-transformed prior to analysis.

Independent variable (mm)	Dependent variable	r^2	Intercept	Slope (95% confidence interval)
Plastron length	Maximum	0.75	-1.22	1.09 (0.69–1.49)
	Upper quartile mean	0.72	-1.21	1.06 (0.64–1.48)
	Overall mean	0.77	-1.28	1.04 (0.68–1.40)
Head width	Maximum	0.67	-0.19	0.91 (0.51–1.31)
	Upper quartile mean	0.64	-0.21	0.89 (0.47–1.30)
	Overall mean	0.71	-0.32	0.88 (0.53–1.23)
Alveolar width	Maximum	0.80	0.34	0.98 (0.67–1.29)
	Upper quartile mean	0.76	0.31	0.94 (0.61–1.28)
	Overall mean	0.73	0.24	0.88 (0.54–1.22)

Coefficient of variation (arcsine-square root transformed) of clam shell length was not significantly correlated with log(PL) ($P = 0.53$; Fig. 2). Residuals analyses tested whether overall mean, upper quartile mean, or maximum clam shell lengths were related to residual HW after correction for both variables' correlation with plastron length; all had negative nonsignificant slopes (all $P \geq 0.20$; Fig. 3a). Residuals analyses testing the same relationships using residual AW all had positive correlation coefficients that were not significant for overall mean length ($P = 0.23$) and upper quartile mean length ($P = 0.101$), but significant for maximum shell length ($P = 0.032$; Fig. 3b).

Female *G. versa* have relatively wide heads and alveolar surfaces and their diet consists mainly of Asian clams (Lindeman 2000a, 2006). Plastron length, head width, and width of the alveolar surfaces of the upper jaw were all positively correlated with the size of Asian clams consumed. The lack of correlation between the coefficient of variation and plastron length may indicate that the larger female turtles preferentially take larger clams, which would provide more nutrition than smaller clams. Shealy (1976) found that the greatest ranges in *Corbicula* shell sizes ingested by *G. ernsti* were associated with large females but did not examine variance in shell sizes consumed.

The present study demonstrates that both body size and trophic morphology of map turtles influence the size of molluscan prey consumed and confirms the importance of trophic morphology in adapting these turtles to select molluscan prey (Lindeman 2000a; Lindeman and Sharkey 2001). The isometric relationship of prey size to turtle dimensions suggests a simple biomechanical relationship: enlarged body size, head width, and alveolar surface width allow larger prey to be consumed. In residuals analyses, female turtles with narrow alveolar surfaces relative to body size had relatively small maximum prey size and females with wide alveolar surfaces relative to body size had relatively large maximum prey size. Similar results were not obtained for upper quartile and mean shell sizes or for any residuals analyses using head width. Relative alveolar width may thus be more important than relative head width in determining the size of prey that can be ingested, with the constraint being greatest for maximum prey size.

Acknowledgments.—We thank T. Allen, L. Arkwright, D. Edwards, J. Lovell, and L. Lovell for their assistance in the field. The manuscript was reviewed by T. Tucker and D. Moll prior to submission for publication.

sures 375 mm snout–vent length, 53 mm tail length, and has 25-25-19 scale rows, 197 ventrals, 36 subcaudals, eight spot rows at midbody, 41/42 body and 9/9 caudal spots at dorsal midline, and external pelvic spurs. A female specimen (CZACC 4.11995) collected from Marianao, Havana City Province measures 372 mm SVL, 52 mm tail length, and has 25-25-21 scale rows, 196 ventrals, 34 subcaudals, 10 spot rows at midbody, 58/61 body and 9/9 caudal spots at dorsal midline. The previously reported maximum SVL for this species is 327 mm (males) and 347 mm (females) (Hedges 2002. Bull. Nat. Hist. Mus. Lond. [Zool.] 68[2]:83–91). These new specimens also expand the known range of body spot counts at dorsal midline from 35–55 to 35-61 (Hedges, *op. cit.*).

Submitted by **MICHEL DOMÍNGUEZ** (e-mail: michel.dominguez@ecologia.cu, micdom2002@yahoo.es) and **LUIS V. MORENO**, División de Colecciones Zoológicas, Instituto de Ecología y Sistemática, Carretera de Varona km 3 1/2, Capdevila, Boyeros, A.P. 8029, C.P. 10800, Ciudad de La Habana, Cuba.

TROPIDOPHIS MORENOI (NCN). **SIZE RECORD.** Previously reported measurements for the two known specimens *T. morenoi* (Hedges et al. 2001. J. Herpetol. 35:615–617) are 295 mm snout–vent length (SVL) and 45 mm tail length (TL) (holotype CZACC 4.5492; Colecciones Zoológicas del Instituto de Ecología y Sistemática, La Habana, Ciudad de La Habana province, Cuba; ex-collection IB 2493 from ex-Instituto de Biología, Cuba) and 285 mm SVL and 44 mm TL (Paratype CZACC 4.5493; ex-collection IB 2942). The type locality of this species is Dolinas de Cueva de Humboldt, Caguanes, Villa Clara Province, Cuba (22°50'04"N, 80°12'02"W). This place belongs now to the Sancti Spíritus Province. An adult female *Tropidophis* (CZACC 4.12052) was collected by J. Salas (unknown date) from the same locality. It was identified by MD as *T. morenoi* on 20 January 2004, and is the first specimen of *T. morenoi* reported after the species description (Hedges et al., *op. cit.*). Measurements of this specimen are: 359 mm SVL and 57 mm TL, which exceeds the previous records by 64 mm SVL and 12 mm TL. Measurements of the head were not possible to determine because the head and neck are damaged. Other characters of color, scale counts, and measures conform to those of the type series.

Submitted by **MICHEL DOMÍNGUEZ** (e-mail: michel.dominguez@ecologia.cu, micdom2002@yahoo.es), **LUIS V. MORENO**, and **LOURDES RODRÍGUEZ SCHETTINO** (e-mail: zoologia.ies@ama.cu.), Instituto de Ecología y Sistemática, Carretera de Varona km 3 1/2, Capdevila, Boyeros, A.P. 8029, C.P. 10800, Ciudad de La Habana, Cuba.

TROPIDOPHIS PARDALIS (NCN). **SIZE RECORD.** In July 1968, LVM collected a male *Tropidophis pardalis* from "La Catalina," Güines, Havana Province, Cuba. This specimen (CZACC 4.12042; Colecciones Zoológicas del Instituto de Ecología y Sistemática, Cuba) measures 284 mm snout–vent length, 38 mm tail length, and has 23-25-18 dorsal scale rows, 156 ventrals and 28 subcaudals, six spot rows at midbody, and 42/44 body spots at dorsal midline. A second male, collected by Julio Novo (date unknown) from Atabey, Playa, Havana City Province, Cuba (CZACC 4.8554), has 139 ventrals. A third male, collected by L. R. Hernández from Loma de la Esperanza, Sierra Morena, Villa Clara Province, Cuba on 26 May 1975 (CZACC 4.12012), has 160 ventrals. The previously reported maximum SVL for males of this species is 264 mm (Hedges 2002. Bull. Nat. Hist. Mus. Lond. [Zool.] 68[2]:83–91). The additional specimens expand the range of variation in ventral scale counts from 140–157 to 139–160 (Hedges, *op. cit.*).

Submitted by **MICHEL DOMÍNGUEZ** (e-mail: michel.dominguez@ecologia.cu, micdom2002@yahoo.es) and **LUIS V. MORENO**, División de Colecciones Zoológicas, Instituto de Ecología y Sistemática, Carretera de Varona km 3 1/2, Capdevila, Boyeros, A.P. 8029, C.P. 10800, Ciudad de La Habana, Cuba.

GEOGRAPHIC DISTRIBUTION

Instructions for contributors to Geographic Distribution appear in Volume 37, Number 1 (March 2006). Please note that the responsibility for checking literature for previously documented range extensions lies with authors. Do not submit range extension reports unless a thorough literature review has been completed.

CAUDATA

AMBYSTOMA OPACUM (Marbled Salamander). USA: TENNESSEE: Hawkins Co.: Holston Army Ammunition Plant located in the Kingsport Quad (36°32'05"N., 82°36'51"W). 13 April 1996. Harvey Hammock and John E. Copeland. Austin Peay State University Museum of Zoology, APSU 18168. Verified by A. Floyd Scott. Adult specimen found beneath roots of fallen tree. New county record that extends the range of the species in Tennessee into the eastern portion of Hawkins Co. (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp.).

Submitted by **JOHN E. COPELAND,** Department of Mathematics and Natural Sciences, Lincoln Memorial University, Harrogate, Tennessee 37752, USA; e-mail: john.copeland@lmunet.edu.

CRYPTOTRITON ADELOS (Sierra Juarez Moss Salamander). MÉXICO: OAXACA: Municipality of San Bernardino, Sierra Mazateca, Puerto Soledad (18°9'N, 96°59'W), 2065 m elev. 6 February 1993. Luis Canseco Márquez. Museo de Zoología, Facultad de Ciencias, UNAM (MZFC 13311). Municipality of Santa María Pápalo, Peña Verde (17°50'N, 96°47'W), 2805 m elev. 1 June 1999. Luis Canseco Márquez. Escuela de Biología, Universidad Autónoma de Puebla (EBUAP 1097). Both verified by D. B. Wake and M. García-Paris. MZFC 13311 is first record for the Sierra Mazateca and a range extension of ca. 94 km N from the type locality and EBUAP 1097 is the second record for the Sierra de Juárez (48 km N type locality) and bridges a gap between the type locality and the Sierra Mazateca record (Papenfuss and Wake 1987. Acta Zool. Mex. 21:1–16; as *Nototriton adelos*). Both specimens

were found in cloud forest.

Submitted by **LUIS CANSECO MÁRQUEZ**, Departamento de Biología Evolutiva, Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México, A.P. 70-399, México, D.F. 04510, México; e-mail: lcm@correo.unam.mx.

NOTOPHTHALMUS VIRIDESCENS LOUISIANENSIS (Central Newt). USA: TENNESSEE: CHESTER CO.: Henderson, Freed-Hardeman University Campus (35°26.082'N, 88°38.038'W). 16 March 2006. Timothy Harris. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 18159, color photo). New county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp.).

Submitted by **TIMOTHY HARRIS** and **BRIAN P. BUTTERFIELD,** Department of Biology, Freed-Hardeman University, Henderson, Tennessee 38340, USA; e-mail: bbutterfield@fhu.edu.

PHAEOGNATHUS HUBRICHTI (Red Hills Salamander). USA: ALABAMA: WILCOX CO.: N31.9054°, W87.2505°. 12 October 2005. M. Bailey and M. Van Fleet. Verified by Craig Guyer. Photograph voucher deposited in the Alabama Herp Atlas Project at Auburn University (AUM-AHAP-37294). Adults were observed at burrow openings on an east-facing slope in second-growth mesic deciduous forest. This record represents the northernmost locality for the species and is a new county record (Mount 1975. The Reptiles and Amphibians of Alabama. Alabama Agricultural Experiment Station, Auburn University, Alabama. 347 pp.). The monotypic genus *Phaeognathus* was presumed to be limited to portions of the Tallahatta and Hatchetigbee geologic formations in five Alabama counties (Schwaner and Mount 1970. Copeia 1970:571–573). However, our new locality lies within the older Nanafalia geologic formation (LaMoreaux and Toulmin 1960. Geologic Map of Wilcox County, Alabama. Geological Survey of Alabama Co. Report 4) and is 13.5 km NE of the nearest mapped Hatchetigbee or Tallahatta formation (Scott 1971. Geologic Map of Monroe County, Alabama. Geological Survey of Alabama, Special Map 101). Topography and the vegetative community at this locality are virtually identical to occupied *Phaeognathus* habitats to the south, suggesting the new site might represent a disjunct population.

Submitted by **MARK A. BAILEY**, Conservation Southeast, 7746 Boggan Level Road, Andalusia, Alabama 36420, USA (e-mail: mbailey@conservationsoutheast.com); and **DARREN A. MILLER**, Weyerhaeuser Co., P.O. Box 2288, Columbus, Mississippi 39704, USA (e-mail: darren.miller@weyerhaeuser.com).

ANURA

BRACHYCEPHALUS EPHIPPIUM (Pumpkin Toadlet). BRAZIL: MINAS GERAIS: Municipality of Fervedouro: Mata do Pai Inácio, (20°46'S, 42°29'W, 1340 m elev.) Parque Estadual da Serra do Brigadeiro. December 2005. J. S. Dayrell, E. F. Oliveira, and R. N. Feio. Museu de Zoologia João Moojen de Oliveira, Universidade Federal de Viçosa, Minas Gerais, Brazil (MZUFV 6658–6662, 6671). Verified by J. P. Pombal-Jr. Published distribution for the species is Atlantic Forests in the states of Bahia, Espírito Santo, Rio de Janeiro, São Paulo, and Paraná, in eastern and southeastern Brazil (Pombal-Jr. 2001. Amphibia-Reptilia 22:179–185; Frost 2005. Amphibian Species of the World: An Online Reference. http://research.amnh.org/herpetology/amphibia). First state record and the most inland record for the species, extends its distribution 250 km NE from Nova Friburgo, RJ (Pombal-Jr., 2001, *op. cit.*).

Submited by **JUSSARA SANTOS DAYRELL, ELIANA FARIA DE OLIVEIRA, CARLA SANTANA CASSINI,** and **RENATO NEVES FEIO,** Museu de Zoologia João Moojen de Oliveira, Universidade Federal de Viçosa, 36571-00, Viçosa, MG, Brazil; e-mail jussaradayrell@gmail.com.

BUFO CAMERUNENSIS (Oban Toad). CENTRAL AFRICAN REPUBLIC: Ngotto Forest, Batouri River area (3°54'N, 17°2'E), bank of the Lobaye River, 445 m elev. This area consists of a mixed-species, semi-deciduous primary forest at the northern limit of the Guinea-Congolese rainforest. Between 25 November 1998 and 6 December 1999. P. Barrière. Verified by Alain Dubois. Muséum national d'Histoire naturelle, Paris (MNHN 2003.3380–3393). These 14 specimens (SVL 10–69 mm) were found dead in a pitfall trap used to collect terrestrial small mammals, during a long-term ecological and epidemiological survey within the Ecofac project (http://www.ecofac.org). First country record. Previously known from the forested areas of Guinea, Ivory Coast, Liberia, Nigeria, Cameroon, Equatorial Guinea, Bioko, Gabon, Republic of Congo, and Democratic Republic of Congo (Frost 2004. Amphibian Species of the World [online]. Ver. 3.0. American Museum of Natural History, New York; Frétey and Blanc 2000. Liste des Amphibiens d'Afrique centrale. Dossiers de l'ADIE, Série Biodiversité 2:1–39.).

Submitted by **THIERRY FRETEY**, Association Racine, 2 rue de la Cité, F–35360 Médréac, France (e-mail: fretey.thierry@wanadoo.fr); **PATRICK BARRIERE**, Laboratoire Ecobio: Ecosystèmes, Biodiversité et Evolution, UMR 6553-CNRS, Université de Rennes 1, Station Biologique, F-35380 Paimpont, France (e-mail: Patrick.Barriere@laposte.net); and **ANNEMARIE OHLER**, Muséum national d'Histoire naturelle, Département de Systématique et Evolution, USM 602 Taxinomie et collections (Reptiles et Amphibiens), 25 rue Cuvier, F-75005 Paris, France (e-mail: ohler@mnhn.fr).

BUFO WOODHOUSII (Woodhouse's Toad). USA: CALIFORNIA: RIVERSIDE CO.: Taylor Ferry Site, Imperial Co. line, Colorado River, 25 September 2004 (LACM 155888). Additional specimens: LACM 155080, LACM 155890, LACM 155875 (verified by Kent Beaman, LACM) and EJR7295–7299 (verified by Eric Routman, San Francisco State University). These specimens, which support an older voucher from 1967 (LACM 37772), were collected from southern to northern Riverside Co. and fill the distribution gap of *B. woodhousii* along the lower Colorado River in California (Sullivan et al. 1996. Copeia 1996:274–280). This distribution is consistent with the relatively recent expansion of *B. woodhousii* to the southwest (Masta et al. 2003. Mol. Ecol. 12:1541–1554).

Submitted by **DAVID M. GOODWARD,** 22430 Pico Street, Grand Terrace, California 92313, USA (e-mail:

davegoodward@earthlink.net); and **SUSAN E. MASTA,** Department of Biology, Portland State University, P.O. Box 751, Portland, Oregon 97207, USA.

CRYPTOTHYLAX GRESHOFFII (NCN). REPUBLIC OF CONGO: SANGHA: Mombongo, near Bomassa (02°12.50'N, 16°11.35'E), 72 m elev. 22 June 1997. Kate Jackson. Museum of Comparative Zoology, MCZ A-136000–2. Verified by José Rosado. Previously recorded in Angola, Cameroon, Central African Republic, Democratic Republic of Congo, Equatorial Guinea, and Gabon (de la Riva 1994. Rev. Esp. Herpetol. 82:123–139; IUCN et al. 2004. <www.globalamphibians.org>; Knoepffler 1966. Biol. Gab. 2:157–161; Laurent 1976. Ann. Mus. R. Afr. Centrale 213:1–67; Perret 1966. Zool. Jb. Syst. 8:289–464; Schiøtz 1999. Treefrogs of Africa. Edition Chimaira, Frankfurt am Main. 350 pp.). MCZ A–136000 (subadult, SVL 40.1 mm), 136001 (female; SVL 52.6 mm), and 136002 (male; SVL 45.0 mm) were collected between 2000–2200 h from vegetation ca. 1 m above the ground at the edge of the swamp at Mombongo. In life, specimens were rust colored; in ventral view, the belly and gular region were white with red arms and legs. Presence of this species in the Republic of Congo has been assumed but never documented. This is the first report of *Cryptothylax* from the Republic of Congo.

Submitted by **DAVID C. BLACKBURN**, Department of Organismic and Evolutionary Biology, Harvard University, 26 Oxford Street, Museum of Comparative Zoology, Cambridge, Massachusetts 02138, USA (e-mail: dblackb@fas.harvard.edu); and **KATE JACKSON**, Department of Zoology, University of Toronto, 25 Harbord Street, Toronto, Ontario, Canada (e-mail: kjackson@zoo.utoronto.ca).

HYLA SQUIRELLA (Squirrel Treefrog). USA: ALABAMA: CHAMBERS CO.: 5 km N of Waverly. UTM 16 632287E 36 27624N (WGS 84). 23 Aug 2005. Geoffrey G. Sorrell. Verified by Craig Guyer. AUM 37269. New county record (Mitchell and Lannoo 2005. *In* Lannoo [ed.], Amphibian Declines: The Conservation Status of United States Species, pp. 456–458. Univ. of California Press, Berkeley). The nearest record is from Lee Co., which neighbors Chambers Co. to the south. This specimen was collected from a roadside ditch along County Road 22 at ~2000 h. Approximately five other males were calling from the same location, which indicates presence of a breeding population.

Submitted by **GEOFFREY G. SORRELL**, Department of Biological Sciences, 331 Funchess Hall, Auburn University, Alabama 36849-5414, USA; e-mail: sorregg@auburn.edu.

HYPSIBOAS BECKERI (NCN). BRAZIL: MINAS GERAIS: SERRA DA PEDRA BRANCA: Pedralva Municipality (22°11'16.1"S, 45°23'23.5"W). 14 October 2005. V. G. D. Orrico and C. Luna-Dias. Herpetological Collection of the Departamento de Zoologia of Universidade Federal do Rio de Janeiro, Rio de Janeiro (ZUFRJ 9527, male and 9528, female). Verified by S. P. Carvalho-e-Silva. Previously known only from the type locality: Poços de Caldas, Minas Gerais (Caramaschi and Cruz 2004. Arq. Mus. Nac. Rio de Janeiro 62[3]:247–254). The new occurrence extends distribution 123 km ESE (straight line).

Submitted by **VICTOR GOYANNES DILL ORRICO** (e-mail: victordill@gmail.com) and **CYRO LUNA-DIAS NETO** (e-mail: cyroluna@gmail.com), Departamento de Zoologia, Universidade Federal do Rio de Janeiro, CP 68.044, CEP 21944-970, Cidade Universitária, Rio de Janeiro, Brazil.

LEPTOBRACHIUM MOUHOTI (NCN). VIETNAM: QUANG NAM PROVINCE: Ngoc Linh Mountain: Tra My District: Tra Don Commune (15°11.688'N, 108°2.413'E), 930 m elev. 10 March 1999. AMNH A-163651–163652 (15°11.507'N, 108°2.380'E), 960–990 m elev. 13 March 1999. AMNH A-163653 (15°10.698'N, 108°2.539'E), 1480 m elev. 20 March 1999. AMNH A-163649 (15°11.688'N, 108°2.539'E), 970 m elev. 22 March 1999. AMNH A-163650 (15°11.622'N, 108°2.212'E), 1020 m elev. 2 April 1999. AMNH A-163656–163657. Tra Tap Commune, near Thon 2 Village, stream (15°9.622'N, 108°2.427'E), 920–1060 m elev. 26–28 March 1999. AMNH A-163654–163655. All specimens collected by Nguyen Quang Truong. Verified by Bryan L. Stuart. This species is currently known only from the type locality in Mondolkiri Province, Cambodia (Stuart et al. 2006. Raffles Bull. Zool. 54[1]:129–155). This is the first record for Vietnam and extends the known range of this species by more than 300 km N from the southern Truong Son Mountains (Annamites) to the Central Truong Son. This also extends the elevational range of the species, as the type series was from 500–700 m.

Submitted by **RAOUL H. BAIN**, Center for Biodiversity and Conservation, American Museum of Natural History, Central Park West at 79th Street, New York, New York 10024, USA (e-mail: bain@amnh.org); and **NGUYEN QUANG TRUONG**, Department of Vertebrate Zoology, Institute of Ecology and Biological Resources, 18 Hoang Quoc Viet, Hanoi, Vietnam (e-mail: truong@iebr.vast.ac.vn).

LEPTOPELIS CALCARATUS (Efulen Forest Treefrog). CENTRAL AFRICAN REPUBLIC: Ngotto Forest, Batouri River area (03°54'N, 17°2'E), bank of the Lobaye River, 445 m elev. This area consists of a mixed-species, semi-deciduous primary forest at the northern limit of the Guinea-Congolese rainforest. Between 25 November 1998 and 6 December 1999. P. Barrière. Verified by Alain Dubois. Muséum national d'Histoire naturelle, Paris (MNHN 2003.3395). This specimen (SVL 48 mm) was found dead in a pitfall trap used to collect terrestrial small mammals, during a long-term ecological and epidemiological survey within the Ecofac project (http://www.ecofac.org). First country record. Previously known from the dense forested areas of Nigeria, Cameroon, Equatorial Guinea, Bioko, Gabon, and Democratic Republic of Congo (Frétey and Blanc 2000. Liste des Amphibiens d'Afrique centrale. Dossiers de l'ADIE, Série Biodiversité 2:1–39; Frost 2004. Amphibian Species of the World [online]. Ver. 3.0. American Museum of Natural History, New York).

Submitted by **THIERRY FRÉTEY**, Association Racine, 2 rue de la Cité, F-35360 Médréac, France (e-mail: fretey.thierry@wanadoo.fr); **PATRICK BARRIERE**, Laboratoire Ecobio: Ecosystèmes, Biodiversité et Evolution, UMR 6553-CNRS, Université de Rennes 1, Station Biologique, F-35380 Paimpont, France (e-mail: Patrick.Barriere@laposte.net); and **ANNEMARIE OHLER**, Muséum national d'Histoire naturelle, Département de Systématique et Evolution, USM 602 Taxinomie et collections (Reptiles et Amphibiens), 25 rue Cuvier, F-75005 Paris, France (e-mail: ohler@mnhn.fr).

LITHOBATES JOHNI (Moore's Frog). MÉXICO: PUEBLA: Municipality of Huehuetla: Río Tehuancate, under Tehuancate bridge, km 77 on Huehuetla-Zacapoaxtla Hwy (22°05'22.2"N, 97°36'36.4"W), 460 m elev. 7 June and 22 August 2003. Itzel Durán-Fuentes, Edmundo Pérez-Ramos, and Andrés A. Mendoza-Hernández. Verified by Luis Canseco-Márquez. Museo de Zool. "Alfonso L. Herrera," Fac. Cienc., UNAM (MZFC 17602–17607, 17609, 17611–17615). First record for Puebla, extending its known range ca. 145 km (airline) SE of Tehuatlán (Tehuetlán), Hidalgo (Webb 1988. Occ. Pap. Mus. Texas Tech Univ. [121]:1–15). The frogs were collected in and along the river situated in tropical semideciduous forest. The Global Amphibian Assessment (www.globalamphibians.org), accessed 27 February 2006, listed *L. johni* as an endangered species, although it was recently considered extinct by Hillis and Wilcox (2005. Mol. Phyl. Evol. 34:299–314). The above records and two others from Hidalgo (MZFC 14156–57) substantiate the viability of this species in east-central México.

Submitted by **ITZEL DURÁN-FUENTES, EDMUNDO PÉREZ-RAMOS,** and **ANDRÉS ALBERTO MENDOZA-HERNÁNDEZ,** Museo de Zoología, Facultad de Ciencias, UNAM, A.P. 70-399, México D.F. 04510, México (e-mail [IDF]: itzeldf@gmail.com).

PIPA PIPA (Surinam Toad). ECUADOR: PROVINCIA DE PASTAZA: Shiripuno River, Ñoneno area (01°05'S, 77°03'W, ca. 300 m elev.). 30 August 1997. J. -M. Touzet. Universidad San Francisco de Quito/Fund. Herpetológica Orcés, Quito (FHGO-USFQ 1650). Verified by Jean-Marc Touzet. *Pipa pipa* is a widely distributed species in the Amazonian basin from Venezuela to Bolivia and Brazil, the Guianas region and Trinidad (Frost 2002. Amphibian Species of the World: an Online Reference. V2.21 [15 July 2002] <http://research.amnh.org/herpetology/amphibia/index.html> [Accessed: 19 July 2004]). However, this aquatic frog has been reported from just three localities in Ecuador, in the provinces of Sucumbíos and Orellana (Duellman 1978. Misc. Publ. Univ. Kansas, Mus. Nat. Hist. 65. 352 pp.; Ron 2001. Anfibios de Parque Nacional Yasuní, Amazonía Ecuatoriana. Ver. 1.3 [2 March 2001]. Museo de Zoología, Pontificia Universidad Católica del Ecuador. Quito. <http://www.esb.utexas.edu/sron/ecuador/yasuni/esp/anfyas.htm> [Accessed: 19 July 2004]; Cisneros-Heredia 2003. *In* De la Torre and Reck [eds.], Ecología y Ambiente en el Ecuador. Mem. I Congreso de Ecología y Ambiente, Ecuador país megadiverso. CD. Universidad San Francisco de Quito, pp. 1–21). The specimen reported herein constitutes the first from the province of Pastaza and the westernmost record for the species, extending its range ca. 110 km ENE from previous localities in the province of Orellana, Ecuador (Yasuni Scientific Station and Tiputini Biodiversity Station; Ron, *op. cit.*; Cisneros-Heredia, *op. cit.*).

Submitted by **DIEGO F. CISNEROS-HEREDIA**, College of Biological and Environmental Sciences, Universidad San Francisco de Quito, Ave. Interoceánica y calle Diego de Robles, Campus Cumbayá, Edif. Maxwell, Casilla Postal 17-12-841, Quito, Ecuador; e-mail: diegofrancisco_cisneros@yahoo.com.

RANA AREOLATA (Crawfish Frog). USA: TENNESSEE: Gibson Co.: At the junction of Highway 425 and Milan Airport Road (UTM: 16S 0341238 3978775). 8 March 2006. Mandy Messer. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 18162, color photo). New county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp.).

Submitted by **MANDY MESSER, LAURIE BENNIE,** and **BRIAN P. BUTTERFIELD,** Department of Biology, Freed-Hardeman University, Henderson, Tennessee 38340, USA (e-mail: bbutterfield@fhu.edu).

RANA PALUSTRIS (Pickerel Frog). USA: TENNESSEE: Wayne Co.: Along Highway 64 E of Clifton Junction (UTM: 16S 0410825 3905480). 13 March 2006. Mandy Messer. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 18163, color photo). New county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp.).

Submitted by **MANDY MESSER, LAURIE BENNIE,** and **BRIAN P. BUTTERFIELD,** Department of Biology, Freed-Hardeman University, Henderson, Tennessee 38340, USA (e-mail: bbutterfield@fhu.edu).

RANA SYLVATICA (Wood Frog). USA: NORTH DAKOTA: McHenry Co.: 48°09'09.3"N, 100°55'03.8"W. 51 Street NW, Minot State University Applied Amphibian Field Ecology Lab, Schwabs Pond. 19 August 2005. Kenneth C Cabarle. Verified by Chris Beachy. Minot State University, Cyril Moore Science Center Research Collections (CMSCRCDF-2005-001). New record within McHenry Co. Adult individuals (N = 3) collected from pitfall traps at amphibian drift fence site, permanent pond in agricultural area. Adults appeared to be plentiful. This locality represents an extension within this county 120 km SW of the last recorded county record near Towner, North Dakota. The locality also extends collection records from a glacial basin eco-region to an adjacent glacial delta eco-region. This locality might expand the maximum southwestern distribution for the species with North Dakota (Redmer and Trauth 2005. *In* M. Lannoo [ed.], Amphibian Declines. The Conservation Status of United States Species, pp. 590–593. University of California Press, Berkeley and Los Angeles; Hoberg and Gause 1992. North Dakota Outdoors 55[1]:7–18.; and Johnson and Batie 1996. Surveys of Calling Amphibians in North Dakota. Jamestown, North Dakota: Northern Prairie Wildlife Research Center Online. http://www.npwrc.usgs.gov/resource/herps/amsurvey/amsurvey.htm (Version 16JUL97).

Special thanks to Minot State University and North Dakota INBRE for funding this research.

SCAPHIOPUS COUCHI (Couch's Spadefoot). USA: CALIFORNIA: Riverside Co.: 2 mi. SSE of Blythe, 33.5744°N, 114.5691°W, 13 August 1999. Tadpoles (MVZ 230247–50, verified by mtDNA sequencing, Paul Barber, Boston University); 1.2 mi. WNW of Palo Verde, 33.4345°N, 114.7481°W, 8 October 2004, toadlet

(LACM 155892). Additional specimens and photographs of adults: LACM 155877, 155887, 155889, LACM PC1417 and PC1418. Verified by Kent Beaman, Nat. Hist. Mus. of Los Angeles Co.) First county records (Glaser 1970. The Distribution of Amphibians and Reptiles in Riverside County, California. Riverside Museum Press, Riverside, California). These records are from extreme eastern Riverside County in and near the Palo Verde Valley, from the Imperial County border north to 20 miles NW of Blythe. This species has been presumed to occur in Riverside County, but documentation had been lacking.

BARBER**, Boston University Marine Program, 7 MBL Street, Woods Hole, Massachusetts 02543, USA (e-mail:pbarber@bu.edu); and **DANIEL R. BUCHHOLZ**, Department of Biological Sciences, University of Cincinnati, Cincinnati, Ohio 45221-0006, USA.

SCINAX NASICUS (Lesser Snouted Treefrog). ARGENTINA: BUENOS AIRES: PARTIDO DE LA PLATA: Cattle farming pasture (34º59'05"S; 57º51'21"W), 8 January 2006. G. S. Natale. Museo de Ciencias Naturales de La Plata, Buenos Aires (MLP 3504–05, 3507, two adult males and one female). PARTIDO DE ARRECIFES: soy culture field (34º6'46"S; 60º8'20'"W), 8 January 2003. G. S. Natale. MLP 3506. All verified by L. Alcalde. Known distribution ranges from Bolivia (De la Riva et al. 2000. Rev. Esp. Herpetol. 14:19–164), to Brazil in Matto Grosso and "Cerrado" regions including Rio Grande do Sul (Giasson 2001. Herpetol. Rev. 32:273; Cechin et al. 2002. Herpetol. Rev. 33:222), Paraguay (Aquino et al. 1996. Colección de Flora y Fauna del Museo Nacional de Historia Natural del Paraguay. Romero. Editor. pp. 331–400), and Uruguay (Langone 1994. Ranas y Sapos del Uruguay, Reconocimiento y Aspectos Biologicos. Museo Damaso Antonio Larrañaga -Divulgación 5:1–123). In Argentina, it is widespread in the central and northern regions from Jujuy to northern Buenos Aires (Faivovich 1994. Herpetol. Rev. 25:75; Lavilla et al. [eds.] 2000. Categorización de los Anfibios y Reptiles de la República Argentina. Asociación Herpetológica Argentina. Tucumán Argentina. 97 pp.). La Plata is the southernmost known record and extends the range 200 km SE from Baradero (Faivovich, *op. cit.*). The record from Arrecifes extends the distribution 68 km to the west, out of the coastal zone proposed as a faunal filter by Gallardo (1974. Anfibios de los Alrededores de Buenos Aires. Edit. Univ. Eudeba/Lectores. 231 pp.).

ZACHAENUS CARVALHOI (Carvalho's Bug-eyed Frog). BRAZIL: MINAS GERAIS: Municipality of Pedra Dourada: Fazenda Floresta (20°47'S, 42°10'W, 1087 m elev.) Área de Proteção Ambiental Municipal Pedra Dourada. December 2005. J. S. Dayrell and C. P. Neves. Museu de Zoologia João Moojen de Oliveira, Universidade Federal de Viçosa, Viçosa, Minas Gerais (MZUFV 6730–6731). Verified by U. Caramaschi. First record outside the type locality: Municipality of Santa Tereza, Espírito Santo (Izecksohn 1982. Arq. Univ. Fed. Rural Rio de Janeiro 5[1]:7–11; Frost 2000. Amphibian Species of the World: An Online Reference. http://research.amnh.org/herpetology/amphibia), first state record, and the most inland record for the species. Extends southwestern range ca. 170 km airline.

Submitted by **JUSSARA SANTOS DAYRELL, CHARLENE DA PENHA NEVES, CARLA SANTANA CASSINI,** and **RENATO NEVES FEIO,** Museu de Zoologia João Moojen de Oliveira, Universidade Federal de Viçosa, 36571-00, Viçosa, MG, Brazil (e-mail: jussaradayrell@gmail.com).

LACERTILIA

AGAMA AGAMA AFRICANA (African Rainbow Lizard). USA: FLORIDA: LEE Co.: Sanibel Island, 5424 Shearwater Drive (26.46602°N, 82.1583°W, NAD83). 5 May 2006. Chris Lechowicz and Malcom Harpham. UF 146784 (photographic voucher). Verified by Kenneth L. Krysko. New county record and ca. 55 km S of the closest known population in Punta Gorda, Charlotte County (Enge et al. 2004. Florida Sci. 67:303–310). Adult male on wall of private residence.

Submitted by **CHRISTOPHER J. LECHOWICZ,** Sanibel-Captiva Conservation Foundation, P.O. Box 839, Sanibel, Florida 33957, USA; e-mail: clechowicz@sccf.org.

BACHIA HETEROPA ALLENI (Earless Worm Lizard). ST. VINCENT AND THE GRENADINES: Mustique Island and Union Island. 20 May 2005. Mark de Silva. MPM 33973–74. Verified by S. B. Hedges. Both are new island records, although the species is known from elsewhere on the Grenada Bank. The species occurs on Bequia and Canouan in the Grenadines and on Grenada (Schwartz and Henderson 1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. Univ. Florida Press, Gainesville, i-xvi+720 pp.).

Submitted by **ROBERT W. HENDERSON**, Section of Vertebrate Zoology, Milwaukee Public Museum, Milwaukee, Wisconsin 53233, USA (e-mail: rh@mpm.edu); and **ROBERT POWELL**, Department of Biology, Avila University, Kansas City, Missouri 64145, USA (e-mail: powellr@avila.edu).

GEHYRA MUTILATA (Mutilated Gecko). INDONESIA: KRAKATAU ISLANDS: Coastal forest, east shore, Panjang Island (06°05'S, 105°25'E). 2 April 2001. Mark O'Shea. Collected from under the bark of *Casuarina* tree. Rawlinson Krakatau Collection at Museum of Victoria, Melbourne, photographic voucher (NMV D 72413). Verified by Hidetoshi Ota.

The volcanic eruption of 27 August 1883 extinguished all life from Krakatau and the neighboring islands of Sertung and Panjang (Thornton 1996. The Destruction and Reassembly of an Island Ecosystem. Harvard Univ. Press, Cambridge, Massachusetts, xii + 346 pp.). All that remained of the original Krakatau was the southern half of Rakata volcano, a small outcrop to the north called Bootsmanrots, and the neighbouring islands of Panjang and Sertung, with a 200-m deep submarine caldera separating them. In 1930, a new island, Anak Krakatau, arose in the northern section of the Krakatau caldera.

Reptiles began to re-colonize the Krakatau Archipelago within six years of the eruption, by actively swimming, passively rafting, or through the agencies of man, although the rate of re-colonization has slowed markedly since the 1930s (Rawlinson et al. 1992. *In* Thornton [ed.], Krakatau—A Century of Change, pp. 225–231. GeoJournal 28[2]:81–302). To date, seven species of reptiles have re-colonized the Krakatau Archipelago from source populations in southern Sumatra and western Java, and from other islands in the Sunda Strait, Sebesi, and Paniatan (Thornton 1996, *op. cit.*; Thornton et al. 2002. Biol. J. Linn. Soc. 77[3]:275–317). Continued eruptions of Anak Krakatau make re-establishment of the flora and fauna a punctuated process.

Gehyra mutilata is a widely distributed species, found throughout the entire Indonesian archipelago, including Sumatra and Java (de Rooji 1915. The Reptiles of the Indo-Australian Archipelago Vol. I. Lacertilia, Chelonia, Emydosauria. E. J. Brill, Leiden. xiv + 382 pp.). It is also a highly successful colonizer of islands and continents outside its natural range (Lever 2003. Naturalized Reptiles and Amphibians of the World. Oxford Univ. Press, Oxford. xx + 318 pp.). Future biological surveys of Krakatau Islands should search the eastern forests of Panjang to confirm that this species has established a permanent population.

We thank YAP Films and Animal Planet for funding and support of the project "Return of the Reptiles" (OBA2) and wish to acknowledge the pioneering Krakatau fieldwork of SC's mentor, Prof. Ian W. B. Thornton, who passed away in 2002.

HEMIDACTYLUS FRENATUS (Common House Gecko). MÉXICO: CHIAPAS: Municipality of Ocosingo: Frontera Corozal, Museo Regional de Frontera (16°49'16.6"N, 90°53'14.1"W), 101 m elev. 1 May 2004. Ricardo Paredes-León. Colección Nacional de Anfibios y Reptiles, Instituto de Biología, UNAM (CNAR-IBH 15663–65). Verified by Elisa Cabrera-Guzmán and Edmundo Pérez-Ramos. First record for the Lacandona region, extending its known range 140 km NW of Palenque, Chiapas (Lee 1996. The Amphibians and Reptiles of the Yucatán Peninsula. Comstock Publ. Assoc., Cornell Univ. Press, Ithaca, New York. 500 pp.). The specimens were collected at night on walls of the museum.

Submitted by **RICARDO PAREDES-LEÓN**, Colección Nacional de Ácaros, Instituto de Biología, UNAM, Ciudad Universitaria, México, D.F. 04510 (e-mail: skarabajo8@yahoo.com.mx); and **VÍCTOR-HUGO REYNOSO**, Colección Nacional de Anfibios y Reptiles, Instituto de Biología, UNAM, Ciudad Universitaria, México, D.F. 04510 (e-mail: vreynoso@ibunam.ibiologia.unam.mx).

NOROPS* (= *ANOLIS*) *SAGREI (Brown Anole). USA: SOUTH CAROLINA: ORANGEBURG CO.: Rest area on westbound I-26 at mile marker 152, ca. 3 km NW of the I-26/U.S. Rt. 301 jct. (33°28.849'N, 83°45.469'W). 07 June 2005. Florida State Museum of Natural History (UF 146016). Single adult male collected from landscaping vegetation adjacent to the main rest area building; one additional adult male observed on the building wall during an approx. 30 min. search of the grounds. COLLETON CO.: Rest area on northbound I-95 at mile marker 47, ca. 8 km NE of I-95/U.S. Rt. 21 jct. (32°48.164'N, 80°46.203'W). 30 June 2005. UF 146018. Single adult female collected from landscaping vegetation, relatively distant from rest area facilities and main parking; no other individuals observed. JASPER CO.: Welcome Center on northbound I-95, ca. 7 km NE of the Georgia-South Carolina border (32°15.962'N, 81°05.186'W). 30 June 2005. UF 146017. Single adult male collected from rocks bordering a water retention pond. Several adult males and females, approx. 10–15 total, were observed in various locations at this site in both May and June 2005. One small juvenile observed near the retention. All specimens verified by A. C. Echternacht. First records for South Carolina, extend range a maximum of 270 km N of Glynn County, Georgia record (Campbell 1996. Herpetol. Rev. 27:155–157). Jasper County lizards (ca. 125 km N of Glynn County record) might represent a recently established population. Dispersal to these rest areas is likely occurring via vehicular rafting (Campbell 1996, *op. cit.*; Godley et al. 1981. Herpetol. Rev. 12:84–86), though transport on ornamental vegetation is also a possibility at the Jasper and Colleton counties sites because cabbage palms from Florida nurseries were planted there in the mid-1990s and 2002, respectively, with possible replantings at later dates (South Carolina Department of Transportation, pers. comm.).

Submitted by **NATHAN W. TURNBOUGH**, Department of Ecology and Evolutionary Biology, University of Tennessee, 569 Dabney Hall, Knoxville, Tennessee 37996-4503, USA.

NOROPS SAGREI (Brown Anole). USA: TEXAS: HIDALGO CO.: City of La Joya, south shore of Walker Lake. 24 September 2005. Arianna McCoid. Texas Natural History Collection (TNHC) 64388. First specimen for this county. The species was listed as occurring in Hidalgo Co. (Dixon 2000. Amphibians and Reptiles of Texas. 2nd Ed. Texas A&M Univ. Press, 421 pp.) but apparently there is no corroborating specimen (*fide* J. Dixon, pers. comm.). The adult male specimen (53.4 mm SVL) was collected on the property of Mark and Rachel Medina; these homeowners had seen hatchlings of this species on their property this past summer. During the preceding two years the property had been landscaped with plants shipped directly from Florida and from local nurseries. BRAZORIA CO.: City of Alvin, 316 Windsor Square. 14 March 2006. M. J. McCoid. TNHC 64389. First specimen for this county (*op. cit.*). The adult male specimen (54.1 mm SVL) was collected at 1000 h. Several days prior to collection, a group of plants had been purchased from a Brazoria County nursery. Specimen identifications verified by Travis LaDuc.

Submitted by **MICHAEL JAMES McCOID**, Department of Pathology, University of Texas Medical Branch, 301 University Blvd., Galveston, Texas 77555-0609, USA; e-mail: mjmccoid@utmb.edu.

PODARCIS ERHARDII (Erhard's Wall Lizard). GREECE: ATTICA: Mount Parnitha (23°47'50"E, 38°10'02"N; 1160 m elev.). 17 October 2005. P. Pafilis. Natural History Museum of Crete (NHMC 80.3.51.1705–08, two males and two females). Verified by E. D. Valakos. The range includes diverse areas of mainland

and insular Greece. Believed to occur in Attica Prefecture (Wetstein 1953. Herpetologia Aegea, Sitzungsber. Osterr. Akad. Wiss. Math.-Naturwiss. K1., Wien 162[9–10]:42), no recent report of its presence exists. The finding represents the southernmost record of the species in mainland distribution, 40 km from Athens.

Submitted by **PANAYOTIS PAFILIS** and **CHRISA SIMOU**, Section of Animal Physiology, Department of Biology, University of Athens, 157–84, Panepistimiopolis, Ilisia, Athens, Greece (e-mail: ppafil@biol.uoa.gr).

TARENTOLA MAURITANICA. ARGENTINA: TUCUMÁN: San Miguel de Tucumán (26°49'50"S, 65°12'14"W). 26 February 2006. G. Ábalos. Herpetological collection Fundación Miguel Lillo, Tucumán, Argentina (FML 16982–16983). Verified by R. Montero. North African species introduced accidentally in South America (Achával and Olmos 1997. Anfibios y Reptiles del Uruguay. Pers. Edition, Montevideo 128 pp.). Previously known from Buenos Aires province, Argentina, and Montevideo, Uruguay (Castello and Gil Rivas 1980. Medicina 40:673–677; Achával and Gudynas 1983. Bol. Soc. Zool. Uruguay 1:7–10). First vouchered province record (previously mentioned without explanation by Freiberg 1977. El Mundo de los Saurios. Ed. Albatros, Buenos Aires, 104 pp.), extends known distribution in Argentina ca. 1300 km NW from the closest previous record in Buenos Aires.

Submitted by **MARÍA P. CABRERA** (e-mail: mpaucab@yahoo.com) and **CECILIA GUERRA** (e-mail: ceeciliaa@hotmail.com), Instituto de Herpetología, Fundación Miguel Lillo, Miguel Lillo 251, 4000 Tucumán, Argentina.

SERPENTES

ELAPSOIDEA TRAPEI (Trape's Garter Snake). MAURITANIA: GUIDIMAKA REGION: Precise locality not known, probably in the vicinity of Selibabi (15°09'N, 12°11'W). Audan. Entered in Muséum national d'Histoire naturelle, Paris in 1912 (MNHN 1912.0–447). Verified by Gernot Vogel. First record for Mauritania. Extends range 300 km north from the closest known locality at Bandafassi in southeastern Senegal (Trape and Mané 2004. Bull. Soc. Herpetol. France 109:5–34). This specimen was previously confused with *Elapsoidea semiannula moebiusi* (Broadley 1998. Afr. J. Herpetol. 47:13–23). *Elapsoidea trapei* is a recently described species that was known only from Senegal (Mané 1999. Bull. Soc. Herpetol. France 91:13–18).

Submitted by **JEAN-FRANCOIS TRAPE**, Institut de Recherche pour le développement (IRD), Laboratoire de Paludologie et Zoologie médicale, B.P. 1386, Dakar, Sénégal (e-mail: Jean-Francois.Trape@ird.sn); and **IVAN INEICH**, Muséum National d'Histoire Naturelle, Département de Systématique et Evolution, USM 602 (Reptiles–Taxonomie et Collections) CP 30, 25 rue Cuvier, 75231 Paris Cedex 05, France.

GYALOPION CANUM (Chihuahuan Hook-nosed Snake). MÉXICO: SONORA: Municipio de Yécora, 11.9 km (by Mex. Hwy 16) W Yécora (jct.) (28°21'45.2"N, 109°00'47.9"W), 1821 m elev. 6 August 2004. E. Enderson, K. Bonine, and R. Bezy. UAZ 56041-PSV. Verified by L. M. Hardy. This is the first record from the western slope of the Sierra Madre Occidental and extends the range 225 km SW from Colónia Juárez, Chihuahua, and 340 km S from Cananea, Sonora (Hardy 1975. J. Herpetol. 9:107–132; Tanner 1985. Great Basin Nat. 45:615–676). The snake was found DOR at 2205 h.

Submitted by **ERIK F. ENDERSON**, 2627 South Jaguar Road, Tucson, Arizona 85730, USA; **KEVIN E. BONINE**, Department of Ecology and Evolutionary Biology and School of Natural Resources, University of Arizona, Tucson, Arizona 85721, USA; and **ROBERT L. LIOPHOLIDOPHIS SEXLINEATUS (NCN). MADAGASCAR: ANTANANARIVO PROVINCE: Ankaratra Massif (19°20.532'S, 47°14.634'E; 2498 m elev.). 16 February 2006. Ylenia Chiari. Zoologische Staatssammlung München, Germany, ZCMV 2559. Another individual was collected nearby, by Miguel Vences, ZCMV 2561. The highest elevation recorded for this species and for any colubrid snake in Madagascar was 2110 m (Vences et al. 2002. Ital. J. Zool. 69:263–281). Specimens were identified on the basis of coloration and scale counts (Cadle 1996. Bull. Mus. Comp. Zool. 154:369–464): 17 dorsal, 150 ventral, 123 subcaudal, anal and all subcaudal scales but one divided for ZCMV 2559 and 17 dorsal, 136 ventral, 76 subcaudal, anal and all but three subcaudal scales divided for ZCMV 2561. Individuals observed during a sunny and warm day on the side of a rocky mountain path, one in the act of swallowing a frog (*Boophis microtympanum*). On the path nearby another individual of the same species was observed. It had been killed, probably by local people.

Submitted by **YLENIA CHIARI**, Zoological Museum of Amsterdam, Mauritskade 61, 1092 AD Amsterdam, The Netherlands (e-mail: yle@yleniachiari.it); **DINA MALALA RAVELONKASINA**, Départment de Biologie Animale, Faculté des Sciences, BP 906, Université d'Antananarivo, Antananarivo 101, Madagascar; and **EDWIGE FALIARISOA**, Départment de Biologie Animale, Faculté des Sciences, BP 906, Université d'Antananarivo, Antananarivo 101, Madagascar (e-mail: faliarisoaedwige@yahoo.fr).

NERODIA FASCIATA PICTIVENTRIS (Florida Watersnake). USA: CALIFORNIA: Los Angeles Co.: Harbor City: Kenneth Malloy Memorial Park: Machado Lake (aka Harbor Park Lake), along south lake margin at fishing dock 0.29 km (0.18 mi) NE of intersection of Vermont Ave and W. Anaheim St. A single dark-colored specimen (550 mm SVL). 3 April 2006. Collected by B. W. Trevett. LACM 161154 Verified by Jeffrey Seigel and Jeff Boundy. Allocation to ssp. *N. f. pictiventris* based on features of coloration and pattern. New state record for this subspecies. BWT photographed additional individuals and observed juveniles at same location. The presence of juveniles suggests that local reproduction is occurring at the site. Other records of *N. fasciata* in California include a reproducing population of *N. f. fasciata* in Sacramento Co. reported by Balfour and Stitt (2002. Herpetol. Rev. 33:150). Bury and Luckenbach (1976. Biol. Conserv. 10:1–14), give an account of a single individual of *Natrix* [=*Nerodia*] *fasciata* which they referred to as a "banded watersnake" and which was reportedly collected from a pond in "west Los Angeles" by a H. Campbell. The name "banded watersnake" is generally associated with *N. f. fasciata,* however, the true identity of the Campbell specimen has not been verified to our knowledge. Perhaps by coincidence, LACM has a specimen of *N. sipedon* with dark cross bands that was collected from El Dorado Park, Los Angeles Co., and dated September 1978 (LACM 109564). The LACM data sheet does not specify the city name for the *N. sipedon* specimen, but it is likely to be Long Beach, which has an El Dorado Park that contains a pond (and is located in west Los Angeles Co). Specimen LACM 109564 might therefore be the "banded watersnake" referred to by Bury and Luckenbach.

Submitted by **MICHAEL M. THAMNODYNASTES SERTANEJO. BRAZIL: MINAS GERAIS: Municipality of Jaíba (15°12'S, 43°42'W). 09 March 1995. G. A. Cotta. Fundação Ezequiel Dias, Belo Horizonte, Minas Gerais, Brazil (FUNED 907). 22 July 1998. R. N. Feio and J. L. Pontes. Museu Nacional, Rio de Janeiro, Rio de Janeiro, Brazil (MNRJ 8048). Municipality of Jaíba, Mocambinho (14°48'S, 43°55'S). 20 August 1992. M. C. Brito-Pereira. Museu Nacional (MNRJ 8583). BAHIA: Municipality of Paulo Afonso, Usina Hidrelétrica Itaparica (09°21'S, 38°14'W). 30 January 1987. U. Simon. (FUNED 244). The species was previously known only from Municipality of Jaguarari, state of Bahia, and the Municipality of Exu, state of Pernambuco, Brazil (Bailey et al. 2005. Phyllomedusa 4[2]:83–101). First record from the state of Minas Gerais and (Jaíba), ca. 732 km southwest from the closest previous record (Bahia, Municipality of Jaguarari, Mine of Caraíba, 39°52'S, 09°51'W; Bailey et al., *op. cit.*), also the eastern limit of its distribution (Paulo Afonso), ca. 190 km east from the closest record (Jaguarari). All these localities are located in "Caatinga" biome.

Range Extensions for Reptiles and Amphibians along the Northern Versant of Papua New Guinea

FRED KRAUS
and
ALLEN ALLISON
Bishop Museum, 1525 Bernice Street
Honolulu, Hawaii 96813, USA
e-mail: fkraus@hawaii.edu

The herpetofauna of New Guinea remains relatively poorly known, with 103 new species described since 2000, scores new species remaining to be described, and large parts of the island poorly surveyed. For those species already described, geographic ranges are poorly understood; for example, approximately 40% of frog species are still known only from their type localities. We have recently provided a significant number of new range extensions for the southeasternmost tip of New Guinea and adjacent islands (Kraus and Allison 2004; Kraus and Shea 2005), and Günther (2003a) has done the same for the western end of New Guinea. Here we present a similar list for the northern versant of Papua New Guinea. This portion of the island, north of the Central Dividing Range, consists of a series of independent mountain ranges (and their intervening depositional basins) that are the remnants of an arc of former islands sutured onto the northern margin of New Guinea over the past ten million years (Pigram and Davies 1987).

Below we provide range extensions based primarily on expeditions we conducted to the Bewani, Hunstein, and Torricelli mountains, but we supplement these with a few additional extensions from Mt. Shungol to the east of the Central Dividing Range and just south of the most recently sutured terrane (Finisterre) comprising the Huon Peninsula. For the sake of completeness, we also supplement our accounts for one species of *Callulops* and three species of *Litoria* with additional data from outside the northern versant of the island. All specimens are deposited in the Bernice P. Bishop Museum (BPBM). All coordinates use the AGD 66 datum.

Anura

Albericus brunhildae. EAST SEPIK PROV.: Hunstein Mts.: 1.3 km S & 2.3 km E Mt. Hunstein summit, 4.5226°S, 142.6748°E, 1000 m asl. 25 September–5 October 1989. A. Allison. BPBM 20884–902; WEST SEPIK PROV.: Bewani Mts.: Agpo Creek, 8.5 km N & 13 km E Utai, 3.312°S, 141.7°E, 1100 m asl. 28 September 1986. A. Allison. BPBM 20991–93; summit Mt. Menawa, 10.5 km N & 15.7 km E of Utai, 3.295°S, 141.723°E, 1920 m asl. 19–20 October 1986. A. Allison. BPBM 20994–98. First provincial records; previously known only from Adelbert Mts., 300 km to the E and 460 km to the SSE, respectively (Menzies 1999).

Asterophrys leucopus. EAST SEPIK PROV.: Hunstein Mts.: 1.3 km. S & 2.3 km E Mt. Hunstein summit, 4.5226°S, 142.6748°E, 1000 m asl. 30 September–2 October 1989. A. Allison. BPBM 16585–88; WEST SEPIK PROV.: Bewani Mts.: Agpo Creek, 8.5 km N & 13 km E Utai, 3.312°S, 141.7°E, 950 m asl. 26–28 Sep-

tember 1986. A. Allison. BPBM 14369, 14371–72; Agpo Creek, 8.5 km N & 14 km E of Utai, 3.309°S, 141.709°E, 1200 m asl. 22–23 October 1986. A. Allison. BPBM 14370, 14373. Range extensions of 100 km to the ENE and 175 km to the N, respectively, of Mt. Stolle (Richards et al. 1994).

Austrochaperina adamantina. WEST SEPIK PROV.: Bewani Mts.: vicinity Trefas Village, 5.9 km N & 7.3 km E Utai, 3.333°S, 141.651°E, 340 m asl. 23 October 1986. A. Allison. BPBM 14234. Previously known only from Mt. Nibo, Torricelli Mts., 70 km to the E (Zweifel 2000).

Austrochaperina aquilonia. WEST SEPIK PROV.: Bewani Mts.: Agpo Creek, 8.5 km N & 13 km E of Utai, 3.312°S, 141.7°E, 950 m asl. 28–29 September 1986. A. Allison. BPBM 14235–38; Agpo Creek, 8.5 km N & 14 km E of Utai, 3.309°S, 141.709°E, 1200 m asl. 22 October 1986. A. Allison. BPBM 14239. Previously known only from NE of Lumi, Torricelli Mts., ~70 km to the E (Zweifel 2000).

Austrochaperina basipalmata. WEST SEPIK PROV.: Bewani Mts.: Agpo Creek, 8.5 km N & 13 km E of Utai, 3.312°S, 141.7°E, 940–950 m asl. 24–27 September 1986. A. Allison. BPBM 14212, 14241–43; Agpo Creek, 8.5 km N & 14 km E of Utai, 3.309°S, 141.709°E, 1200 m asl. 6 October 1986. A. Engilis, Jr. BPBM 14213. Fills in 150 km range gap between localities in eastern Papua Prov., Indonesia and Torricelli Mts., PNG (Zweifel 2000).

Austrochaperina blumi. EAST SEPIK PROV.: Hunstein Mts.: 1.3 km. S & 2.3 km E Mt. Hunstein summit, 4.5226°S, 142.6748°E, 1000 m asl. 30 September–5 October 1989. A. Allison. BPBM 16581–84; WEST SEPIK PROV.: Bewani Mts.: Agpo Creek, 8.5 km N & 13 km E of Utai, 3.312°S, 141.7°E, 950 m asl. 20–27 September 1986. A. Allison. BPBM 14240, 14244–45; vicinity Trefas Village, 5.9 km N & 7.3 km E Utai, 3.333°S, 141.651°E, 340 m asl. 23 October 1986. A. Allison. BPBM 14246; Torricelli Mts.: 3.2 km SSE Mt. Sapau summit, 3.3933°S, 142.5283°E, 550 m asl. 20–26 May 2005. F. Kraus. BPBM 22653–58, 22661–63. Range extensions of 140 km to the NE, 220 km to the N, and 220 km to the NNE, respectively, of nearest locality near Telefomin (Zweifel 2000).

Austrochaperina parkeri. MOROBE PROV.: Along Dunch River 5.6 km NW summit Mt. Shungol, 6.8162°S, 146.6915°E, 750 m asl. 16–24 October 2003. F. Kraus and native collectors. BPBM 18385–90. Previously known only from type locality 35 km to the NNE on other side of Markham River (Zweifel 2000).

Austrochaperina septentrionalis. WEST SEPIK PROV.: Torricelli Mts.: 1.6 km SSW Mt. Sapau summit, 3.3807°S, 142.5155°E, 1120 m asl. 27 May 2005. I. Haguna. BPBM 22668–69. Previously known only from Bewani Mts. ~130 km to W (Allison and Kraus 2003).

Callulops personata. MOROBE PROV.: Along Dunch River 5.6 km NW summit Mt. Shungol, 6.8162°S, 146.6915°E, 750 m asl. 23 October 2003. F. Kraus & native collectors. BPBM 18504; E slope Bowutu Mts., 7.2960°S, 147.0929°E, 520–530 m asl. 29 March–1 April 2005. J. Anamiato. BPBM 23739–23740. First provincial records and range extensions of 520 km and 580 km to the SSE of Maprik (Zweifel 1972a).

Choerophryne longirostris. WEST SEPIK PROV.: Torricelli Mts.: 1.2 km S Mt. Sapau summit, 3.3773°S, 142.5180°E, 1120–1320 m asl. 27 May 2005. F. Kraus. BPBM 22672–76. Range extension of 120 km to the E from only known localities in Bewani Mts. (Kraus and Allison 2001).

Cophixalus balbus. EAST SEPIK PROV.: Hunstein Mts.: 1.3 km S & 2.3 km E Mt. Hunstein summit, 4.5226°S, 142.6748°E, 1000 m asl. 26 September – 2 October 1989. A. Allison. BPBM 16590–96; WEST SEPIK PROV.: Bewani Mts.: vicinity Trefas Village, 5.9 km N & 7.3 km E Utai, 3.333°S, 141.651°E, 320 m asl. 2 October 1986. A. Allison. BPBM 14382; Koske Creek, 4 km W Utai aerodrome, 3.393°S, 141.552°E, 210 m asl. 29 October 1986. A. Allison. BPBM 14383; Agpo Creek, 8.5 km N & 14 km E of Utai, 3.309°S, 141.709°E, 1200 m asl. 22 October 1986. A. Allison. BPBM 14384; 2 km W Utai Aerodrome, 3.391°S, 141.564°E, 210 m asl. 28 October 1986. A. Allison. BPBM 14392; Torricelli Mts.: 3.2 km SSE Mt. Sapau summit, 3.3933°S, 142.5283°E, 550 m asl. 20–25 May 2005. F. Kraus. BPBM 22690–701, 22706. First country records and range extensions of 760 km, 600 km, and 690 km, respectively, to the SSE of Yapen Island (Günther 2003b).

Lechriodus melanopyga. WEST SEPIK PROV.: Bewani Mts.: 2 km W Utai Aerodrome, 3.391°S, 141.564°E, 210 m asl. 28–30 October 1986. A. Allison. BPBM 14431–32; Utai Aerodrome, 3.389°S, 141.585°E, 210 m asl. 12 September 1986. A. Allison. BPBM 14433. Fills in 550 km range gap between Jayapura and Adelbert Mts. (Zweifel 1972b).

Lechriodus platyceps. WEST SEPIK PROV.: Bewani Mts.: Agpo Creek, 8.5 km N & 14 km E of Utai, 3.309°S, 141.709°E, 1200 m asl. 15–17 October 1986. A. Allison & A. Engilis, Jr. & A. Yaiko. BPBM 14434, 14438–39; Mt. Menawa, 9.4 km N & 14.1 km E of Utai, 3.302°S, 141.712°E, 1500 m asl. 7–16 October 1986. A. Engilis, Jr. & A. Yaiko. BPBM 14435, 14442–43; Mt. Menawa, 9.6 km N &14.2 km E of Utai, 3.301°S, 141.713°E, 1600 m asl. 15–21 October 1986. A. Allison, A. Engilis, Jr. & A. Yaiko. BPBM 14436, 14440; Mt. Menawa, 9.8 km N & 14.4 km E of Utai, 3.3°S, 141.714°E, 1700 m asl. 18 October 1986. A. Allison. BPBM 14437. First records for country and range extension of ~320 km to the E of Idenburg River (Zweifel 1972b).

Limnonectes grunniens. WEST SEPIK PROV.: Bewani Mts.: Koske Creek, 4 km W Utai aerodrome, 3.393°S, 141.552°E, 220 m asl. 30 October 1986. Native collector. BPBM 13406. First report from N of the Sepik River and range extension of ~90 km from nearest locality to the S (Menzies 1987).

Liophryne schlaginhaufeni. WEST SEPIK PROV.: Bewani Mts.: Agpo Creek, 8.5 km N & 14 km E of Utai, 3.309°S, 141.709°E, 1200 m asl. 1–22 October 1986. A. Allison, A. Engilis, Jr. & A. Yaiko. BPBM 14444, 14446, 14448, 14451, 14453, 16563; Agpo Creek, 8.5 km N & 13 km E of Utai, 3.312°S, 141.7°E, 950 m asl. 26–30 September 1986. A. Allison. BPBM 14445, 14447, 14449–50, 14454. Range extension of 80 km W of nearest locality at Mt. Nibo, Torricelli Mts. (Zweifel 2000).

Litoria exophthalmia. EAST SEPIK PROV.: Hunstein Mts.: Hunstein River, 8.7 km N & 9.8 km E summit Mt. Hunstein, 4.4321°S, 142.7414°E, 75 m asl. 16–17 September 1989. A. Allison. BPBM 16623–35; GULF PROV.: Kakoro, 7.846°S, 146.523°E, 70 m asl. 20 July 1982. A. Allison. BPBM 21533–38. New provincial records and range extensions of ~370 km to the NW and

~200 km to the SE, respectively, of only previously reported locality at Crater Mt., Chimbu Prov. (Tyler et al. 1986).

Litoria genimaculata. WEST SEPIK PROV.: Torricelli Mts.: 3.2 km SSE Mt. Sapau summit, 3.3933°S, 142.5283°E, 550 m asl. 18–24 May 2005. F. Kraus. BPBM 23223–42. First record for any north coast range (Menzies 1975; Tyler 1968).

Litoria iris. EAST SEPIK PROV.: Hunstein Mts.: 1.3 km. S & 2.3 km E Mt. Hunstein summit, 4.5226°S, 142.6748°E, 1000 m asl. 25 September–2 October 1989. A. Allison. BPBM 23505–06, 23508–11. First record for province and N of Central Dividing Range (Menzies 1993).

Litoria leucova. EAST SEPIK PROV.: Hunstein Mts.: 1.3 km S & 2.3 km E Mt. Hunstein summit, 4.5226°S, 142.6748°E, 1000 m asl. 2 October 1989. A. Allison. BPBM 23515–16. First provincial record and range extension 100 km NE of nearest locality in West Sepik Prov. (Johnston and Richards 1994).

Litoria micromembrana. EAST SEPIK PROV.: Hunstein Mts.: 1.3 km S & 2.3 km E Mt. Hunstein summit, 4.5226°S, 142.6748°E, 1000 m asl. 26 September–2 October 1989. A. Allison. BPBM 23507, 23512; CENTRAL PROV.: W flank Mt. Obree, 9.4606°S, 148.0282°E, 1800–2040 m asl. 4–7 February 2004. F. Kraus. BPBM 19250, 19378–80, 19383; 9.4601°S, 148.0304°E, 1800–2040 m asl. 4–7 February 2004. F. Kraus. BPBM 19252–53, 19381–82. First records for each province and each mountain range; East Sepik Province record extends range 130 km NE of known population at Telefomin; Central Province record extends range 420 km SE of record at Okapa (Tyler 1968).

Litoria modica. CENTRAL PROV.: 1.2 km E Woitape, 8.4568°S, 147.2620°E, 1620 m asl. 2 October 2003. F. Kraus. BPBM 18496; EAST SEPIK PROV.: Hunstein Mts.: 1.3 km S & 2.3 km E Mt. Hunstein summit, 4.5226°S, 142.6748°E, 1000 m asl. 30 September–2 October 1989. A. Allison. BPBM 23486–503; MOROBE PROV.: Along Dunch River 5.6 km NW summit Mt. Shungol, 6.8162°S, 146.6915°E, 750 m asl. 18 October 2003. F. Kraus. BPBM 18497–500; 5.35 km NW summit Mt. Shungol, 6.8188°S, 146.6933°E, 780 m asl. 21 October 2003. F. Kraus. BPBM 18501–02; WEST SEPIK PROV.: Bewani Mts.: Agpo Creek, 8.5 km N & 13 km E of Utai, 3.312°S, 141.7°E, 950 m asl. 20–27 September 1986. A. Allison. BPBM 14757–64, 14766–69; Agpo Creek, 8.5 km N &14 km E of Utai, 3.309°S, 141.709°E, 1135 m asl. 27 September 1986. A. Allison. BPBM 14765; Torricelli Mts.: 1.6 km SSW Mt. Sapau summit, 3.3807°S, 142.5155°E. 1050 m asl. 25 May 2005. F. Kraus. BPBM 23245. First records for each province and each mountain range (Tyler 1968; Global Amphibian Assessment 2006); Central Prov. record fills in a ~520 km gap between Central Dividing Range and southern end of Owen Stanley Mts. (Kraus and Allison 2004).

Litoria wollastoni. WEST SEPIK PROV.: Torricelli Mts.: 3.2 km SSE Mt. Sapau summit, 3.3933°S, 142.5283°E, 550 m asl. 20–24 May 2005. F. Kraus. BPBM 23222, 23246–48; 1.6 km SSW Mt. Sapau summit, 3.3807°S, 142.5155°E. 1050 m asl. 25–26 May 2005. Native collectors. BPBM 23249–50. First records for province and N of Central Dividing Range (Menzies and Zweifel 1974).

Nyctimystes pulchra. EAST SEPIK PROV.: Hunstein Mts.: 1.3 km S & 2.3 km E Mt. Hunstein summit, 4.5226°S, 142.6748°E, 1000 m asl. 5 October 1989. A. Allison. BPBM 17368; WEST SEPIK PROV.: Bewani Mts.: Agpo Creek, 8.5 km N & 13 km E of Utai, 3.312°S, 141.7°E, 950 m asl. 27 September 1986. A. Allison. BPBM 17369–70; vicinity Trefas Village, 5.9 km N & 7.3 km E Utai, 3.333°S, 141.651°E, 340 m asl. 24–25 October 1986. A. Allison. BPBM 17371–72. First records for each mountain range and first record for East Sepik Province; previously only reported from Torricelli Mts. and Huon Peninsula among the north coast ranges (Menzies 1975; Zweifel 1958).

Oreophryne biroi. WEST SEPIK PROV.: Bewani Mts.: vicinity Trefas Village, 5.9 km N & 7.3 km E Utai, 3.333°S, 141.651°E, 320 m asl. 2 October 1986. A. Allison. BPBM 14509–11. Fills in 200 km gap in range between Cyclops Mts. and Torricelli Mts. (Zweifel et al. 2003).

Oreophryne parkeri. WEST SEPIK PROV.: Bewani Mts.: vicinity Trefas Village, 5.9 km N & 7.3 km E Utai, 3.333°S, 141.651°E, 340 m asl. 24 October 1986. A. Allison. BPBM 23475–76; Torricelli Mts.: Parkop, 6.5 km S Mt. Sapau summit, 3.4246°S, 142.5187°E, 416 m asl. 14–15 May 2005. F. Kraus. BPBM 22781–84; 3.2 km SSE Mt. Sapau summit, 3.3933°S, 142.5283°E, 550 m asl. 18 May 2005. F. Kraus. BPBM 22785. Records fill in ~300 km gap between only two prior localities at Sentani, Papua Prov., and Matapau, West Sepik Prov. (Zweifel et al. 2003).

Platymantis cheesmanae. WEST SEPIK PROV.: Bewani Mts.: 2 km W Utai Aerodrome, 3.391°S, 141.564°E, 210 m asl. 28 October 1986. A. Allison. BPBM 12216–18. First record for country and range extension of 180 km E from only known locality in Cyclops Mts. (Zweifel 1969).

Rana jimiensis. WEST SEPIK PROV.: Torricelli Mts.: Parkop, 6.5 km S Mt. Sapau summit, 3.4246°S, 142.5187°E, 416 m asl. 14 May 2005. Native collector. BPBM 22831; 3.2 km SSE Mt. Sapau summit, 3.3933°S, 142.5283°E, 550 m asl. 18–28 May 2005. Native collectors. BPBM 22832–37, 22842; 1.6 km SSW Mt. Sapau summit, 3.3807°S, 142.5155°E. 1050 m asl. 25–26 May 2005. Native collectors. BPBM 22838–41. First records for north coast ranges and range extension of ~220 km NE of nearest reported locality near headwaters of Sepik River (Menzies 1987).

Rana volkerjane. WEST SEPIK PROV.: Bewani Mts.: Utai Aerodrome, 3.389°S, 141.585°E, 210 m asl. 12 September 1986. A. Allison. BPBM 13360; vicinity Trefas Village, 5.9 km N & 7.3 km E Utai, 3.333°S, 141.651°E, 320–340 m asl. 18 September – 24 October 1986. A. Allison. BPBM 13362–64, 13366, 13368–80, 13394–98, 13401; Menawa River, 8.4 km N & 11.4 km E of Utai, 3.312°S, 141.688°E, 560 m asl. 24 September 1986. A. Allison. BPBM 13391; Koske Creek, 4 km W Utai aerodrome, 3.393°S, 141.552°E, 220 m asl. 29 October 1986. A. Allison. BPBM 13404; Torricelli Mts.: Parkop, 6.5 km S Mt. Sapau summit, 3.4246°S, 142.5187°E, 416 m asl. 12–16 May 2005. Native collectors. BPBM 22810–15; 3.2 km SSE Mt. Sapau summit, 3.3933°S, 142.5283°E, 550 m asl. 18–23 May 2005. Native collectors. BPBM 22816–27; 1.6 km SSW Mt. Sapau summit, 3.3807°S, 142.5155°E. 1050 m asl. 25–26 May 2005. Native collector. BPBM 22828. First records for country and range extensions of 780 and 860 km, respectively, to the E of Wondiwoi Mts. (Günther 2003c).

Xenobatrachus tumulus. WEST SEPIK PROV.: Bewani Mts.: 2

km W Utai Aerodrome, 3.391ºS, 141.564ºE, 210 m asl. 28–29 October 1986. A. Allison. BPBM 14065–66; Torricelli Mts.: 3.2 km SSE Mt. Sapau summit, 3.3933ºS, 142.5283ºE, 550 m asl. 23 May 2005. Native collector. BPBM 22795. First records for province and range extensions of 450 km and 370 km, respectively, to the WNW from only known locality in Adelbert Mts. (Blum and Menzies 1988).

Xenorhina arboricola. WEST SEPIK PROV.: Torricelli Mts.: 1.6 km SSW Mt. Sapau summit, 3.3807ºS, 142.5155ºE, 1120 m asl. 27 May 2005. F. Kraus. BPBM 22796–97. Previously known only from Bewani Mts. and Hunstein Mts. ~130 km to the W and ~125 km to the SSE, respectively (Allison and Kraus 2000).

Lacertilia

Cyrtodactylus sermowaiensis. EAST SEPIK PROV.: Hunstein Mts.: Hunstein River, 8.7 km N & 9.8 km E summit Mt. Hunstein, 4.4321ºS, 142.7414ºE, 75 m asl. 18 September 1989. A. Allison. BPBM 17322. First record S of Sepik River and range extension of ~70 km to the SW of nearest locality north of that river (Bauer and Henle 1994).

Emoia irianensis. WEST SEPIK PROV.: Bewani Mts.: Agpo Creek, 8.5 km N & 14 km E of Utai, 3.309ºS, 141.709ºE, 1200 m asl. 29 September 1986. A. Allison. BPBM 13542; summit Mt. Menawa, 10.5 km N & 15.7 km E of Utai, 3.295ºS, 141.723ºE, 1920 m asl. 19–21 October 1986. A. Allison. BPBM 13544–51, 23062–63. First records for country and range extension of ~580 km to the ENE of the Wissel Lakes area (Brown 1991).

Emoia kordoana. EAST SEPIK PROV.: Hunstein Mts.: Hunstein River, 4.9 km N & 6.3 km E summit Mt. Hunstein, 4.4665ºS, 142.7108ºE, 100 m asl. 29 September 1989. A. Allison. BPBM 13478. First provincial record (Brown 1991).

Emoia oribata. EAST SEPIK PROV.: Hunstein Mts.: 0.7 km S & 6.3 km E summit Mt. Hunstein, 4.5181ºS, 142.7108ºE, 900 m asl. 24 September 1989. A. Allison. BPBM 13476; 1.3 km S & 2.3 km E Mt. Hunstein summit, 4.5226ºS, 142.6748ºE, 1000 m asl. 5 October 1989. A. Allison. BPBM 13477; WEST SEPIK PROV.: Bewani Mts.: vicinity Trefas Village, 5.9 km N & 7.3 km E Utai, 3.333ºS, 141.651ºE, 340 m asl. 23 October 1986. A. Allison. BPBM 13555. Hunstein records are first provincial records [Brown (1991) erroneously lists the Frieda River specimens BPBM 10590–93 as East Sepik Prov.; in actuality, they are just S of the border in West Sepik Prov.] and range extension of 100 km to the E of Frieda River; Bewani record is a range extension of 130 km to the N of Frieda River locality.

Emoia popei. EAST SEPIK PROV.: Hunstein Mts.: Hunstein River, 4.9 km N & 6.3 km E summit Mt. Hunstein, 4.4665ºS, 142.7108ºE, 100 m asl. 23 September 1989. A. Allison. BPBM 13471. Range extension of 180 km to the SSW from prior westernmost record at Marienberg (Brown 1991).

Gehyra oceanica. WEST SEPIK PROV.: Torricelli Mts.: Parkop, 6.5 km S Mt. Sapau summit, 3.4246ºS, 142.5187ºE, 416 m asl. 14 May 2005. Native collector. BPBM 23348; Sibilanga, 3.4488ºS, 142.4982ºE, 720 m asl. 31 May 2005. Native collector. BPBM 23349. Fills in ~670 km range gap between Jayapura and Madang (Bauer and Henle 1994).

Lipinia cheesmanae. EAST SEPIK PROV.: Hunstein Mts.: 1.3 km S & 2.3 km E Mt. Hunstein summit, 4.5226ºS, 142.6748°E, 1000 m asl. 26 September 1989. A. Allison. BPBM 12660. First record for country and range extension of 325 km E from the nearest known locality in Cyclops Mts. (Günther 2000).

Varanus doreanus. EAST SEPIK PROV.: Hunstein Mts.: 1.3 km S & 2.3 km E Mt. Hunstein summit, 4.5226ºS, 142.6748°E, 1000 m asl. 30 September 1989. A. Allison. BPBM 21464. First record for province and fills in ~1100 km range gap between Biak Island, Papua Prov., and Madang, Madang Prov. (Böhme et al. 1994).

Varanus jobiensis. EAST SEPIK PROV.: Hunstein Mts.: Hunstein River, 4.9 km N & 6.3 km E summit Mt. Hunstein, 4.4665ºS, 142.7108ºE, 100 m asl. 21–23 September 1989. A. Allison. BPBM 21462–63; WEST SEPIK PROV.: Bewani Mts.: vicinity Utai, 3.389ºS, 141.585ºE, 210 m asl. 14 September 1986. A. Allison. BPBM 23157. First records for each mountain range, first record for West Sepik Province, and each fills in ~800 km range gap between Marienburg, East Sepik Prov., and Yapen Island, Papua Prov. (Böhme et al. 1994).

Serpentes

Tropidonophis mcdowelli. EAST SEPIK PROV.: Hunstein Mts.: 1.3 km S & 2.3 km E Mt. Hunstein summit, 4.5226ºS, 142.6748°E, 1000 m asl. 5 October 1989. A. Allison. BPBM 18218. First record for province and range extension of 120 km to the SE of Mt. Nibo, Torricelli Mts. (Malnate and Underwood 1988).

Ramphotyphlops erycinus. WEST SEPIK PROV.: Torricelli Mts.: 3.2 km SSE Mt. Sapau summit, 3.3933ºS, 142.5283ºE, 550 m asl. 24–28 May 2005. F. Kraus. BPBM 23457–58. First record for province and fills in 730 km range gap between Toem, Papua Prov., and Awar, Madang Prov. (McDowell 1974).

There is a rich, centuries-old tradition of natural history books by gentleman naturalists; and tomes on turtles and tortoises are particularly noteworthy in this genre. The volume under review, an extension of this custom, is attractively presented, with glossy paper, tight binding, and 188 figures, most of which are in color. Its eight chapters are: Introduction; Identification of the Indian Ocean giant tortoises and theories of their evolution; The morphology of giant tortoises; Taxonomy; Ecology; The discovery of Indian Ocean giant tortoises and their history; Conservation; and Bibliography. An enormous amount of historic, factual, theoretical, hypothetical, and speculative information is summarized in the book, presented together with a wealth of old, difficult-to-find text and photos. There is a table of contents, but no list of tables or figures, or even a general index—usual components for any scholarly tome as large and complex as this. And this raises a fundamental question: what is the objective of this publication? Will serious students—seeking much-needed scholarly treatment of Indian Ocean giant tortoises, with organized, up-to-date summaries and syntheses—find that it meets their needs and expectations? Or, is its cache of color photos and attractive presentation designed for an active hobbyist market, less concerned about seemingly pedantic details of the scientific debates, hypothesis testing, and the International Code of Zoological Nomenclature?

The book has an uneasy mix of styles, ranging from general, simplified stories of natural history to curt accounts of highly specialized analytical processes and terms—often with no explanation, background, or context for understanding the information presented or the issue under discussion. Numerous comments, claims, and arguments throughout the book raise basic concerns and distract from an easy read. Surely many of these contentious points of substance (not to mention the miscellaneous details of form including punctuation, grammar, redundancies, inconsisten-

cies, self-contradictions, incomplete citations and so on) could have been polished or mitigated had usual peer and editorial review processes been employed.[i] Only a sample of notable points is discussed herein.

The introduction sets the style for the volume; its three-and-a-half pages of text are accompanied by copious figures: in this case, ten, eight of which are in color. We are told that despite several in-depth works on the Galápagos tortoises, "their taxonomy remains highly confused" (p. 10). Yet, in treating the subject of the book, the Indian Ocean tortoises, the author simply states that there are two genera: "*Dipsochelys*" from the Madagascar to Seychelles, and *Cylindraspis* on the volcanic Mascarene islands. There is no mention in the introduction that the first name is promoted steadfastly by the author, despite its rejection in numerous peer-reviewed, scholarly studies by specialists knowledgeable of the taxonomic and nomenclatural issues (e.g., Crumly 1986; Pritchard 1986:532; Meylan and Auffenberg 1987:74; King and Burke 1989:70; Iverson 1992:249; Austin and Arnold 2001; Austin et al. 2002, 2003). These, and other, authors have argued, for decades, that the generic term *Aldabrachelys* is available and senior to "*Dipsochelys*," coined in 1982 by Roger Bour. Not only is "*Dipsochelys*" not widely used, especially in the scientific literature, but recently Bour has been co-author of peer-reviewed papers that employed the more usual *Aldabrachelys* (see Austin et al. 2002, 2003).

Near the end of the Introduction, the author states (p. 14) that "there are no external features which distinguish the three groups" [Galápagos, Mascarene, and Seychelles]—a claim with tremendous implications that is soon contradicted. Figures in the Introduction provide excellent images of heads of Aldabra, Mascarene, and Galápagos giant tortoises, clearly illustrating differences in head shape that many tortoise enthusiasts use to differentiate these three clades, and a distinguishing feature that has been well known for over a century (e.g., Gray 1872:3–4). In addition to several prominent personalities recognized by the author, other illustrations include a "phylogeny of recent tortoises" and a "world map of living and extinct giant tortoise distribution." It is remarkable that although several recent scientific studies directly applicable to questions of phylogeny are relatively easy to obtain (see below), the scheme proposed in this book is based on an unpublished thesis and one of three (which one is not identified) 2001 publications by the author that appeared in *Phelsuma*.[ii] The world map will disappoint tortoise aficionados who marvel at the gigantic size of living continental forms such as *Geochelone* [*Chelonoidis*] *denticulata* from northern South America (Pritchard 1986), *Geochelone* [*Centrochelys*] *sulcata* from northern Africa, and *Manouria emys* from Southeast Asia, not to mention scores of extinct gigantic forms (e.g., Auffenberg 1974) whose representation would have populated much of the apparently blank areas on the map. The closing of the Introduction states that "[i]n all cases the original literature has been tracked down to determine the real facts and separate them from the all too frequent myths that these animals seem to inspire." It is no mean feat to separate "real facts" from myths, especially when a writer is passionate about his topic.

Chapter Two, on identification and theories of evolution, begins with a candid appraisal of the problems: 18th and 19th century specimens without accurate localities; dubious original descriptions; confused type specimens, many described after having been transported from native lands; early diagnoses based on highly variable features and small sample sizes (commonly, just one specimen); and the less than careful use of taxonomic names. The summary of the intriguing early history of naming Indian Ocean tortoises is useful, and here the author explains some of the confusion and chaos in which the names of these chelonians are enmeshed. Curiously, he presents Schweigger's 1812 description for *T. gigantea* in French as if this were the original, and then gives an English translation. Schweigger (1812), as was common at that period, wrote in Latin (see also Duméril and Bibron 1834:416; Crumly 1986:238; Pritchard, 1986:522), but apparently Gerlach used Bour's (1984a:163) French translation, without explaining his source.

More importantly, a debatable logic is used in deciding which taxonomic names to reject and which to employ. The confusion regarding the generic name was mentioned above; the contention regarding the correct species appellation is more acute. A name that has been in regular usage for more than a century in hundreds of scientific publications about Aldabra tortoises—Schweiger's 1812 *Testudo gigantea* (Frazier 2006)—is rejected and replaced with Gray's 1831 *T. dussumieri*. But, this last name was clearly used by Gray (1831a:3, 1831b:9) only as a synonym to *T. indica*; and, hence, it is unavailable if one follows the International Code of Zoological Nomenclature (Art. 11.6; Frazier, *in prep.*). Moreover, another name, applied to a specimen of unknown origin, and with a transport history and final fate that reads like an adventure book, a name essentially forgotten for more than a century—*Testudo hololissa*—is recognized as a separate species. This is applied to specimens for which all available genetic information indicates that they are indistinguishable from the Aldabra tortoise (Palkovacs et al. 2002, 2003; Austin et al. 2003; Karanth et al. 2005; Noble, *in litt.* 10 August 2005).

Statements about ***results*** from studies of molecular genetics are generally consistent with the publications cited, but numerous matter-of-fact ***interpretations*** are subject to debate. The root of the dilemma lies with the author's conviction that since 1995 he has rediscovered at least two, near-extinct species of giant tortoises in the Seychelles, claims that have been made primarily in hobbyist and proprietary magazines (Gerlach and Canning 1995a,1995b, 1996:33, 1998a, 1998b:134; Gerlach 1997a:28, 1997b:71 ff., 1998a:31 ff., 1998b:4, 1999a:58, 1999b:9, 1999c:34, 1999d:496, 2001a:12, 2001b:127, 2002, 2003a:57, 2003b:8, 2005:938). These assertions have been substantiated by authoritative statements about proof of genetic differences between these so-called distinct species (Gerlach 1997a:28, 1997b:71 ff., 1998b:6, 2003a:59; Gerlach and Canning 1998b:134), allegations that were based on Les Noble's unpublished results of RAPDs research. However, these claims are inconsistent with what was found by the geneticist who did the work (Noble, *in litt.* 10 Aug. 2005, 24 Aug. 2005). Hence, it is refreshing that in his book Gerlach at last admits (p. 37) that "[r]ecent molecular analyses (Austin & Arnold 200 [sic.]; Austin et al. 2003; Palkovacs et al. 2002, 2003) have failed to locate any genetic differences between the living taxa or any genetic structuring of wild populations on Aldabra."

However, he goes on to contend (p. 37) that despite these recent, peer-reviewed publications that ***expressly*** investigated the question of specific differentiation "species differences are found in other molecular data." This bold claim is based on Cunningham's (2002) unpublished thesis which studied the cytochrome *b* gene (Cyt *b*) and the little-investigated nicotinamide adenine dinucle-

otide dehydrogenase subunit 4 gene (ND4). Her principal aim and methods were to "elucidate the inter-generic relationships among extant tortoises using two mitochondrial gene fragments"—***not*** to investigate species differences. She found no differences between individual Aldabra/Seychelles tortoises at the Cyt *b* site; and at the ND4 site the difference was "a maximum of 8bp [base pairs] in total and usually zero;" and it was unclear how to interpret this low level of differentiation, or indeed if it was due to artifacts (*in litt.* 3 August 2005). Hence, the author herself is not convinced that the molecular data alone support species differences in the six Aldabra/Seychelles tortoises that were sampled (*in litt.* 3 Aug. 2005, 7 Feb. 2006).

To explain the lack of genetic differences Gerlach (p. 30) argues that "*Dipsochelys* taxa are morphologically distinctive but appear to have diverged too recently to be fully reflected in the available molecular data." In his book he speculates that the granitic Seychelles were "colonized from Aldabra 15,000 years ago" (p. 39; in other publications he set the date at 18,000 years ago [Gerlach 2003a:58; Gerlach and Bour 2003:15]). He speculates even further that "[s]mall genetic changes within the last 3–7,000 years" may have given rise to the distinct species that he claims to have rediscovered. This possibility cannot be entirely ruled out, but given the available information on giant tortoises as well as other organisms, it is exceedingly unlikely.

Rather than employ the genetic research to test his hypotheses about morphological differences, the author decides that morphological differences are determinant, and he discounts widely held concerns about the remarkable intra-specific variability and plasticity of shell form, shape, and size. The earlier assertion in the book's introduction, that external features cannot be used to distinguish the three geographically separated clades of giant tortoises (Galápagos, Mascarenes, and Madagascar/Seychelles), taxa that are widely agreed upon, becomes even more noteworthy; for now we are told that external features can be used to distinguish species that are not generally accepted! Information derived from less-than obvious processes (like plots of eigenvectors) is presented with the scantiest of explanations (not to mention sample sizes that are inconsistent between text and legends; e.g., tables 1–2, figs. 13–14). Yet, these procedures (often based on debatable assumptions) form the basis for the author's selection of the species and names to be recognized. As has been pointed out elsewhere (Bour 2004), there are significant inconsistencies in the various hypothetical phylogenetic schemes presented (figs. 9, 36, 38).

The many details on morphology presented in the third chapter, particularly the comparative illustrations of various bony elements (figs. 44, 46–50), would have been considerably more valuable had they been accompanied by explanations not only of how the measurements were taken, but also the provenance, sex, size, etc. of the specimens measured and illustrated. Most hobbyists know that the size, shape, and relative proportions of a tortoise can be distorted—sometimes greatly—when it lives under certain conditions. Despite statements about allometric and isometric growth (pp. 41–45), much more information and analysis than is provided in the book is required to evaluate and understand these phenomena in the tortoises. Shapes and patterns of neural bones are notoriously variable in many chelonians (Pritchard 1988), so generalities about these features (p. 45) must be taken with great care, particularly when only small samples (e.g., two specimens per taxon) are available. Likewise, generalities about cranial morphology (p. 46), and suggestions about some tortoises having a "grinding action" during mastication—particularly when specimens are incomplete (and the samples on which the study is based are not explained)—need to be evaluated with caution. How much Crumly's (1982) seminal study of tortoise crania contributed to the book's description of giant tortoise skulls is not explained. Generalities about bony elements, and processes involved in their ontogeny, that are based on unspecified specimens, and evidently small numbers of specimens for species whose existence is not widely accepted in scholarly circles, must be considered with caution. In contrast to the lengthy details on bony elements to which the majority of the chapter on morphology is dedicated, the sections on skin, digestive system, penis, and heart are remarkably short and abbreviated. The intriguing question of gigantism is left to a couple of paragraphs.

The chapter on taxonomy occupies a quarter of the book. It begins with a reproduction of the fascinating cover from *The Illustrated London News* (ILN) of 5 July 1875, which shows two giant tortoises from the Seychelles. In his legend to this figure, the author determines that one of these tortoises was a female of one species and the other, a male of another species—a feat few people would attempt on the basis of just this old wood engraving.[iii] He lists six species in the genus "*Dipsochelys*," two of which are extinct species known from Madagascar. In addition to the Aldabra tortoise, called "*Dipsochelys dussumieri*" by the author, three other "species" are listed for the granitic Seychelles islands, of which he suggests one may be extinct. Additionally, five species of *Cylindraspis* are listed, this group being native to the Mascarene Islands. It is incredible that the binomial used most commonly in the hobbyist, and also scientific, publications for nearly fifty years to refer to the Aldabra giant tortoise—*Geochelone gigantea*—appears only a few times in the book, and is totally absent from the synonymy that is proposed (p. 67). This, and synonymies for other supposed species, is likely to greatly confuse the understanding of tortoise nomenclature and taxonomy.

The photographs of rarely seen type specimens are valuable, and a wealth of information is provided in the species synopses. However, it is bewildering that the nomenclature and taxonomy used in the book contradicts what has been used after careful research published recently in mainstream scientific journals (e.g., Austin and Arnold 2001; Palkovacs et al. 2002, 2003; Austin et al. 2002, 2003; Karanth et al. 2005)—even more so in that the author of the book is also a co-author on three of these peer-reviewed papers. Moreover, Roger Bour, an earlier proponent of resurrecting various names in disuse, and also author of the new name "*Dipsochelys arnoldi*" (Bour 1982) is a co-author of a recent study that concludes that only one species, *gigantea*, exists and has existed on Aldabra and the Seychelles (see Austin et al. 2003). Since the writings on giant tortoises by the early herpetological giants of the 18th, 19th and early 20th century, there has been a general realization that although species may be typified by certain external characteristics, there is still considerable intra-specific variability in skeletal, soft tissue, ecological, and behavioral characteristics (e.g., Rothschild 1915:428). In numerous parts of Gerlach's book, this general biological notion of the importance of intra-specific variability does not seem to be accepted. Indeed, as colleagues familiar with his work have observed, the author's rejec-

tion of recent findings from mainstream scientific research, even those with which he has collaborated as a co-author (e.g., Palkovacs et al. 2002, 2003; Karanth et al. 2005), suggests he has little faith in the scientific method, at least when the results contradict his conviction that he has rediscovered and saved the last remnants of two species of Seychelles tortoise (Gerlach 1998b).[iv]

While the tortoises of the Mascarenes are not the main subject matter of the book,[v] it is important to point out several anomalies. The claim that each of the three major Mascarene islands (Mauritius, Réunion, and Rodrigues) had two sympatric species of giant tortoises (p. 36, fig. 38) is a *faux pas* (that is corrected later on in the book). It contradicts recent scholarly research (Austin and Arnold 2001; Austin et al. 2002), which confirms two pairs of sympatric species, one on Mauritius and one on Rodrigues with but a single species on Réunion. The nomenclature and "phylogenetic scheme" presented for these animals (pp. 38, 99 ff.) are also at variance with recent studies published by various scholars in widely available professional journals (e.g., Austin and Arnold 2001; Austin et al. 2002). In the last named study, Roger Bour, author of *Cylindraspis borbonica* (1978), has accepted that his name is a junior synonym for *C. indica* Schneider, 1783, the extinct tortoise from Réunion. Yet, Gerlach's book lists only *C. borbonica* for the Réunion tortoise (p. 99), with no explanation of the other (older and available) names that have been applied (see Austin et al. 2002:284).

In summarizing the nomenclatural complexities involving giant tortoises, Bour (1984b:282–283) concluded that "[t]he peak of entanglement appeared with the publication of Lord Rothschild's (1915) work. But we willingly admit that this enthusiast did good both as a protectionist and popularizer." Perhaps he misjudged recent events. In the end, an enormous amount of time and effort has gone into debating what names to use for the giant tortoises of the Indian Ocean, a dubious situation this book will help sustain. "If all the time we all spend worrying about tortoise names were spent investigating their biology, they would be a very well studied group!" (Arnold *in litt.* 24 August 2005).

The chapter on ecology brings together much of the unique field work done on Aldabra Atoll over several decades, and the author rightly emphasizes the main limiting factors for tortoises on the Atoll: water, food, and shade. Yet, this chapter could be stronger. The narrative about shallow pools influenced by tidal ebb and flow (p. 119) confuses different types of phenomena affecting very different types of water bodies. Activity patterns of tortoises, at least on Aldabra and Curieuse, vary with size and sex of the animal, as well as with environmental conditions (Frazier 1972; Hambler 1994), so it is not clear how to interpret the book's generalized activity graphs—with no explanation of the individuals and conditions sampled (figs. 125–126; republished in Gerlach 2005). Thus, reported "differences in thermoregulatory behaviour between the three species of *Dipsochelys* giant tortoise" could be easily explained by differences in tortoise sizes and/or environmental conditions (e.g., Frazier 1972; Hambler 1994), but since these details are not provided one can only guess. The claim that "[r]egular basking behaviour has been observed in *D. arnoldi* only" contradicts extensive observations of giant tortoises on Aldabra (where the occurrence of "*Dipsochelys arnoldi*" has yet to be affirmed), and elsewhere, over periods of differing climatic conditions, where "basking" does occur, although not commonly. The descriptions of feeding are useful, although not without deficiencies. If the extensive work on wild tortoises on Aldabra is considered, it is clear that generalities about diet vary from place to place, from season to season, and between individuals, especially between different size classes (e.g., Frazier 1972; Gibson and Hamilton 1983). Hence, Gerlach's claims about species-specific differences in feeding behaviors (p. 139) need to be viewed within the context of the tremendous variation that occurs on just Aldabra. His interpretation that males mounted on other males are exhibiting conflict behavior (p. 135) is novel, and may be a gentlemanly way to avoid revealing that the extremely high libido in some male tortoises can result in them mounting just about anything, with just about any orientation (Frazier 1972). The concepts of "asocial" and "antisocial" behaviors (p. 135) are, despite the author's implications, very different.

Observations that age at maturity and reproductive effort vary with population density (pp. 138–139, 143) are critical, for they show yet again how plastic the biological features of these animals can be, with remarkable variation in physiology, growth, behavior, and morphology—all within individuals from the same population. Photos presented in support of species-specific differences in hatchling giant tortoises (figs. 145–147) are misleading, for the individuals shown are of different ages and sizes; the photo labeled as "*Dipsochelys arnoldi*" is comparable to some recently emerged hatchlings on Aldabra. Generalities about tortoises spending the first four years of their lives living in rock crevices (p. 147), while fascinating, do not tally with observations on Aldabra, nor with the fact that some of the areas on the Atoll with the highest density of tortoises are characterized by a pavement type of limestone, with a paucity of crevices (Grubb 1971). Speculation about rates of gene flow on Aldabra (p. 150, fig. 149) must be tempered with adequate studies; moreover, the displacement of animals in a dense population where successful reproduction is low is not the same as gene flow. Besides a number of points that are debatable, the order of ideas in this chapter is not always easy to follow.

As Bour (2004) explained, the chapter on history of giant tortoise discovery would seem more appropriate at the beginning of the book. In addition to the publications that Bour (2004) listed as missing from the historic treatment, a number of others could be added, including North-Coombes' (1991) intriguing account of early records from Rodrigues. Much of the historic information presented on the Seychelles seems to have come from Fauvel's (1909) impressive compilation of unpublished historic documents, although this detail is not mentioned in the book. The speculations about two sympatric tortoise species on the island of Mahé at the time of European discovery (pp. 162–163) are apparently supported primarily by the authors' intense conviction that he has rediscovered at least two species thought to have been extinct. The map depicting giant tortoise localities on Madagascar (fig. 157) is apparently, like several other parts of the book, based on the extensive research by Roger Bour. Unfortunately, it omits the northwestern localities (see Bour 1985: map 2, 1994:173, fig. 3), those that may be critical for explaining colonizations by these highly specialized tortoises onto the islands to the north (Austin et al. 2003).

The penultimate chapter on conservation is short, as Bour (2004) has pointed out. That captive rearing dominates its nine-and-a-

half pages, with enormous detail paid to tortoises in captive conditions, clearly shows the author's priorities. Yet, Gerlach himself admits that the long history of captive breeding has "played little part in conservation of Indian Ocean giants" (p. 179).

The final section, bibliography, brings together a useful compilation of sources of information on Indian Ocean giant tortoises from hobbyist magazines, unpublished theses and reports, old and hard-to-find writings, and also from the mainstream academic literature. The fact that several valuable publications were not included (Bour 2004) is not surprising given the vastness of the subject. Nonetheless, if the extensive scientific work done on Aldabra is to be considered, a number of scholarly publications would need to be included in a bibliography of Indian Ocean giant tortoises.

The bountiful color photos in the penultimate chapter, and throughout the book, are very effective in showing the beauty of the Seychelles and its wildlife, as well as providing an alluring travelogue style. Speculations on the origin and evolution of tortoises in the western Indian Ocean as well as other topics provide plenteous themes for years of careful research to test and tease apart the various assumptions and scenarios. Yet, assertions throughout the book, ranging from the stories of certain tectonic movements to variability in chromosomal base pairs, need to be evaluated on the basis of the best available information, not the author's passionate views regarding the creation of these captivating reptiles.

News that new species have been discovered, or "rediscovered," is routinely met with great interest. When combined with the need to save the animals from extinction, the topic takes on great public appeal, garnering support from diverse sectors, particularly the very dynamic community of tortoise breeders and hobbyists (e.g., Bruckers 1998; Devaux 1999), and often involving international celebrities, such as, in this case, Sir David Attenborough (Gerlach 2002). At one level there is an undeniable charm in being able to rediscover lost species and save them from extinction. However, the unrelenting insistence throughout the book to promote the existence of various living species of giant tortoise in the Seychelles flies in the face of diverse sources of scientific evidence and distracts from those contributions that the volume could make. Some conservationists in these incredible islands have pleaded for leaving the tortoises alone and getting on with other, more pressing priorities (Shah 2003).

As a continuation in the long line of popular literature on chelonians, this book is sure to be well-liked among the large, active community of herpetological enthusiasts,[vi] particularly tortoise aficionados. It may not fare so well in the scholarly community, where there is, early or late, a requirement for rigorous defense of claims and theoretical constructs, the clear separation of factual information from speculation, and theoretical discussion based on sources that have survived some form of academic review and critique. The book does make contributions, but tortoise students struggling to apply the scientific method may yet have to wait for that much-needed synopsis of Indian Ocean tortoises.

Notes

[i] Several researchers have expressed similar concerns about other publications by the same author on subjects including birds, tortoises, terrapins, land snails, and plants of the Seychelles (e.g., Hambler 1997; Beaver, *in litt.* 8 August 2005; Mortimer, *in litt.* 31 July 2005; 26 Jan 2006).

[ii] *Phelsuma* is "the scientific journal of The Nature Protection Trust of Seychelles [NPTS]," an active NGO in the Seychelles established by Ron Gerlach, the author's artist father, and passionate conservationist who lives on the island of Silhouette, Seychelles (Devaux 1999:20). This serial has published 12 volumes and 147 articles since its inception in 1992, where J. Gerlach has a prodigious publishing record, with 34% of all articles authored either solely or jointly by him; his work load also includes the editorship of the journal (<http://members.aol.com/jstgerlach/phelsuma.htm>), as well as running the Indian Ocean Biodiversity Assessment (Gerlach 2004; <http://members.aol.com/jstgerlach/jg.htm>).

[iii] For information on 19th century illustrations in the ILN see http://www.ilnpictures.co.uk/showpage.asp?showdocumentid=192

[iv] The tortoises identified as "the last remaining individuals of two nearly extinct species" are popular attractions for tourists, some of whom take helicopter rides from the main island of Mahé to Silhouette to see the NPTS tortoise project and facilities (Devaux 1999:20). The NPTS also organizes tours to view the tortoises and terrapins of Seychelles and solicits funds for adopting various tortoises kept by the Trust (Gerlach 2002).

[v] Indeed, the book's title "*Giant Tortoises of the Indian Ocean. The Genus* Dipsochelys *inhabiting the Seychelles Islands and the extinct giants of Madagascar and the Mascarenes*" could be misunderstood to mean that the Mascarene tortoises are part of the genus "*Dipsochelys.*"

[vi] Indeed, this attractively produced book is the product of the very active hobbyist community in Germany.

The title of this gracefully written biological history belies the content of the book. The tortoises of the oceanic islands of the Pacific and Indian Oceans have hardly been sheltered from the rapacious predation of man. The author, Paul Chambers, is well aware of this devastating harvest. The title, of course, refers to the shell and its protective aspect prior to the arrival of humans. Similarly, he well recognizes the diversity of these insular giants, treating them as a single entity in the title because that is how sailors, colonists, and naturalists viewed them upon their first discovery and during the early centuries of tortoise-man interactions.

This book is not a conservation advocacy, although the conservation of giant tortoises is a core aspect of the narrative. It is impossible to discuss giant tortoises without examining man's rapacious behavior. This aspect of tortoise history is depressing reading, because all of us are aware of the outcome and can imagine the cruelty of harvesting and transport. Chambers presents the information factually, neither over- nor understating the extent and nature of tortoise harvesting. He reveals the stuttering start of tortoise conservation. Protection was a long time in arrival and remains in a fragile state in Aldabra and the Galápagos.

The narrative is organized into seven sections: Discovery; Inspiration; Decimation; Obsession; Pets; Recovery; In the Blood. Each section consists of two or more chapters. "Discovery" provides a history of the discovery of the giants by early navigators. "Inspiration" details the early taxonomic history of the giants. The focus, however, is the influence of the Galápagos tortoises on Darwin's developing thoughts on evolution. These chapters are delightful reading and most thought provoking, and I highly recommend them to anyone with slightest interest in Darwinian history. "Decimation" describes the decline and extinction of Indian Ocean tortoises and the impact of the whaling fleet on the Galápagos populations. Albert Günther and Walter Rothschild are the main figures in "Obsessions." I was aware of Günther's impact on giant tortoise taxonomy, but it was a delightful surprise to discover his crusading efforts to protect them, particularly the Indian Ocean ones. I share Chambers' assessment that his effort to establish breeding colonies outside a species' native habitat was misguided and not a viable solution to their conservation. Similarly, the current captive colonies of turtles and tortoises are equally misguided conservation efforts, serving the pet-keeper syndrome but not conservation of chelonians.

"Pets" examines the history of a few individual captive tortoises of exceptional longevity. Chambers' style here is polite and thorough investigative reporting. He also demonstrates that Darwin did not personally bring Galápagos tortoises home from his Beagle cruise. "Recovery" details 20th century attempts and successes in giant tortoise conservation. "In the Blood" examines current systematic and nomenclatural issues. Such matters are seldom of interest to laity or, for that matter, to most biologists. The telling here is thorough, yet a relaxed and honest report of recent (through 2003) scientific studies that reveal the survival of a single Indian Ocean giant (*Aldabrachelys gigantea*) and the persistence of a dozen-plus genetically distinct populations of Galápagos *Geochelone*.

I urge everyone with the slightest interest in tortoises and/or the history of biology to read Chambers' "A Sheltered Life." It offers a fascinating glimpse of Charles Darwin and the influence of tortoises on his development of evolutionary theory, revelations of Albert Günther as a conservationist, and many more aspects about giant tortoises.

Herpetological Review, 2006, 37(3), 374–376.

Amphibians of the Pacific Northwest, edited by Lawrence L. C. Jones, William P. Leonard, and Deanna H. Olsen. 2005. Seattle Audubon Society, Seattle, Washington (www.seattleaudubon.org). xii + 227 pp. Softcover. US $19.95. ISBN 0-914516-16-7.

Field guides to the faunas of particular places tend to assort into two different models, largely depending on the number of species they encompass. The classic Peterson bird guides, for example, tend to have large numbers of small pictures, grouped many to a page, in order to cover the myriad species. Necessarily, these guides have only limited text that serves little else than to provide field characters for identification. There are lots of warblers. For smaller faunas in smaller regions than half a

continent, the Peterson approach would make for a pretty slim volume and thus the other model for a field guide or handbook is to devote several pages to each species and provide some depth and biology to the treatment. For the 47 species of amphibians in the Pacific Northwest of North America, this is the way to go and the result is a visually stunning photographic guide to the salamanders, newts, frogs and toads from Alaska to northern California west of the Rocky Mountains.

This guide is the successor to the 1993 "Amphibians of Washington and Oregon" by W.P. Leonard and co-authors. There are significant differences between the older book and the new, even though the layout and reliance on photographs is much the same. The geographic coverage is expanded, the number of species is expanded, the number of pages is expanded, and the number of authors is greatly expanded. There are flaws but the beauty of the illustrations will persuade anyone with a love for amphibians to get a copy.

The book's scope includes amphibians from Alaska, Yukon, British Columbia, Washington, Oregon, Idaho, western Montana, a small portion of extreme southwestern Alberta, and California north of Santa Cruz and west of the Siskyou Mountains. This constitutes a nicely definable biogeographic province with a fauna distinct from the drier American southwest, the central North America prairies, and most of the northern boreal forest. The maps, though, are a disappointment. The older book had an accurate rendering of the coastline of Washington and Oregon and showed county lines so that the extent of the blob distributions could be reasonably well located. The maps in the new book have an extremely vague and inaccurate portrayal of the coastline and only the state and provincial boundaries as landmarks. For all those many similarly stripy salamanders, knowing where you got it is the essential key to knowing what you've got but the maps make that very difficult. A few rivers at least would be valuable to help us get our bearings. These are not dot maps and the blobs are wrong some of the time. There are no records of Pacific Treefrogs in the Chilcotin and Nechako regions of British Columbia that lie west of the Fraser River. The Coastal Tailed Frog does not stop that far from the British Columbia-Alaska border. The Boreal Chorus frog has a much more extensive distribution in the Peace River district of northeast British Columbia than is depicted. The maps were compiled from maps published in other sources, which strikes me as having the unfortunate spin-off of perpetuating any errors those other maps might contain. Compounding this geographical vagueness, the locations of the photographs are identified only by state and county (there are so few photographs of animals from north of the 49th parallel that it's hardly worth the mention). I find this practice more annoying than helpful for I don't know where most of these counties are and there is no map to tell me.

The older book had five authors, the new has 33. Each section and species account in the new book has its own author or co-authors. Writing text for a popular guide is not at all the same as writing for the technical scientific literature. It is not surprising that some of the authors in this book demonstrate more adroitness than others. Deanna Olson's overview of frogs and toads is nicely balanced and appealingly written; David Darda turns a few good phrases in his overview of amphibians. Less successful are the piece on biogeographic patterns by Bruce and Gwendolyn Bury and the discussion of taxonomic and genetic diversity by Steven Wagner, both of which seem unable to package the information in a way that would engage and inform a lay reader. With talk of elements and regions and species names all in a row, the Burys' essay does not give much of a sense of why species are where they are so much as merely to point out where they happen to be. Wagner has an admittedly difficult task in explaining the arcane lore of modern taxonomic research but without knowing the histories of the usage of various names, it doesn't much make sense. Unless you knew that *Plethodon vandykei*, *Aneides ferreus*, *Rana aurora,* and *Rana pretiosa* each once were used to encompass populations that now are recognized as different species, there is nothing particularly interesting in *P. idahoensis*, *A. vagrans*, *R. draytonii,* or *R. luteiventris*. They are just names. Whether spadefoots are *Spea* or *Scaphiopus* makes no difference to identifying one if you catch it, and the issue confuses almost everybody. This applies likewise to the generic assignment of the Pacific Treefrog. Wagner evidently recommends *Hyla regilla* but the rest of the book uses *Pseudacris regilla*.

With so many authors each writing some small bit, unevenness in the quality of the writing is inevitable, but that's why we should have editors. Yet, noticeably and regrettably, repetitions and apparent contradictions appear throughout. This is especially a problem in the introductory sections about the biology of amphibians. "Anura" is defined as "without tail" on both page 6 and page 12. "Explosive breeding," which has long struck me as an unfortunate term conjuring images of frogs bursting apart, eggs flying everywhere, is defined on page 11, on page 12, and again in the glossary on page 222. Page 20 mentions chytridiomycetes and and oomycetes without defining them at all. They are fungi. *Saprolegnia* is in the glossary, defined as a fungus without mentioning that it is an oomycete. Page 6 says there are 15 species of frogs native to the region; page 12 says there are 17 species of frogs found in the region. This is true because two species are not native but there is the appearance of contradiction. Conservation concerns about amphibians are mentioned in a section on laws and conservation (pages 4 and 5), again on pages 8 and 13, and again in an essay on declining amphibian populations (pages 20 and 21). You'd think that the most interesting thing about amphibians is that there is progressively fewer of them. I tend to think that there are a great many interesting things about amphibians, including their morphology, behavior, physiology, sensory systems, and development, that could have had more wording devoted to them.

The amount of natural history knowledge and specific information in the species accounts is terrifically impressive but they, too, have their share of textual idiosyncracies. Some species lengths are given as TL, some as SVL and, for some frogs, SUL. Poor Reader has to use the glossary at the end to fathom that these are Total length, Snout-to-vent length, and Snout-to-urostyle length, respectively. Some, but not all, of the species accounts have interesting tidbits of information included, such as that spadefoots make people sneeze and Rocky Mountain Tailed Frogs swim by alternately kicking with their hind legs (Coastal Tailed Frogs do, too). Many, though, repeat taxonomic changes and items of conservation status mentioned elsewhere. There is no guide for what identifying characters to look for on the squirming animal you may have in hand, and there are no keys. The only diagrams showing field identifying characters are at the back of the book, along with

the glossary. I think this makes the book more difficult to use, especially when a species account suggests counting costal grooves between adpressed limbs and the only guides for what those may be are in the glossary.

Of all the species covered, I think the Wood Frog is the one hard done by. The photographs of adult Wood Frogs are all from the same county in Michigan, except for the tadpole which is from Tennessee. Wood Frogs from British Columbia, Yukon, and Alaska don't look like these. Wood Frogs from the northwest are mottled grey and black and have much shorter legs than those fine, uniformly light brown frogs from Michigan that do not even have the bold mid-dorsal stripe so common among northwestern individuals. Furthermore, Wood Frogs do not range so far south in British Columbia as is depicted on the map. All this may lead to even more confusion than there is already among records of Wood Frogs and Columbia Spotted Frogs in British Columbia. The species account also mentions the Wood Frog's famous freeze-tolerance but incorrectly states that it floods its cells with glucose. Glucose floods the extracellular fluid, serving initially as antifreeze and then as cryoprotectant once the extracellular fluid does freeze so that the cells do not dehydrate or suffer physical damage. I suppose this is less off the mark, though, than the text on page 13 implying that Wood Frogs freeze until spring thaw.

Nevertheless, the book is clearly intended to be used primarily as a picture key. It's the photographs that are its major attraction and the photographs are marvelous. These are many of the best photos of amphibians you are likely to find anywhere. Every species but one is illustrated with at least five photographs, and usually six, of stellar quality. Only the Scott Bar Salamander, *Plethodon asupak*, has only two photographs of it but the species is so new and so rare that to see any photographs of it at all is remarkable. All species with tadpoles or larvae have those illustrated, too. There are even photographs of egg masses for many species, mainly frogs. The work and diligence that went into compiling this set of photographs is truly commendable.

In most cases the photographs show much of the range of variation with the species. Oh, there are some peculiar choices of photographs, to be sure. Four photographs of transformed adult *Dicamptodon copei* are given although the species rarely transforms. Three very similar photographs of three very similarly red *Rana draytonii* are provided, which strikes me as odd because I have never found such vibrantly colored animals among any California Red-legged Frogs I've ever caught. The Tiger Salamanders at the top and bottom of page 39 look like the same individual. Likewise, there are two photographs of *Rhyacotriton cascadae* on page 59 on what must surely be the same rock and be perhaps the same individual. And the Wood Frogs are from Michigan.

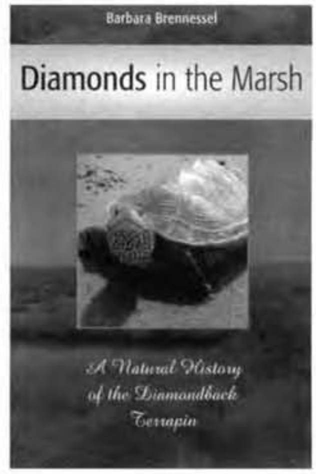
However, the photography shows real skill and artistry. The animals are in natural settings and they look unstaged, notwithstanding the mild abuse needed to get a newt into its unken defensive posture. Take a look at the salamanders on page 145, or egg mass and tadpole on page 176, or the stunning shot of newt larvae about to hatch on page 80. Shots like these make this a beautiful book.

The *Amphibians of the Pacific Northwest* is a well produced and beautiful little book. It entices you just to look at the pictures and get a feeling for these animals. It might not prove to be the easiest of field guides for an amateur herpetologist but it is certainly worth having.

Herpetological Review, 2006, 37(3), 376–378.

Diamonds in the Marsh – A Natural History of the Diamondback Terrapin, by Barbara Brennessel. 2006. University Press of New England, Lebanon, New Hampshire (www.upne.com). xii + 219 pp., 16 pls. Hardcover. US $26.00. ISBN 1-58465-536-4.

MATTHEW P. BETTELHEIM
Nomad Ecological Consulting, 832 Escobar Street
Martinez, California 94553, USA
e-mail: mbettelheim@nomadecology.com



The April 2006 publication date of Barbara Brennessel's *Diamonds in the Marsh*, a treatise tackling the natural history of Diamondback Terrapins (*Malaclemys terrapin*), conveniently coincided with the passing of House Bill 4296 in the State of South Carolina on 15 March, 2006, prohibiting the commercial harvest of Diamondback Terrapins, and the passing of House Bill 980 in the State of Maryland on 21 March, 2006. Maryland's bill, originally written to prohibit the commercial harvest of terrapins altogether, instead passed with amendments requiring Maryland's Department of Natural Resources "to prepare a fishery management plan for diamondback terrapin [and...] adopt regulations governing terrapin resources and the catching of terrapin consistent with certain recommendations of the Maryland Diamondback Terrapin Task Force..." (MD HB980; March 21, 2006). Both Brennessel's book and the enactment of these two statutes regulating the harvest of terrapins are a boon—if not a blessing—for this species that once graced tables throughout the United States as the main ingredient in soups and stews.

Dating back to the 1500s, European colonists recognized and took advantage of terrapins in the New World, utilizing this bountiful supply of flesh (and eggs) as a food source not only for themselves, but also for servants, slaves, and pigs. Between the early 1800s and the 1850s, the demand for terrapin skyrocketed such that the price for a dozen large terrapins had risen from $4 to as much as $100 or more. Terrapin meat was shipped around the world to Paris, Berlin, and South America. By the early 1900s, however, the demand for terrapin waned as diamondback populations plummeted under the pressure of the overharvesting already underway (Brennessel 2006).

A comprehensive natural history such as *Diamonds in the Marsh* is an invaluable tool in the study and conservation of a species, and can provide a solid foundation for future research, conservation, and management decisions. Brennessel effectively pulls together the bulk of literature on the diamondback and communicates it to the reader in a generally clear, uncluttered fashion so as to make it not only a resource for researchers, but also an interesting read for reptile aficionados.

Chapter 1 covers everything one would expect in a species' natu-

ral history account, neatly presented. It is followed in Chapter 2 by a breakdown of the diamondback's range along the Atlantic and Gulf coasts, although this is organized in a muddled combination of terrapin populations, biogeographic regions, and/or states. This discussion of the diamondback's range is further complicated by the rudimentary map (Figure 1.9; p. 25) that offers little more than dashed lines demarcating the range of each subspecies overlain on a bare bones map of the coastal states from Massachusetts to Texas. There are no state names, oceans, bays, capes, state capitols, or major cities as reference points, making it difficult for those interested in orientating themselves with the lay of the land as they are introduced to the species' range.

In Chapters 3 and 4, Brennessel gives a thorough overview of the diamondback's reproductive cycle and first years of life, including sex ratios, sexual dimorphism, courtship and mating, nesting, nest site selection and construction, egg and clutch sizes, incubation, temperature-dependent sex determination, emergence, the so-called "lost years," and headstarting.

Chapter 5 offers a welcome respite from data-driven science. Here, the author and her readers have the opportunity to stretch their legs, and Brennessel does so with gusto. In the first ten-or-so pages, we're run through a gamut of legend and lore, from the tale of Brer Tarrypin of Uncle Remus fame to the Native North American's Great Turtle, followed by a discourse on the terrapin as a main course. We're peppered with recipes, presidential gossip, and accounts of its epicurean rise to fame and fall from grace, followed by accounts of other sources of mortality: predation, pollutants, bacteria, aquaculture, road mortality, and by-catch, to name a few.

Two omissions from this chapter are noteworthy, however. First, there is no mention of the Green Turtle (*Chelonia mydas*) or the Pacific Pond Turtle (*Clemmys marmorata*), two species that were extensively harvested simultaneously with the harvest of diamondbacks (Ernst et al. 1994) and that often appeared alongside the Diamondback Terrapin on menus (the Pacific Pond Turtle restricted to the Pacific Coast). True, the book's focus is on the Diamondback Terrapin, but a comparison between the harvests would have offered some perspective, especially given the fact that the harvest of Pacific Pond Turtles was likely inspired by the harvest of diamondbacks that by mid 1800s had been underway for more than a century. Second, there is no mention of the repeated (and failed) attempts to introduce diamondbacks to the West Coast (Smith 1895; State Board of Fish Commissioners of the State of California 1900;Taft 1944; Brown 1971; Jennings 2004) to supplement the waning supply of Pacific Pond Turtles in California in the late 1800s and early 1900s. These failed introductions show how truly influential the popularity of the Diamondback Terrapin was from coast to coast.

Brennessel's closing chapter soberly brings us back to the present, laying out not only what we have learned to date, but also how much more we need to learn for us to conserve these declining populations of Diamondback Terrapins. By-catch reduction devices and turtle exclusion devices have proven effective in excluding terrapins from crab pots, for example, but the regulations and incentives in place between states to require their use commercially or privately vary, if they exist at all. Additionally, the impacts of the commercial and private harvests on terrapins need to be considered in establishing and enforcing size limits, moratoria, and fishery management plans. These, however, are tricky roads not easily navigated.

As a resource for researchers, *Diamonds in the Marsh* is somewhat constrained by its design—likely a handicap necessary to attract the non-scientists. The table of contents requires a bit of intuition; Chapter 1, "A Decidedly Unique Creature," describes everything from the species' geographic variation to internal anatomy to taxonomy, whereas Chapter 5, "A Clear and Present Danger for the Most Celebrated of American Reptiles," covers Native American legends, the historical harvest of terrapin, natural predators, by-catch in crab pots, and pollutants (among other topics). Likewise, the index is somewhat bare. In flipping through the index, for example, one would not realize that there was any discussion of headstart programs for Pacific Pond Turtles or a retelling of the tale of Uncle Remus' Brer Tarrypin (there are).

Several gross errors are worth mentioning. The second half of the book is scattered with spelling and typographical errors (e.g. "aqualculture," or "habit" instead of "habitat") that should have been caught at the copyeditor's desk. But without question, my biggest complaint about *Diamonds in the Marsh* is its poor-quality photographs. Although most of the black-and-white photos are sharp or passably so, almost all of the color plates are either pixelated or grainy. Worse, even the photographs on the book jacket cover (front and back), as well as the frontispiece—all depicting the Diamondback Terrapin itself, no less—are visibly pixelated. Fortunately, William E. Davis' illustrations of diamondbacks—based on dead specimens, if I understand correctly—are nonetheless surprisingly and refreshingly life-like and expressive, penned with an eye for detail reminiscent of the herpetological plates found in Louis Agassiz's *Contributions to the Natural History of the United States of America* (1857). Their inclusion as chapter head pieces should be commended.

At times, Brennessel does allow her narratives to spill over, following tangents about the annoying resident insects to be found in the Atlantic salt marshes, or in stories and asides to the reader that seem either out-of-place or too familiar in what is, ultimately, a natural history of the Diamondback Terrapin. Still, she is effectively thorough in her coverage of the Diamondback Terrapin's natural history. Considering the broad readership she is appealing to, she keeps in-text citations to a respectable minimum to avoid cluttering up the narrative and, with a few exceptions, provides the necessary citations to direct inquiring minds in the right direction. Overall, Brennessel arrives at a good balance between writing for the scientist and writing for the general public.

When all is said and done, most of my criticisms are merely cosmetic. Brennessel accomplished what she set out to do—take on the arduous and daunting task of synthesizing the extant literature on Diamondback Terrapins and weave it into a natural history account that is both informative and inspirational. *Diamonds in the Marsh* does not fall short of this goal, and will no doubt inspire future generations of herpetologists to take an interest in the Diamondback Terrapin at a time when such help is needed most.

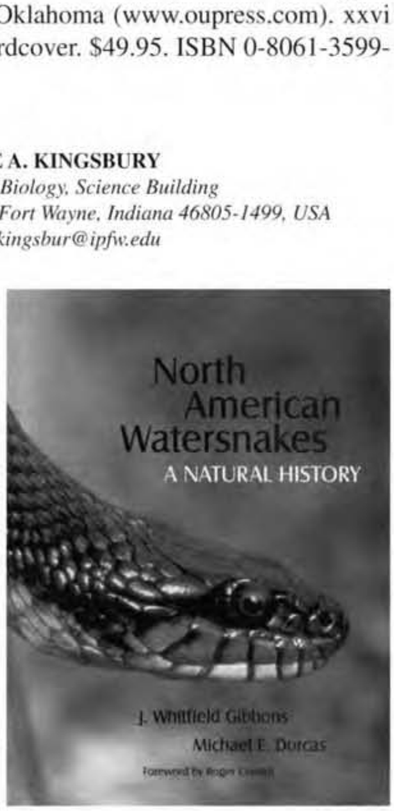
BRUCE A. KINGSBURY
Department of Biology, Science Building
Indiana-Purdue University, Fort Wayne, Indiana 46805-1499, USA
e-mail: kingsbur@ipfw.edu



This is a comprehensive treatise on *Nerodia*, *Regina*, and *Seminatrix*, the watersnakes of Canada, the United States, Mexico, and Cuba. The genera covered in this publication were selected both because of systematic association and aquatic affiliation. Species such as the aquatic, but phylogenetically distant, *Faranica abacura* and *Agkistrodon piscivorus* were not covered, nor were any of the closely related but more terrestrial *Thamnophis*. The University of Oklahoma Press has also published an earlier volume, *The Garter Snakes* (Rossman et al. 1996), partly explaining the exclusion of the last of these genera from this volume.

Following the Introduction, the bulk of the book is divided into two sections. Part One, "Watersnake Biology," contains four brief chapters, each covering a broad topic. Chapter One is a brief overview of the taxonomy and systematics of the group. I would have liked to have seen more discussion of how these natricine genera are anchored among other colubrids. Instead, the authors directed more effort at explaining relationships between the species within the group. Included are a brief review of the relatedness of the genera in question to one another, and the justification for certain taxonomic decisions made in the book. Further details of relationships and of the taxonomic rationale employed are found in the individual accounts later in the text. This chapter also includes a table listing known fossil watersnakes.

Chapter Two is a review of techniques that have been employed to study watersnakes in the field. Chapter Three is an exploration of more general aspects of the biology of watersnakes, covering topics such as diet, parasites, body size, and reproduction. Finally, Chapter Four is a look at conservation issues involving the watersnakes. Snakes, as we know, are a group much maligned, but watersnakes are targeted with particular enthusiasm. Highlighted are the various efforts to glorify or justify the killing of watersnakes, including their purported competition with us for gamefish, or for being mistaken, no matter their true identity, for being "moccasins" – poisonous, and thus a great threat to all. This chapter also includes a tabular review of the legal status for those species listed at the state or federal levels.

Part Two includes species accounts for *Nerodia*, *Regina*, and *Seminatrix*. This section opens with range maps for each species, depicted by county, and color-coded to distinguish between sources of county record information. Precedence was given to museum records, but other records were included when these were not available. The maps do not convey any information about the most recent date that the species was observed, thus patterns of decline are not evident. However, the authors went to great pains to provide a source for all of the records they used (Appendix 3). Range maps are followed by keys for *Regina* and *Nerodia*, the two groups having more than one representative. Attractive color plates showing all of the species and subspecies are provided in the center of the book. Though small, they serve to illustrate the diversity and distinctiveness of this group of snakes.

Each of the species accounts begins with scientific name, the most widely used common name, and then a list of the subspecies. Sections regarding the identification, systematics and distribution of the species follow. "Description" details the morphological features defining the species and permits subspecies to be distinguished. "Taxonomy and Systematics" provides an overview of the taxonomic history of the species and details data bearing on both inter- and intraspecific relationships. A separate "Etymology" section addresses the origin of the specific and subspecific epithets and "Common Names" provides a thorough explanation of alternative common names. "Geographic Distribution" details the known range of the species, and sometimes the areas occupied by subspecies. "Fossil Record" summarizes the fossil records attributable to each taxon. The remaining sections relate to the biology of the species. Depending on the amount of published literature available for each species, different sections may be longer or shorter. "Habitat" characterizes wetland and upland requirements and includes particulars of habitat features needed for activities such as foraging and hibernation, as well as comments on seasonal activities as they relate to habitat use. Depending on the species and the extent to which they have been studied, the "Physiology and Behavior" section may contain details about such topics as thermal physiology, escape behavior, and ecdysis. Patterns of movement are provided in a distinct section, "Activity." What they eat and who eats them is covered in the sections "Diet and

Feeding" and "Predation, Parasitism, and Defense." Aspects of the growth of the individual, reproduction and population biology are each treated in separate sections. Each account closes with the more diverse sections: "Captive Maintenance"—addressing issues related to keeping the species in the laboratory, "Conservation"—highlighting concerns about threats to the species, and the closing section, "Questions and Comments," which provides the authors with a platform to raise research and conservation questions about the species. Both of the authors are well-established academic researchers, but have also shown a willingness to engage with natural resource agencies and the general public to promote conservation.

A final chapter, the Afterword, entitled "Research Opportunities with North American Watersnakes," offers a last examination of where the greatest research opportunities might lie for these taxa. Here the authors acknowledge details such as the taxonomic and systematic challenges remaining for these snakes, the research potential of these cooperative captives, and a plethora of other opportunities and questions. Clearly, though much is known, much remains to be explored.

Last but not least are the appendices and bibliography. Appendix 1 details the synonymies, type specimens, and localities for all of the species covered. Appendix 2 covers scutellation, and Appendix 3 provides a list of the verification sources, by county, for each species, for all of the records used in the figures and text. The first and last appendices should be particularly useful to researchers endeavoring to track down the details of distributions, or where to find a critical specimen. The last section of the book, the "Comprehensive Bibliography," is indeed comprehensive, as evidenced by the 80-some pages of citations. It provides a rich resource for reference hunters.

To conclude, Michael Dorcas and Whit Gibbons have done an excellent job. I would strongly recommend this work to the interested layperson, to students of herpetology, and to professionals seeking a worthy resource for further enlightenment. Gibbons and Dorcas were superbly thorough in their search for published and unpublished information. Their efforts to be as inclusive and current as possible are apparent, and I commend them.

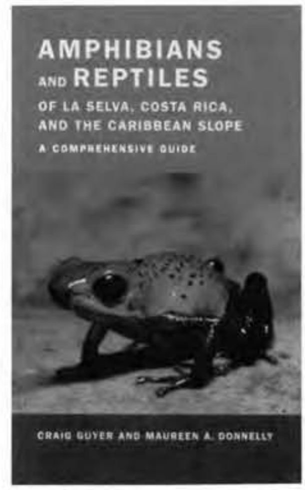
Amphibians and Reptiles of La Selva, Costa Rica, and the Caribbean Slope: A Comprehensive Guide, by Craig Guyer and Maureen A. Donnelly. 2005. University of California Press, Berkeley, California (www.ucpress.edu). viii + 299 pp. Softcover. US $24.95. ISBN 0-520-23759-5.

LARRY DAVID WILSON
Department of Biology, Miami Dade College
Kendall Campus, Miami, Florida 33176-3393, USA
e-mail: lwilson@mdc.edu



Over the years, the Central American country of Costa Rica has come to symbolize the biological promise of the American tropics. This feat has been due, in no small part, to the presence within this country's borders of one of the premier tropical field stations in the world, La Selva Biological Station, and its association with the lauded Organization for Tropical Studies. In fact, to quote Dr. Bruce Young, a former director of La Selva, in a 1998 videotape entitled "Costa Rica: Science in the Rainforest" (Turner Learning, Inc.), "Every time you pick up one of those picture books about the tropical rainforest, … much of that information came from La Selva." Given the importance of this field station to the conduct of tropical biological research and education, it is fitting that we now have a field guide to its herpetofauna and that of the surrounding Caribbean slope of Costa Rica. It is also fitting that this guide is authored by two herpetologists whose careers have been closely associated with La Selva: Craig Guyer, professor of biology at Auburn University in Alabama, and Maureen A. Donnelly, associate professor of biological sciences at Florida International University in Miami, Florida, who together have more than 40 years of field experience there.

This book joins two others recently published on the herpetofauna of Costa Rica. One is Jay Savage's definitive work on this subject, *The Amphibians and Reptiles of Costa Rica: A Herpetofauna Between Two Continents, Two Seas* (2002). The other is Twan Leenders' *A Guide to Amphibians and Reptiles of Costa Rica* (2001). A tempting question to consider is which book one might place in one of the two bags one can take on a flight to Costa Rica. First, however, let me review the Guyer-Donnelly book.

The main portion of the book consists of a 19-page introduction, an 82-page section on amphibians, a 136-page section on reptiles, and an 11-page section on additional species. Ancillary portions of the book comprise a field data sheet for amphibians and reptiles, a glossary, a literature cited section, and an index.

The introduction deals with a description of the book and its purpose, a discussion of the geography, climate, and vegetation of the station, a history of herpetological research at the station, and discussions of the diversity and conservation of the station's

herpetofauna.

The section on amphibians considers the 49 species recorded from La Selva, including one caecilian, three salamanders, and 45 anurans. Brief discussions of orders and families precede each group of species accounts. The species accounts provide an English vernacular name, the scientific name, other vernacular names, size, range-wide distribution, identifying features, sexual dimorphism, habitat, diet, reproduction, remarks (if pertinent), and a shaded map of the Costa Rican distribution. Dichotomous keys to orders, families, and species are also provided.

The section on reptiles deals with the 89 species known from the station, including five turtles, 25 lizards, 57 snakes, and two crocodilians. The organization of this section is the same as that for the amphibians, including the topics covered in the species accounts, and similar keys are also available.

The section on additional species provides comments on 11 amphibians and nine reptiles known to occur on the Costa Rican Caribbean slope, but not at La Selva. These accounts briefly consider their distribution in the country and general appearance. The glossary consists of 240 terms that may not be familiar to laypeople. The Literature Cited section contains 290 references to papers that appear in the body of the book. An index of 13 pages lists vernacular and scientific names of organisms dealt with in the book.

As is appropriate for a field guide, a series of color plates is divided into two groups, logically one of amphibians (76 plates) and the other of reptiles (131 plates), identified by use of vernacular names (although, for the benefit of herpetologists, it would be nice to have the scientific names accompany the common ones — there is certainly enough room on the page to do so). Illustrations, especially of a photographic nature and in color, are arguably the most important part of a field guide, most critically so if it is intended for laypeople, because it is this part of the field guide that will be examined initially in an attempt to identify what is in hand (or somewhere else, if venomous). So, the color plates in this book can be judged as to how well they allow correct identification by a first-time traveler to Costa Rica with zero herpetological knowledge. By this criterion, for the amphibians, I generally find the photographs arranged two to a page much better able to accomplish this need than are those arranged four to a page. Given that the pages are about 4 $^1/_2 \times 7\ ^1/_4$ inches in size, and that the photographs arranged four to a page have their legends occupying close to half the page width, many of the amphibian photographs are too small to do a very good job of identification. Beyond this, some of these small photographs were cropped too broadly, and therefore show more of the background than of the animal (e.g., plates 3, 8, 26, 31, 32, 34, 36, 39, 43, 48, 52, 61, 67, and 73). Another feature that detracts from the effectiveness of several of these photographs is the presence of human body parts in the frame. This is an unprofessional shorthand approach to dealing with difficult subjects (e.g., specimens of *Eleutherodactylus* that can leap amazing distances).

Some of these same issues also apply to the photographs of reptiles. Another problem most evident with these creatures is poor lighting and backgrounds that are too dark (e.g., plates 80, 87, 92, 98, 100, 105, and several others). Humans get in the picture again, in some cases, to the extent that there is more human than reptile being illustrated (e.g., plates 77, 97, 104, 106, 125, 142, 144, 166, 200, and some others). In response to the question about how well the photographs provided allow for correct identification alone, I have to conclude that, in many cases, they do not do so. As a consequence, the reader will have to resort to using the keys first, then the descriptions and, finally, try to use the photographs to confirm the identification.

The question then arises as to how good a job the keys and descriptions do in identification. For those familiar with the Central American herpetofauna, this job is most difficult when dealing with members of the speciose genera *Eleutherodactylus* (= *Craugastor* or *Eleutherodactylus* currently) among the anurans and *Norops* (= *Anolis* currently) among the lizards. Identifying colubrid snakes can sometimes prove taxing as well, simply because the number of species in the herpetofauna is relatively large. A cursory survey of the keys to these groups indicates that the authors have done an excellent job of constructing them, especially as they are primarily based on features of color and pattern, making them easier for laypeople to use. The descriptions (or identifying features) also do a very good job of securing the identification, once the creature has been "run through the keys." The deficiencies with the photographs could be materially ameliorated in the next edition by going to a two-per-page format and using some reasonable cropping. Some photographs, however, simply need to be replaced with ones that are properly lit and excuse humans as co-subjects.

In these days, when the concern about the decline of biodiversity around the world, but especially in the tropics, is reaching a fever pitch, books like this one can perform a vital function in educating people about this extremely serious problem. In this field guide, one has to look to the sections in the introduction on diversity and conservation to find this message, if it exists. These two sections comprise about five and one-half pages of the book. Although, by its title, one might expect the diversity section to deal with the importance of the diversity of the herpetofauna of La Selva, the discussion actually considers the reasons for the existence of this diversity (geological history, forest structure, and climate) and the sources for additions to the known herpetodiversity. The two-plus page section on conservation, however, does provide a brief, but well-reasoned and insightful discussion of the principal concerns about the persistence of the known herpetofauna of the station into the future. This discussion, moreover, is tantalizing enough to indicate that this subject deserves a full-fledged treatment of its own. To my knowledge, this has yet to be accomplished.

At the beginning of this review, I posed the question as to which of three books on the Costa Rican herpetofauna mentioned should go in the backpack for a trip to the popular destination. Savage's book is the definitive work on this subject and covers the entire country. It, however, is too bulky and heavy to horse around in a backpack. Twan Leenders' book is of an appropriate size and weight and covers the entire country, but not the entire herpetofauna. Guyer and Donnelly's book is also of appropriate size and weight, but covers only the herpetofauna of La Selva in detail and the rest of the Caribbean slope creatures in much less detail, leaving the central mountain spine and the Pacific slope herpetofauna out of consideration. My suggestion is to pack both the Leenders and Guyer-Donnelly books for a trip to any destination in Costa Rica. Another suggestion for a subsequent edition is that the 20 species of Caribbean slope animals be treated in the same detail as those

already recorded for La Selva and simply stipulate that these 20 forms may or may not be found eventually at the research station. This field guide serves several important functions and I am very pleased to see it now available. First, the La Selva Biological Station is host to a prestigious program in tropical biology that brings numerous students, faculty, and researchers to the American tropics from many places around the world, so this guide will be hugely useful as a supplemental textbook in a variety of courses. Second, the country of Costa Rica is a popular ecotourist destination, so this guide will be of interest to those tourists who wish to learn more about these two groups of vertebrates while "in country." Finally, Mesoamerica is an important "biodiversity hotspot" and, as such, it is important that the word get out as broadly as possible about the immense importance of the biological resources of this region. This book will assist in all these ways.

PUBLICATIONS RECEIVED

Encyklopedia Współczesnych Płazów i Gadów, by Piotr Sura. 2005. Wydawnictwo Fundacja, Nowy Sacz, Poland (www.wydawnictwo.sacz.com.pl). 544 pp. Hardcover. 85.00 zl (approx. US $27.00). ISBN 83-88887-60-2.

This Polish language encyclopedia of amphibians and reptiles is organized alphabetically by Polish vernacular names. The first part of the book, printed on glossy paper, is lavishly illustrated with hundreds of color photographs, maps (by Family), and line drawings. In addition to entries for individual taxa, there are accounts dealing with biological topics (e.g., hemipenis, mimicry), and even biographical entries (e.g., Cope, Mertens). Among the animals illustrated are some rarities and nearly all photos are of high quality. The second part of the book, beginning on page 273 is a 266-page systematic listing of amphibians and reptiles of the world. All currently recognized species are listed, along with their authors and dates of description. The book is rounded out by a literature section with more than 150 references, mostly covering higher order groups or faunal regions.

The Diversity of the Dumbara Mountains (The Knuckles Massif, Sri Lanka): With Special Reference to its Herpetofauna (Including Papers on Sri Lankan Herpetology), edited by Anslem de Silva. 2005. Lyriocephalus, Journal of the Amphibia and Reptile Research Organization of Sri Lanka (ARROS), Volume 6, Special Issue, available from A. de Silva, 15/1 Dolosbage Road, Gampola (CP), Sri Lanka. 382 pp. Softbound. US $40.00 (including airmail delivery; checks to K.A.L. de Silva). ISSN 1391-0833.

This special issue of the Sri Lankan journal *Lyriocephalus* contains 40 individual papers, the majority of which deal with aspects of the herpetology of the Knuckles Massif, a biologically diverse, forested range in Sri Lanka. The herpetological papers deal chiefly with different aspects of natural history, ecology, and parasitology, with an emphasis on lizards. Among the genera discussed are the endemic agamids *Lyriocephalus, Cophotis,* and *Ceratophora*, the skinks *Chalcidoseps*, *Nessia*, and *Lankascicnus*, *Cyrtodactylus* geckos, and uropeltid snakes. In addition, there are papers on the geology, climate, vegetation, malacology, archaeology, and ethnobiology of the Knuckles, and a 217-entry bibliography of publications devoted to the area. Another nine papers are general herpetological contributions relating to other aspects of Sri Lankan reptiles. The volume also includes a cumulative index to volumes 1–5 (1994–2004) of *Lyriocephalus*. This issue includes 17 color plates depicting many of the species of reptiles and amphibians from the Knuckles and otherwise illustrating the individual paper contributions. This volume will be a welcome addition to the libraries of those interested in the South Asian herpetofauna or tropical biodiversity in general.

Proceedings of the 3rd International Symposium on *Emys orbicularis*, edited by Uwe Fritz and Peter Havas. 2004. Biologia, Section Zoology, Volume 59, Supplement 14 (Slovak Academic Press, Ltd.; www.sappress.sk). iv + 209 pp. Softbound. ISSN 1335-6380.

This volume presents the proceedings of a symposium on the European Pond Turtle held in Kosice, Slovak Republic in 2002. The contributions are divided into the categories "Distribution and Habitat," "Natural History," and "Conservation and Management" and include data on populations from throughout the range of the species, from Spain and Portugal to Russia and Turkey. The information presented reveals a diversity of locality-specific ecological, demographic, and reproductive aspects of the biology of this endangered turtle across its broad distribution. Among the topics dealt with in individual papers are haplotype diversity in Germany, coexistence with *Mauremys leprosa* in Portgugal, survivorship in Poland, home range in France, Pleistocene, Holocene and historical records from the Czech Republic, and the effects of recreational fishing on *Emys* in France. The proceedings as a whole (presented entirely in English) offer the reader a well-rounded portrait of the biology of Europe's most important freshwater chelonian. This supplemental volume to the Slovak journal *Biologia* will be of interest to all those working on freshwater turtles, the European herpetofauna, or reptilian biology and conservation.

Snake, by Drake Stutesman. 2005. Reaktion Books Ltd., London (distributed in the USA and Canada by University of Chicago Press, Chicago, Illinois; www.press.uchicago.edu). 224 pp. Softcover. US $19.95. ISBN 1-86189-239-X.

This compact and well-illustrated book traces the symbolism of snakes through the ages. After a brief introduction to snakes for the novice, the book outlines the role and meaning of snakes in creation myths, their symbolism as creators, saviors, and demons, and the religious and symbolic significance of snake handling. The examples discussed and illustrated derive from a diversity of sources, from Paleolithic cultures to ancient Egypt and Mesoamerica, to Hindu traditions, to Greece and Rome, to modern Haiti and Kentucky. Another chapter discusses venomous snakes, venom, and snakebite beliefs and remedies, and two short chapters discuss the "Edible Snake" and "Pet Snake," emphasizing the meaning behind these respective uses of snakes by humans. A final chapter, "Vogue Snake," examines snakes in art,

fashion, film, and popular culture. The book closes with a timeline of snakes, a bibliography, a series of recipes involving snakes, a list of herpetological associations and websites, and an index. This idiosyncratic volume is difficult to describe, but is full of fascinating information, much of which will be new to most herpetologists. The illustrations, many in color, are especially intriguing, although purists will be disappointed that many classic herpetological plates are reproduced without reference to the works in which they appeared.

Ecological Consequences of Artificial Night Lighting, edited by Catherine Rich and Travis Longcore. 2006. Island Press, 1718 Connecticut Avenue, NW, Suite 300, Washington, DC 20009. xx + 458 pp. Softcover. US $29.95 (Cloth: $65.00). ISBN 1-55963-129-5 (Cloth: 1-55963-128-7).

This edited volume considers the effects of artificial light on all major groups of vertebrates, as well as insects, freshwater invertebrates, and plants. Four chapters totaling 114 pages, or one fourth of the book, are devoted to amphibians and reptiles. A chapter by Michael Salmon documents how artificial light impacts sea turtle nest site selection and orientation of hatchlings and discusses methods of light mitigation and comprehensive light management plans in place in parts of Florida. Gad Perry and Robert N. Fisher consider the effects of lights on lizards and snakes, which include both positive (enhanced or extended foraging) and negative (increased predation risk and decreased foraging success) aspects. They also review studies that indicate that photoperiod and/or light intensity may influence squamate behavior and that artificial light may affect interspecific interactions. Bryant W. Buchanan evaluates the effects of artificial night lighting on anuran aggregation, foraging, reproductive, antipredator, and photoperiodic behavior, egg and larval development, and tadpole behavior. In addition he outlines the consequences of spectral composition and illumination intensity on the visual system and on behavior. A final herpetological chapter by Sharon E. Wise and Buchanan deals with the behavioral and physiological responses of salamanders to artificial light including changes in territorial behavior, endocrine function, metabolic rates, activity, orientation, and homing. This book makes an important contribution to the understanding of the growing problem of light pollution and will be of interest to a broad range of herpetologists and other biologists, especially those whose organisms occupy urban and suburban habitats or other areas that experience significant artificial illumination.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address). To submit a manuscript to ***HR***, please consult the SSAR webpage at:

<http://www.ssarherps.org/pages/HRinfo.php>

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution or Natural History notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order form will be sent prior to publication. These are also available upon request from the Editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR Treasurer (Dr. Theodora Pinou; contact information below) or from the SSAR web page (http://www.ssarherps.org/pdf/Adrates.pdf).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at WCSU, Department of Biology, 181 White Street, Danbury, CT 06810, USA. Periodicals postage paid at Danbury, CT 06810 and at additional mailing offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Breck Bartholomew, PO Box 58517, Salt Lake City, UT 84158, USA. Please notify Breck Bartholomew, SSAR Publications Secretary (contact information below), regarding missing or damaged issues.

SSAR Publications

SSAR publishes seven different series: *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Contributions to Herpetology, Herpetological Circulars, Herpetological Conservation*, and the *Catalogue of American Amphibians and Reptiles* (see below for CAAR details). SSAR members receive pre-publication discounts on all *Facsimiles* and *Circulars* and on volumes in the *Contributions* and *Herpetological Conservation* series. A complete pricelist of Society publications is available at: <http://www.herplit.com/SSAR/>

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 760		US $460
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$6
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$6
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 760	$320

To order: make checks payable to "SSAR" and mail to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, Utah 84158, USA (fax 801/453-0489). e-mail: ssar@herplit.com.

RECENT POPULATION CHANGES

HERPETOLOGICAL HUSBANDRY

identify individuals in a population. For example, with 2–4 injection sites on our geckos (i.e., the near-transparent undersides of knee and elbow joints), a large number of unique color combinations was possible given the availability of five readily distinguishable VIE colors, and the experimenter's own injection-pattern variability. The greater effort and higher cost of elastomer, relative to the other surface-marking methods we tested, are outweighed by the longer retention time of the VIE.

Acknowledgements.—We thank R. McCord for anecdotal inspiration and B. Joslin for advice on capture locations and capture tactics. We also thank S. Nolan, M. Sessions, and B. Adelson for field companionship and assistance and K. Wright for loan of the heat lamp. We thank G. Rodda and an anonymous reviewer for their comments. Geckos were captured under Arizona Game and Fish Department collecting permit SP636712, issued to KEB. Geckos were marked under University of Arizona IACUC permit 03–023.

The Evolution of Three Deviations from the Biphasic Anuran Life Cycle: Alternatives to Selection

RONALD ALTIG

e-mail: RAltig@biology.msstate.edu

and

BRIAN I. CROTHER
Department of Biological Sciences, Southeastern Louisiana University, Hammond, Louisiana 70402, USA
e-mail: bcrother@selu.edu

The origins of the diversity of breeding modes in anurans beg for more focused hypotheses, but no suggestion for the evolution of any grade of endotrophy (= development without a free-living, feeding tadpole *sensu* Altig and Johnston 1989) has received rigorous testing (e.g., Salthe and Duellman 1973). Direct development occurs in at least nine anuran families (Thibaudeau and Altig 1999), and other grades of endotrophy add to the list of deviations from the classical biphasic anuran life cycle. Selection has been proposed as the process by which these various reproductive modes arose (e.g., Downie 1993; Magnusson and Hero 1991). The prevalence of these breeding patterns in species rich, tropical assemblages has presumably been caused by selection for escaping crowded (i.e., competitors) and hostile (i.e., predators and abiotic factors) aquatic habitats (e.g., Duellman 1978). Yet, hundreds of species reproduce in aquatic sites in many habitats despite experiencing low and sporadic recruitment (e.g., Greenberg and Tanner 2005). Accordingly, we should not assume that any of these reproductive deviations afford vastly superior recruitment over the typical life cycle (e.g., Roberts 1994; Rödel et al. 2002), especially when egg survival is the only criterion that is commonly reported.

In the near absence of prevailing hypotheses that address the evolution of these various developmental modes (see Callery et al. 2001), we discuss an alternative to selection. We argue for a nonhierarchical approach in a system that suggests a hierarchical structure. Adhering to a hierarchical system oversimplifies a complicated process and inhibits finding a viable solution. Many broad questions need to be answered, and only after the collection of pertinent specimens and data can we eventually revisit the larger question of the evolution of divergent reproductive modes. We discuss three reproductive grades as examples that we propose have arisen independently by different genetic mechanisms, usually multiple times: arboreal eggs, nidicolous larvae (= variously modified, nonfeeding tadpoles usually confined to a "nest"), and direct developers (= froglet hatches from egg jellies). With an understanding of developmental biology increasing daily (e.g., Gilbert 2001; Raff 1996; Robert et al. 2001), discussions of competing hypotheses should help direct future studies.

We argue that those taxa that lay arboreal eggs over water and develop normally as tadpoles achieved those capabilities via se-

lective forces that coordinated two primary subjects: initially the calling behaviors of males and subsequently the ovipositional activities of females. If we assume that a male calling from the ground near a breeding site and laying eggs with a female in the adjacent water is the ancestral state, then males calling from elevated sites might be a first step in the evolution of arboreal oviposition. This move by the male was likely stimulated by selection for better spatial and acoustic resolution for mate choice in multispecies choruses. At least three variations in female activities can be recognized in what may be a logical progression: (1) a female goes to a male on an elevated perch and the amplexed pair returns to the water to oviposit (e.g., *Hyla avivoca* and *H. cinerea*; the female is not required to collect cloacal water for egg hydration), (2) a female goes to an elevated male and the amplexed pair returns to the water so that the female can gather cloacal water to hydrate eggs before returning to an elevated site for oviposition (e.g., *Pachymedusa dacnicolor*; Bagnara et al. 1986), and (3) a female goes to an elevated male and oviposits at an arboreal site (e.g., several dendrobatids and leptodactylids). In the third case, the female's actions prior to traveling to the male and/or the characteristics of the eggs must have evolved relative to the other two cases. In the absence of prior changes in eggs or development, we assert that none of these situations is a precursor to direct development. Analyses by Roberts (1994) showed that arboreal eggs evolved independently at least 10 times in Anura, that this mode evolved within lineages having both aquatic and terrestrial oviposition sites, and that it sometimes reverted to the presumed ancestral state. The hypothesis that this mode evolved in response to intense predation in aquatic systems was not supported (Roberts 1994).

We suggest that at least minor changes in egg energetics, egg jelly, and developmental trajectories must precede ovipositional changes for a pathway to lead to a total escape from the aquatic system. Developmental changes indicative of increased yolk density (e.g., Chipman et al. 1999) occur in numerous taxa, but we have little understanding of the relationships among ovum sizes, yolk gradients, or energy contents (Thibaudeau and Altig 1999; see Komoroski and Congdon 2001). Larger eggs result in larger larvae that maintain their size and growth advantages throughout their ontogeny (e.g., Dziminski and Alford 2005), but we have little idea which characteristics of a large egg promote these responses. A proportional increase in energy content is presumed, but this, and variations in other kinds of maternal provisioning, need verification among taxa representing diverse breeding modes.

Is the embryology of direct development more expensive than exotrophic development and is the increase in yolk in large, direct-developing eggs intended for embryological or posthatching development? Physical factors associated with being in air, energy sources and RNA transcripts provided by the mother during vitellogenesis, and provisioning of posthatchlings that are sometimes very small (e.g., hatchling *Sooglossus gardineri* are ca. 1 mm SVL; pers. observ.) are important factors to consider. Knowledge of the kinds and amounts of maternal provisioning of eggs from species that represent a number of reproductive modes are needed before we can start to understand the energetics of development. Changes in breeding mode likely occur only when a number of factors occur collaboratively, if not synergistically. For example, we reject the idea that arboreal foam nests involving numerous small eggs could be a precursor to direct development (Bossyut and Milinkovitch 2000). In this case, the eggs are out of water, but none of the other factors we consider required for the transition to direct development is present. This disagreement illustrates that we do not know enough about the probable sequence or many interactions of adults, ova, and development underlying such a transition in reproductive mode.

We suggest that the multiple occurrences of nidicoly represent independent truncations of normal development, but the specific benefits of these developmental modes remain unclear. Although nidicolous species likely share some of the presumed fitness benefits of arboreal eggs or direct development, we suggest that nidicoly has no developmental, genetic, or evolutionary associations with the other two modes. The details of a nidicolous ontogeny surely proceeds by patterns similar to typical larvae, whereas direct development involves a highly modified developmental pattern that does not involve developmental truncations, at least of similar kinds; nidicolous larvae likely are paedomorphic products of more modest regulatory changes (see below) while not violating metamorphic constraints required to recover a frog morphotype. If we knew which characters are affected to what degree and in what sequence or associations (see Thibaudeau and Altig 1999), then we would know the primacy of developmental occurrences, their developmental integration, and thus the relative degree of the truncation.

Direct development is different from the development of exotrophic tadpoles in a biphasic life cycle in many ways beyond the obvious developmental differences and the retention of a subtle, thyroid-based metamorphosis (Callery and Elinson 2000). Such differences include a precocial neural tube anatomy (Schlosser 2003), a different mode of abdominal wall formation (Elinson and Fang 1998), limb development in the absence of an apical ectodermal ridge (Richardson et al. 1998), and at least three types of tail development (i.e., small tails, with small fins, flexed ventrally, some myobatrachids (M. Anstis, pers. comm.); larger tails with large fins, flexed ventrally, some microhylids (pers. observ.); and larger tails with large fins, flexed laterally, some leptodactylids (Townsend and Stewart 1985). Admittedly our perspectives are myopic because most data are based on one species of *Eleutherodactylus*.

The unusual embryology (Elinson and Del Pino 1985), development (Wassersug and Duellman 1984), and unique bell gills of amphignathodontids (*sensu* Frost et al. 2006), although based largely on studies of one species of *Gastrotheca*, represent perhaps another form of endotrophy besides those discussed above. In no other genus is there a scattering of froglet-producing and tadpole-producing species. Wassersug and Duellman's (1984) suggestion that tadpoles are produced by some form of truncation of the froglet-producing program is debatable, but at least the reproductive diversity in this genus suggests that a variety of developmental programs can be switched rather easily, or often, among members of some lineages.

The primary alternative hypothesis for the origin of direct development is: although unknown selective pressures acted on prerequisites (e.g., ovum characteristics), the actual originations of direct development did not involve selection. The presumed switch from exotrophic tadpoles to direct development most likely occurred via major regulatory gene(s) deep within the developmen-

tal cascade, and the wide-ranging occurrences of direct development among families suggests that the genomes of all frogs contain the basic components of this developmental program. The origin of this novel embryogenesis must have been associated with a release from the developmental bias or constraint that governed the biphasic life cycle. There is no need to invoke gradual change via small multiple steps, each selected along the way. Instead there could have been a single, radical developmental change that bypassed the typical larval stage. Concomitant with that change, an independently evolved novel egg phenotype allowed the first direct developer to succeed, and selection would operate after the fact to maintain the novel embryogenesis. The release from the developmental bias can be viewed simply as the removal of barriers to developmental experimentation in contrast to some directional process. From this perspective, we should expect to find the various novel phenotypes that have subsequently evolved.

Did these genetic programs evolve in salientian (*sensu* Cannatella and Hillis 1993) life histories or are they even older? Direct development occurs in salamanders and caecilians, although the actual ramifications of it vary because of developmental patterns unique to each group. Drastic changes in structural genes were likely not required, thus the end product only allowed those taxa involved to expand into new reproductive niches. Viewing the morphologies of the three developmental deviations described above in a series from least-to-most modified (assuming we had the data to do this), would show the various potentials of developmental genetics but no corresponding phylogenetic affinities among grades. None of the three grades seemingly provides the requisite morphologies from which any of the other two could be derived.

Our proposal was generated from an observation and a presumption. Direct development has evolved numerous times (e.g., Marmayou et al. 2000 for a specific example) with many commonalities and differences across taxa. Conversely, the multiple occurrences of this developmental pattern based on successfully coordinated point mutations seem less plausible than being caused by basal regulatory changes (see above). The alternative, which cannot be resolved because of our paltry database, that the presumed similarities in morphology, behavior, and physiology of direct developers are produced by some unknown number of convergent genetic manipulations, seems equally unlikely because of the complexity of the many developmental changes.

If anuran development is capable of switching from exotrophic to endotrophic development by a yet unknown mechanism, perhaps the reverse occurs. Could the morphological oddities of exotrophic microhylid tadpoles (e.g., Wassersug 1989) be an example of an exotrophic tadpole with endotrophy in its ancestry? Thus, do all tadpoles have the same phylo-developmental history? Such initially outlandish scenarios gain credence in light of discussions (e.g., Chippindale et al. 2004; Mueller et al. 2004) that suggest developmental switches within lineages. Even though these particular cases involve salamanders wherein the direct developers are not nearly as divergent from typical cases as occurs in frogs, the genetic bases for such modifications are at least present in the genome of amphibians.

Other research fields may offer insights into the developmental patterns of direct development and its origins. For example, an exotrophic larva is immunocompetent, but it must reduce its immunocompetence by eradicating certain larval lymphocytes to avoid autoimmune responses when novel proteins appear at metamorphosis (Rollins-Smith 1998; Ruben et al. 1989). Direct development may be a means of avoiding metamorphic antigens without the hazards of immunosuppression. Model-based studies of metamorphic immunosuppression do not include information on direct developers. Also, if direct development involves upregulation of gene expressions, the energetic costs (Wagner 2005) may be an influential factor. Next, Galis et al. (2003) suggested that limb regeneration occurs readily in amphibians but not other tetrapods because the late development of the limbs removes a constraint of being associated with the development of the main body axis. If true, the patterns of limb regeneration (see Alvarado 2000; Brockes et al. 2001) in direct developers, whose limbs develop concurrently with the body axis, may more closely resemble the developmental patterns of reptiles. Last, certain marine invertebrates with varied developmental patterns have been studied in more detail than amphibians. For example, Strathman et al. (2002) noted that embryos that experience parental care develop more slowly than, in their case, free-living, planktonic forms. More informatively, these researchers suggested that slower development may permit compensation for less maternal investment of rate-limiting materials to the eggs and correction of developmental errors. This is the reverse of the common assumption (e.g., Dziminski and Alford 2005) that the large eggs of direct developers are better provisioned, and parental care was suggested as the equalizing factor.

The typically low species diversity among direct-developing lineages suggests that these developmental patterns are not entirely successful. The extant taxa could be the surviving members of larger assemblages in the past, but the fact that ca. 44% of the direct-developing taxa are not monophyletic with other direct-developing lineages suggests that selection did not produce the loss of the aquatic tadpole stage. Selection undoubtedly has maintained these lineages, but we argued above that the required embryological changes were not borne from selective forces per se. Species-rich exceptions may involve undetected developmental improvements over the clades with fewer species, or speciation in these lineages perhaps is not influenced by the success of their developmental modes.

Examples from the rapidly growing evolutionary and genetic literature give us a viewpoint from which to discuss new hypotheses. We do not propose actual mechanisms that may have been instrumental in the originations of any of the three developmental grades discussed here, but it is obvious that we are gaining access to relevant mechanisms that appear to give natural selection much more latitude to operate on a faster time scale. Arthur (2002) proposed the "biased embryo" hypothesis (i.e., the tendency for developmental systems to produce variant trajectories in some directions more readily than others) with four organismal levels of reprogramming that act as partners with selection. Fondon and Garner (2004) proposed that gene-associated tandem repeat expansions and contractions in *Hox*-family genes could promote rapid morphological change. Building on these studies, Ruden et al. (2005) hypothesized that stressors could be the trigger. Dehydration and thus ion balance, gas exchange, immunological factors, and changes in egg provisioning are possible options for stressors in the cases discussed here. The *Bmp*4 gene (Abzhanov et al. 2004; Albertson et al. 2005) is an interesting candidate for developmental adjustments in both direct-developing and typical amphibian

larvae.

Evolutionary and developmental geneticists should be aware that natural experiments in amphibian developmental patterns are awaiting explanations; there are frogs other than *Xenopus* that are strange in more interesting ways.

Acknowledgments.—The contents and readability of this paper were enhanced by discussions with several colleagues and both the identified and unidentified reviewers.

Since the 1970s the Northern Leopard Frog (*Rana pipiens*) has experienced significant declines in the western United States and Canada (Clarkson and Rorabough 1989; Corn and Fogelman 1984; Corn et al.1989; Hayes and Jennings 1986; Leonard et al. 1999; Orchard 1992; Roberts 1992; Wagner 1997). In western Montana, Northern Leopard Frogs were not detected at 31 historical sites and 1,324 non-historical sites, about half of which were considered suitable for *R. pipiens*, surveyed between 1997 and 2002 (Werner 2003). During these surveys, two extant, but previously unknown populations, known as the Foy Lakes and Meadow Chain-of-Lakes populations, were found (Fig. 1, Werner 2003). In 2002 to 2005, we initiated new, more intensive surveys of these two populations. Herein, we summarize their recent history (1995-2001), and from 2002–2005 surveys, we address their geographic range, approximate size, and level of reproduction.

MATERIALS AND METHODS

The Foy Lakes population is located in Flathead County, Montana, 2.2 km W of Kalispell, on a chain of four interconnected lakes (Fig. 1). The area covers about 7 km^2 and is located mostly on private lands with housing developments around some lakes. The presence of Northern Leopard Frogs at Foy Lakes was first made known to us in 1997. The closest historical record for this frog is at Smith Lake National Wildlife Refuge (NWR), approximately 8 km to the southwest in the same drainage, but the last observation of the frog at the refuge was in 1974. Surveys since 1993 failed to find frogs at the Smith Lake NWR or other nearby sites (Werner 2003).

The Meadow Chain-of-Lakes population (hereafter, "Chain-of-Lakes") is located 2.5 km S of Eureka in Lincoln County, Montana (Fig. 2). Chain-of-Lakes is situated on a timbered plateau ca. 125 m above the Tobacco River Valley. The area covers ca. 64 km^2 with numerous interconnecting lakes, ponds and wetlands except during dry years when smaller ponds and interconnecting waterways dry up. Historically, Northern Leopard Frogs were known from several lakes in the Tobacco River valley 10 km to the north, although no frogs were found at those sites in recent surveys (Werner 2003). We first observed Northern Leopard Frogs at Chain-of-Lakes in 1997.

We gathered background information prior to 2002 for the Foy Lakes and Chain-of-Lakes areas from unpublished surveys done by state and federal agencies, by the authors, or by other individuals. Most reports were of sporadic surveys made during the spring or summer, usually with an objective to determine species richness, and were conducted by individuals having a wide range of experience. Hence, direct comparisons to the 2002 to 2005 surveys were not possible, but the data are included here because they provide a historical record and point of reference for discussion.

Beginning in 2002, our goal was to survey all marshes, ponds, and lakes within the Foy Lakes and Chain-of-Lakes areas for 3–4

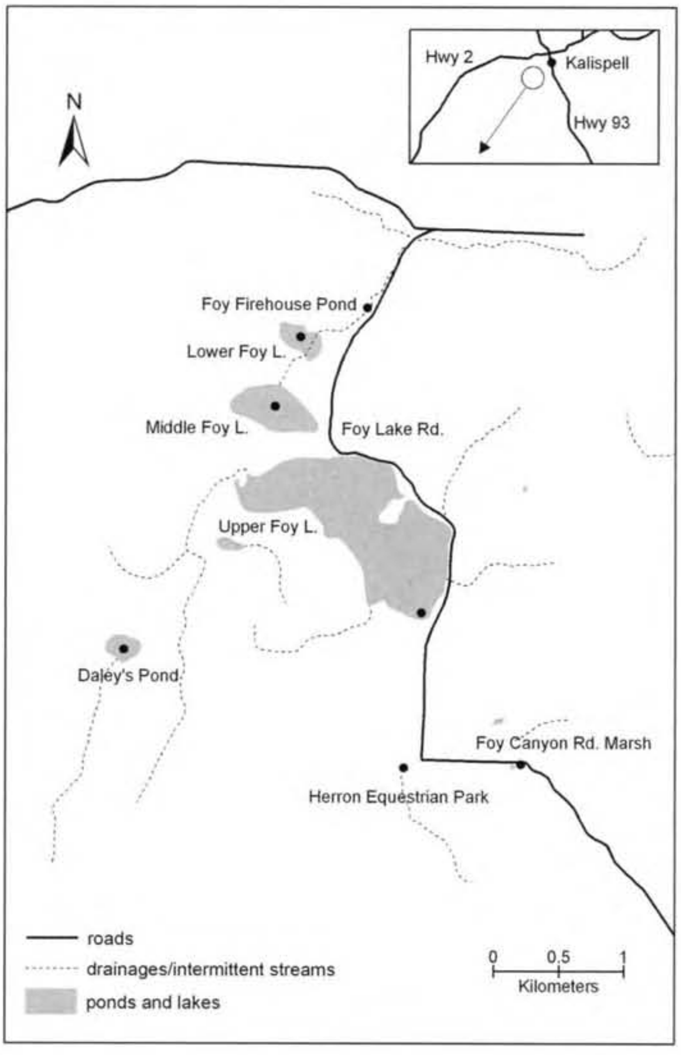

FIG. 1. Foy Lakes survey area in western Montana, USA.

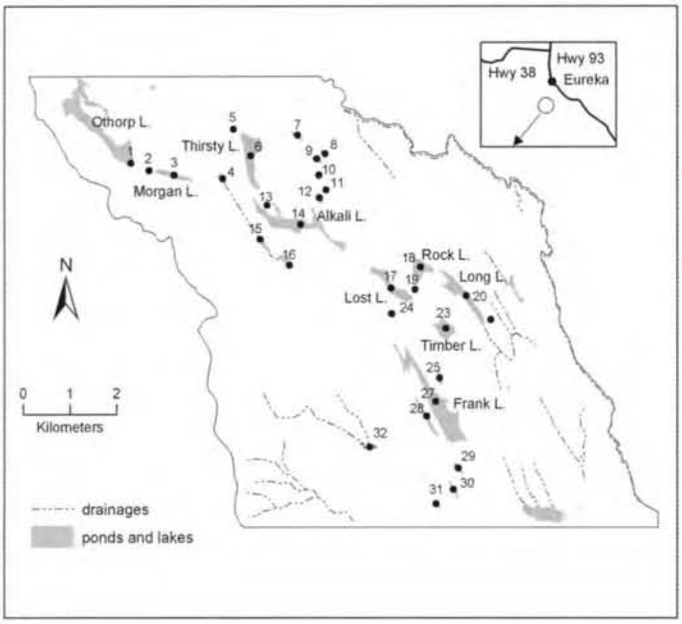

FIG. 2. Meadow Chain-of-Lakes survey area, Murphy Lake District, Kootenai National Forest, Montana, USA. Numbers correspond to survey sites listed in Table 4.

consecutive years. Within both areas, we designated each wetland type as a separate site. One to six people (usually two to four) undertook visual encounter surveys for 15 min to 3 h per site using methods described by Thoms et al. (1997) and in accord with the schedule below. For marshes, ponds, and small lakes, we surveyed the entire perimeter and dipnetted in the shallow water zone at regular intervals of about 3 m. The physical size of larger lakes and private ownership of shorelines in some instances, required that we be selective in choosing what areas to survey around larger lakes. Based on our previous experience in this area, we concluded that shorelines with steep, abrupt edges or rocky cliffs, and shorelines of open sand and gravel with no emergent vegetation, were not suitable leopard frog habitat, and hence we did not survey them. In the Foy Lakes area, about 50% of the total shoreline making up the Upper, Middle and Lower Foy lakes was not surveyed, with about 90% of the un-surveyed area being regarded as non-suitable habitat, and about 10% was likely suitable habitat but not accessible due to private ownership. In the Chain-of-Lakes area, about 15% of the large lake shoreline was not surveyed, 98% of the un-surveyed area was regarded as non-suitable habitat, and 2% was suitable habitat but inaccessible due to private ownership. Larger lakes with only a portion of their shoreline surveyed were noted. Surveys at larger lakes were conducted in the same manner as ponds and small lakes except for a more sporadic pattern of dipnetting in near-shore zones.

In 2002, we attempted to survey all sites three times, once in early spring during breeding, a second time in late June/early July when tadpoles should have been present, and again in late July/early August when new metamorphs should have been present. However, some smaller marshes and ponds dried up by June or July and all three surveys could not be completed. In 2003 and 2004, we surveyed the same sites unless they were dry, once in late June/early July and again in late July/early August. In 2005, we surveyed in late June only those sites where frogs had been seen previously. Marshes and ponds that dried each year were recorded. During each survey, we assumed frogs were counted only once, but this was not verified because frogs were not captured or marked. Consequently, we did not attempt to estimate population size.

In 2002, we also conducted auditory surveys at wetlands where Northern Leopard Frogs had been sighted in previous years' surveys. We did auditory surveys at night, playing a tape recording of Northern Leopard Frog calls while walking slowly around the periphery of ponds, or paddling a canoe slowly along the edge of larger lakes.

RESULTS

Foy Lakes Population.—In 14 surveys conducted between 1997 and 2001, observers reported Northern Leopard Frogs at five Foy Lakes sites (Table 1, Fig. 1). These early surveys reported only adults at four sites, but at the fifth site, Lower Foy Lake, 111 juveniles and 154 adults were seen in 1998, and 10 egg masses were observed during spring 2001. In a late summer survey, however, no tadpoles or metamorphs were seen at or near the oviposition site, and in 2002 no young frogs were observed, implying that the reproductive effort may have failed. The authors of these early reports distinguished juveniles from adults based on relative body size, but no body lengths were measured.

During 2002 to 2005, we conducted 39 surveys at seven sites involving 46 person-hrs of observation (Table 2). We conducted only limited surveys at three, Daley's Pond, Foy Canyon Rd marsh, and Herron Equestrian Park because they either dried up by early spring or in the case of Herron Equestrian Park, the wetland was altered as part of a renovation project (Table 2). Overall, we saw Northern Leopard Frogs at three sites (Foy Firehouse Pond, Lower Foy Lake, and Middle Foy Lake) with 0 to 12 frogs being observed per survey. Over all four years, the mean detection rate was 1.2 frogs per person-hr. We compared data among years at the two sites with the highest detection rates (Foy Firehouse Pond and Lower Foy Lake, Table 3). June data were chosen because they provided the most uniform survey conditions over all four years. Averaged together, the detection rate (frogs/person-hr) at these two sites was 2.3 in 2002, 5.3 in 2003, 2.0 in 2004, and 1.0 in 2005 with an overall mean of 3.1. Notable among all surveys was our August 2004 sighting of 3 metamorphs and 1 adult at Lower Foy Lake, and 4 metamorphs at Foy Firehouse Pond, indicating at least one successful egg-laying event. In 2005, 7 more metamorphs were seen at Lower Foy Lake, again indicating at least one successful egg-laying event. We saw no frogs at Herron Equestrian Park or Upper Foy Lake where adults were reported in 1997 and 1998 surveys.

Chain-of-Lakes Population.—In surveys conducted between 1995 and 2001, Northern Leopard frogs were seen at six sites (Table 4). Successful reproduction is supported at Chain-of-Lakes prior to 2002 as indicated by reports of juveniles at Leopard Ponds in 1995, 1997, and 1998, tadpoles at Rock Lake in 1996, juveniles at Summerville Lake in 1996, and juveniles at Timber Lake in 2000. Again, observers distinguished juveniles from adults based on relative body size, but no body measurements were actually made. An egg mass was seen at Leopard Ponds in 1997, but it could have been either from a Columbia Spotted Frog (*Rana luteiventris*) or

the Northern Leopard Frog. Observers reported adult frogs at two other sites, Frank Lake in 1996 and 1998, and Heather Pond in 1996, 1998, and 1999. All six sites are within a 4 km^2 area.

From 2002 to 2005, we conducted 168 surveys at 30 sites involving 724 person-hrs of observation. Limited surveys at 7 of 30 sites were conducted due to wetland drying, or on a few occasions, temporarily being unable to access a wetland on private land (Table 5). During the 2002 and 2003 surveys, we saw only 1 or 2 adult frogs per survey at Hayes Pond, Morgan Lake, Othorp Lake, Frank Lake, Summerville Lake, and Timber Lake, but no frogs at these sites during the 2004 and 2005 surveys (Table 5). The first three sites, Hayes Pond, Morgan and Othorp Lakes had not been surveyed prior to 2002; the last three sites were known to have frogs present before 2002 (Table 4). Also, we did not see frogs at Rock Lake or Heather Pond where they had been reported prior to 2002. We saw 0.02 frogs/person-hr averaged over all four years. When considering only the June 2002 to 2005 surveys at the two sites with the highest detection rates (Morgan Lake and Timber Lake), and combining the results, we saw detection rates ranging from 0 to 0.4 frogs/person-hr (Table 3). We saw no eggs, tadpoles, or metamorphs at any of the 30 sites during the 2002 to 2005 surveys.

Discussion

Despite using similar survey methods, it is difficult to compare

Table 4. Summary of 1995–2001 surveys conducted in the Meadow Chain-of-Lakes area, Murphy Lake District, Kootenai National Forest, Montana, USA (UTM coordinates for NAD 83). Site numbers correspond to those shown in Fig. 2. "—" indicates site was not surveyed until 2002. E? = egg mass present but uncertain whether it was from *R. pipiens* or *R. luteiventris*; T = Tadpoles; J = Juveniles; A = Adults.

[a] Large lake where only a portion of the shoreline was surveyed; see text for explanation.
[b] Number of surveys limited due to wetland drying up, or temporarily unable to gain access from private owner at the time of surveying.

the Foy Lakes and Chain-of-Lakes populations directly. Chain-of-Lakes covers nine times the area of Foy Lakes and habitat differs between these locations. Further, we conducted 168 surveys in 724 hours at 30 Chain-of-Lakes sites, and only 39 surveys in 46 hours at seven Foy Lakes sites. Nevertheless, frogs were encountered more frequently at Foy Lakes than Chain-of-Lakes, but detection rates were relatively low at either location.

The existing Foy Lakes population appears to be centered at Lower Foy Lake and Foy Firehouse Pond (Fig. 1). June data at these two sites showed more frogs were present in 2003 (21) than in other years (7 in 2002, 4 in 2004, and 2 in 2005; Table 3). The most significant observation may be the presence of metamorphs in both 2004 and 2005. The last time eggs were observed at either site was at Lower Foy Lake in spring 2001, but no metamorphs were seen afterwards. The last year juveniles were observed at Lower Foy Lake was 1998. Since only a few metamorphs were seen in 2004 (3) and 2005 (7), it is possible that only a single egg-laying event occurred each year. The distance between Lower Foy Lake and Foy Firehouse Pond is 0.4 km so it is possible that metamorphs at both locations originated from the same oviposition site. Given the four year survey period and extensive surveys covering 90% or more of suitable habitat, the Foy Lakes population within the wetlands appears to be very small, consisting mostly of adults, and showing limited reproduction from 2002 to 2005. The results from all or any one survey provide only a partial picture of the total population present at that time, and given unknowns regarding dispersal, the total size and age distribution of the Foy Lakes population remains unknown.

At Chain-of-Lakes, our original impression was that the existing population was centered at Timber Lake because all previous

observations had come from that area (Fig. 2). However, our 2002 and 2003 surveys showed frogs present in the northwest corner at Othorp and Morgan Lakes. Further evidence for a more widespread distribution came in 2005 when 3 adult frogs and possibly tadpoles (they could have been Columbia Spotted Frog) were seen 8 km to the west of Othorp Lake, at Phills Lake, which was out of our survey area. A previous survey at Phills Lake in 2001 was negative for Northern Leopard Frogs. The current situation at Chain-of-Lakes is difficult to assess. Certain indicators of population success seem to show a downward decline (no evidence of reproduction at any sites during the 2002 to 2005 surveys, a total absence of frogs in 2004 and 2005 at sites they had been seen at in 2002, 2003, or earlier, and overall the low number of frogs seen). Still, there are wetlands surrounding Chain-of-Lakes that could be harboring frogs (e.g., Phills Lake). Additional surveys over a larger areas is warranted before conclusions can be drawn regarding the status of the Northern leopard Frog at Chain-of-Lakes.

There is evidence that the chytrid fungus (*Batrachochytrium dendrobatidis*) is a factor in the decline of some amphibians in the western United States (Bradley et al. 2002; Carey et al. 1999, 2003; Davidson et al. 2003; Muths et al. 2003; Ouellet et al. 2005). One of six animals from Foy Lakes tested positive for chytrid fungus in 2004 (PCR assay; Pisces Molecular LLC, 2200 Central Avenue, Suite F, Boulder, Colorado 80301-2841, USA). No animals have been tested at Chain-of-Lakes. Given the small number of frogs observed and their fragmented distribution, it is possible that the Foy Lakes and Chain-of-Lakes populations may be remnants of larger populations that have succumbed to fungal infections. Given the close proximity of Foy Lakes to the Smith Lake NWR, and the latter's extensive wetlands and historical records, re-surveys and fungal testing at the refuge would seem advisable. Northern Leopard Frogs may have been overlooked in earlier surveys because of small numbers. Similarly, re-surveys of sites in the Tobacco River Valley are warranted now that we know frogs occupy the nearby Chain-of-Lakes.

At this point, prognosis for survival of the two populations is uncertain. The Confederated Salish and Kootenai Tribes Wildlife Management Program on the Flathead Indian Reservation, 130 km to the south of Foy Lakes, is currently involved in a Northern Leopard Frog reintroduction project. Hopefully the success of this project, a rebound from one or both of the remaining populations in our study area, or perhaps discovery of other unknown populations will contribute to the persistence of the Northern Leopard Frog in western Montana.

Acknowledgments.—We thank R. Kerr, L. Johnson, A. Soukkala, D. Casey, C. Burtch, D. Burtch, D. Bergeron, and members of the Youth Conservation Corps and Montana Conservation Corps for assisting with surveys and G. Pisk, F. Egan, G. Daley, B. Stokely and B. Hayes for granting access to wetland sites on their property. This study was supported by a seed grant from the Declining Amphibian Populations Task Force in 2002.

A Simple Method for Housing *Xenopus* During Oviposition and Obtaining Eggs for Use in FETAX

The Frog Embryo Teratogenesis Assay – *Xenopus* (FETAX) is a 96-hr whole embryo teratogenesis test useful for detecting developmental toxicants in the environment (Bantle et al. 1994). The versatility of FETAX allows it to be used in screening pure and complex mixtures, toxicity reduction assays, determining structure-activity relationships, examining metabolism of teratogens, and investigating mechanisms of teratogenesis at the molecular and cellular levels (Bantle 1995). Adult *Xenopus* are generally easy to maintain in captivity and can be bred effectively using human chorionic gonadotropin (HCG). Standardized methods for general housing of adults have been developed (ASTM 1991). These standards recommend a 12 h day/12 h night photoperiod, water temperature should be 23°C, and densities of four to six frogs per 1800 cm^2 of water surface area. The sides of aquaria are to be at least 30 cm high and opaque with the water depth 7–14 cm.

During oviposition ASTM (1991) recommends use of 10–20 L glass aquaria fitted with 1-cm mesh suspended about 3 cm from the substrate. This allows the eggs to fall through the mesh where adults will be unlikely to ingest or damage them until removal by the investigator. Recommended mesh is currently nylon or plastic. Using glass aquaria can be dangerous as these can easily break and develop leaks during handling. It is also possible for the frogs to get under the mesh and drown, or damage and ingest eggs.

The standards provide for a second method in which the frogs are housed in two plastic dish pans at least 38 cm × 38 cm (1444 cm^2). These are stacked inside each other. The uppermost pan should be manually perforated with holes using a 1.5 cm cork-borer or other similar device. This is somewhat better than using aquaria. There is little risk of breakage and the frogs cannot become trapped in the egg chamber. Drilling the holes can be an arduous task and hole-placement must be done carefully to avoid extensive plastic bridges where eggs can attach themselves and later be destroyed.

The Rayburn laboratory has determined that sifting cat litter boxes (Fig. 1) provide a safe, effective alternative to either of the previous methods for housing *Xenopus* during oviposition. These containers have served well for breeding over 100 frogs in the last five years. Sifting cat litter boxes can be purchased at discount stores for around US $6.00. These containers are opaque and made of plastic, per ASTM (1991) recommendations and leak-proof. Each set comes with two pans, a sifting grate, and an open lid (Fig. 1).

The pans have a base area of 1260 cm^2 (30 × 42 cm), 184 cm^2 smaller than the ASTM (1991) standard. Each pan is 9 cm deep, allowing a water depth of around 7–8 cm, within the standard recommendations. One of these pans serves as the base housing the frogs. The sifting mechanism, intended for use to remove cat feces from the litter, is seated inside the base tray. The base of the sifting mechanism is composed of a plastic grate with consistent 1 × 2 cm holes. The grate provides adequate safe passageway for the majority of eggs to fall through. The space between the top of the grate and the bottom of the base-pan is sufficient (1–2 cm) to protect eggs from the adults. The lid provided with this kit (Fig. 1) sits on top of the base-pan. It projects 7 cm above the base pan. When the second pan is inverted and placed on top of the "lid," it provides an effective cover to prevent escapes and light penetration. Maintaining a dark environment is important to encourage these frogs to oviposit. The current model of sifting litter box has holes drilled on either side so that the whole assembly could be locked or otherwise fastened together to avoid escape or tampering. If similar models do not have these holes they would be easy to install with a small drill or cork-borer.

The eggs will stick to the bottom pan and can be easily removed using an inverted plastic petri dish to scrape them from the base. Eggs that stick to the grate can be removed in two ways. The first method is to use forceps or probes to remove eggs from the grate manually. This takes quite a bit of time. The second method in-

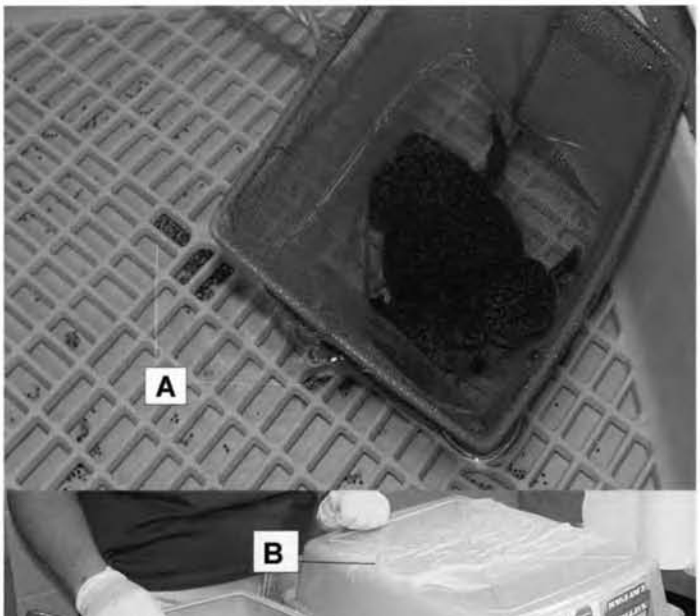

Fig. 1. Sifting cat litter boxes in use as oviposition chambers for obtaining eggs from *Xenopus* for use in FETAX: A) eggs beneath grate; B) cover pan; C) clamping lid; D) base pan.

volves using a dilute L-Cysteine solution. Drain water from the assembly until it is just covering the grate. Then add about 100 ml of 2% L-Cysteine (CAS #52-90-4, ASTM 1991). Gently stir or rotate the assembly (60 rpm on a rotary shaker). Embryos will fall from the grate into the bottom of the assembly in 20–60 minutes. Embryos will still have an inner jelly coat present. These embryos can be removed to a flask and dejellied using normal FETAX procedures except the time will be much shorter.

We recommend this technique to researchers for housing *Xenopus* during oviposition. The quantity and quality of eggs collected using this method is as good as with any of the standardized techniques, but without the problems outlined above. This method will recover 100% of eggs laid with little difficulty. There is little opportunity for adults to damage the eggs once they are laid, and this method provides a safe housing arrangement for adults during this period. This method might also be useful with other species of amphibians, especially those that lay dispersed eggs clutches.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 37, Number 1 (March 2006).

CAUDATA

PLETHODON HUBRICHTI (Peaks of Otter Salamander). **REPRODUCTION**. On 26 May 2005, while conducting a mark-recapture study in the contact zone for *Plethodon hubrichti* and *P. cinereus*, we discovered a *P. hubrichti* egg cluster under a rock imbedded in the soil. This is the first time a nest has been seen for this species (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Inst. Press, Washington, D.C. 587 pp.). Our study site (10 m × 10 m) is located near Onion Mountain, Bedford County, Virginia (USA). The egg cluster was attached to the top of a small cavity in the soil beneath the rock. Ten eggs were visible (2–3 additional eggs were likely in the center of the cluster but could not be seen without disturbing it) and the diameter of each of three eggs was 5.5 mm. Because the site was examined previously on 20 May 2005, it is likely the eggs were laid between 20–26 May. A brooding female was found attending the eggs during the initial and three subsequent site visits. She consistently retreated deeper into the crevice upon removal of the cover rock. On 7 July 2005, embryos with clearly visible eyes were moving within the eggs. Hatchlings were discovered clustered around the remains of the egg mass during a site check on 30 July 2005. Additional neonates were seen (N = 12) elsewhere on our site on 19 August 2005. It is likely that other nests were located either under large rocks that we could not move or below ground, since a total of 79 adult *P. hubrichti* had been marked on our site that year. The egg number and size, as well as the behavior of the brooding female, are similar to those noted for *P. cinereus* (Petranka, *op. cit.*). All neonates observed in this and another long-term study on timbering impacts (Reichenbach and Sattler, pers. obs., N = 126) were noted to be dark brownish-gray in coloring, bearing no distinct marks or color spots. This is in contrast to the description in Petranka (*op. cit.*), which states "hatchlings have a distinct dorsal stripe consisting of reddish spots." We have also noted that the characteristic brassy flecking on the dorsum of this species appears when the animals are ca. 25 mm SVL.

Submitted by **ANDREW KNIOWSKI** and **NORMAN REICHENBACH**, Department of Biology, Liberty University, Lynchburg, Virginia 24502, USA (e-mail: nreichen@liberty.edu).

ANURA

ATELOPUS VARIUS (Variable Harlequin Frog) and ***ATELOPUS ZETEKI*** (Panamanian Golden Frog). **ECTOPARASITES**. *Atelopus varius* and *Atelopus zeteki* are critically endangered (IUCN, Conservation International, and NatureServe. 2004. Global Amphibian Assessment. www.globalamphibians.org 4 April 2005) species known from premontane and lower montane wet forests and rainforests of the Atlantic and Pacific versants of the cordilleras of Costa Rica and Panama (Savage 2002. The Amphibians and Reptiles of Costa Rica. Univ. Chicago Press, Chicago, Illinois. 934 pp.; Dunn 1933. Occas. Pap. Boston Soc. Nat.

Hist. 8:65–79). Here we report the first observations of parasitism of *A. varius* and *A. zeteki* by ticks of the genus *Amblyomma*.

During monitoring studies of *A. zeteki* and *A. varius* in the Provinces of Panamá and Coclé, , ticks of the genus *Amblyomma* were observed parasitizing two female *A. zeteki* and one male and one female *A. varius*. These frogs were also observed to have numerous circular, raised scars on the venter, and less often on the dorsum, presumably due to previous tick infestation. An additional five females and one male *A. zeteki* were observed with similar scars but were not harboring ticks at the time. Three of these ticks were identified by RGR as larval (2) and nymphal (1) life stages of the genus *Amblyomma*. However, as none of these ticks were adult, identification to species was not possible and these specimens shall hereafter be referred to as *Amblyomma* sp.

The observations of ticks on *A. zeteki* were made by CLR and NEK in December 2004 and January 2005 (early dry season) during peak breeding activity, when the sex ratio was strongly male biased (ca. 1.8:1, CLR unpubl. data). However, of the seven frogs of this population observed with ticks and/or tick scars, six were female, indicating that the incidence of ectoparasitism by *Amblyomma* sp. on *A. zeteki* is likely higher for females than for males. This pattern could be produced if females and males are associated with different microhabitats outside the breeding season, or have different home ranges, or if females are longer lived than males and thus are exposed to ticks over a longer period of time. However, we have insufficient data to properly test these hypotheses. In contrast, in observations of two individual *A. varius* made by EJG in December 2002, one was male (four ticks on venter) and the other was female (35 ticks over all surfaces of the body). We have no information on sex ratio or the prevalence of scars at this site although scarred individuals were seen. It should be noted that many Neotropical amblyommines, especially the ubiquitous *Amblyomma cajennense*, are extremely abundant as immatures during the dry season, when a great range of hosts may be frequently and heavily attacked (Fairchild et al. 1966. *In* Wenzel and Tipton [eds.], Ectoparasites of Panama, pp. 167–219. Field Mus. Nat. Hist., Chicago, Illinois). Also, preimaginal tick populations are typically overdispersed (clumped), so that the odds of encountering them are not the same for all members of a host population (Robbins et al. 1998. J. Parasitol. 84:1303–1305).

The presence of numerous (up to 50) scars, presumably from previous infestation, on individual frogs suggests that ectoparasitism by *Amblyomma* sp. does not always cause mortality in *A. varius* and *A. zeteki*. However, six of the nine tick-infested and/or scarred frogs, when compared to a regression of weight against length (SVL), hereafter body condition, were found to be among the lowest 10% of the expected body condition distribution for their respective populations, indicating that tick infestation may carry a fitness cost for these frogs. The two other females and one male were among the middle 50% in body condition; however, these three individuals were also the smallest in body size (and therefore likely the youngest) and less extensively scarred than the other four females, which could account for their relatively good health.

Amphibian hosts of both ticks are chiefly true toads of the genus *Bufo*, especially the widely introduced Cane Toad, *B. marinus*, although *A. dissimile* has been collected from *B. fustiger* and *B. schneideri* (Cerny 1967. Wiad. Parazyt. 13: 533–537; Walton 1946. J. Parasitol. 32 [sect. 2, supp.]:18–19), while *A. rotundatum* has been reported from *B. arenarum* and *B. granulosus* (Díaz-Ungría 1957. Rev. Sanid. Asist. Soc. 22:457–467). *Atelopus* spp. are also members of the Bufonidae, but to our knowledge, this is the first report of parasitism by ticks of the genus *Amblyomma* on another bufonid genus.

We thank the Autoridad Nacional del Ambiente (ANAM) of Panama for permission to study *A. varius* and *A. zeteki* as well as the Smithsonian Tropical Research Institute (STRI) in Panama for logistical support. This work was completed with applicable federal and international permits and in compliance with guidelines of the Institutional Animal Care and Use Committee (IACUC #8831, University of Michigan).

BUFO A. AMERICANUS (Eastern American Toad). **LEUCISM.** Leucism is an autosomal recessive gene mutation in which animals lack functional melanophores and xanthrophores and possess minimal iridophores. The skin appears solid white with no pattern, but pigmentation is retained in the eyes (Bechtel 1995. Reptile and Amphibian Variants: Colors, Patterns, and Scales. Krieger Publ. Co., Malabar, Florida. 206 pp.). Complete albinos, partial albinos, and leucistic specimens have been observed for many species of North American amphibians and reptiles (Brame 1962. Abhandl. Und Ber. für Naturk. Und Vorgesch. 11:65–81; Drykacz 1981. SSAR Herpetol. Circ. 11. 31 pp.; Harris 1970. Bull. Maryland Herpetol. Soc. 6:21–27; Hensley 1959. Publ. Mus. Michigan St. Univ. 1, 159 pp.).

A leucistic adult female *Bufo a. americanus* (SVL 61 mm) was discovered in a partially wooded area near Sylva, Jackson County, North Carolina (35°22.5'N, 83°13.5'W) on 12 Oct 2004. It was subsequently transported to the Highlands Biological Station in Highlands, Macon County, North Carolina where it continues to survive in captivity. Although the eyes are dark, the skin of this individual is translucent white, and internal organs are clearly visible when it is backlit. Several photographs of this specimen were taken and are on file at HBS.

Although *B. americanus* is well-studied and widely distributed, I have found reports of abnormal pigmentation in this species only from central Kentucky (L. Hafley, pers. comm.) and northern Virginia (Bulmer 1975. Virginia Herpetol. Soc. Bull. 78:7). Similar appearing specimens of *B. fowleri* have been collected from Wake County, North Carolina in 1965 (NCSM 3884; Palmer and Braswell 1980. Brimleyana 3:49–52), and from Randolph County, North Carolina in 2005 (A. Braswell, pers. comm.), but to my knowledge this is the first record of leucism in *B. americanus* from west-

ern North Carolina.

I thank Alvin Braswell of the North Carolina Museum of Natural Sciences for his assistance.

BUFO BERGI (NCN). **REPRODUCTION**. *Bufo bergi* is associated with the flood plains of the Paraná and Paraguay rivers in northern Corrientes, eastern Chaco, Formosa, and northern and eastern Santa Fe, Argentina, and in adjacent southern Paraguay (Frost 2004. http://research.amnh.org/herpetology/amphibia/index.html). Few data are available to describe the reproductive traits of *B. bergi*. Fifteen individuals were captured in rice field habitat in Estancia La Norah (27°47'S, 58°46'W), 30 km S of Corrientes City, Corrientes Province, Argentina. Males (N = 10) were collected between 1 Nov 2001 and 5 Nov 2003; females (N = 5) were collected between 14 Oct 1999 and 19 Nov 2003. Specimens were captured in roadside ditches between 1800 and 2000 h, preserved in 10% formalin, and deposited at CECOAL (Centro de Ecología Aplicada del Litoral). Males measured: 33.3–40.5 mm SVL (mean 36.6; SD 2.4; CV 6.6%), body mass (BM) was 3.7–8.5 g (mean 6.2; SD 1.5; CV 24.9%); testes mass was less than 0.01 g. Testes were white in color and somewhat cylindrical in form. Females measured: 33.1–43.1 mm SVL (mean 40.4; SD 4.7; CV 11.6%), net body mass (BM) (body mass – ovary mass) was 5.1–9.8 g (mean 6.9; SD 2.0; CV 29.2%); ovary mass (OM) was 0.46–1.5 g (mean 0.7; SD 0.46; CV 62.5%); ovarian complement (OC) (number of mature ova) was 1043–2490 (mean 1751.8; SD 435.5; CV 24.9%); mature ova diameter (OD) was 0.30–0.7 mm (mean 0.5; SD 0.06; CV $\text{mean}_{[5\ \text{females}]}$ 11.17%; SD_{CV} = 2.2%; N = 500); reproductive effort (RE) (ovary mass/body mass %) was 4.7–19% (mean 10.7%; SD 5.4%; CV 50.1%); ovarian size factor (OSF) ($[_{mean}OC * {}_{mean}OD] / {}_{mean}SVL_{\text{gravid females}}$) (Duellman and Crump 1974. Occas. Pap. Mus. Nat. Hist. Univ. Kansas. 23:1–40) was 18. Ova were dark pigmented.

The differences in SVL and BM (net body mass for females) between males and gravid females were not significant (SVL [Mann-Whitney *U*-Test = 38.00; p = 0.11]; BM [Mann-Whitney *U*-Test = 29.00; p = 0.62]). *Bufo bergi* is an explosive breeder with breeding activity lasting one to a few days, with synchronous arrival of males and females. Table 1 summarizes the morphometric and reproductive features of males and females used in this study.

We thank Marta I. Duré for help with laboratory and fieldwork and CONICET for funding this study.

Submitted by **EDUARDO F. SCHAEFER** (e-mail: eclschaefer247@yahoo.com.ar) and **ARTURO I. KEHR** (e-mail: arturokehr@yahoo.com.ar), CECOAL-CONICET, C.C. 140, (3400) Corrientes, Argentina.

Table 1. Length, weight, and reproductive data for 10 male and 5 female *Bufo bergi* from 30 km S of Corrientes City, Corrientes Province, Argentina. SVL = mean snout–vent length ± 1 SD; BM = mean body mass ± 1 SD (net body mass for females); OM = ovary mass ± 1 SD; OC = mean ovarian complement (number of mature ova) ± 1 SD; OD = mean ova diameter ± 1 SD; RE = mean reproductive effort ± 1 SD; OSF = ovarian size factor ([OC * OD] / SVL).

Sex	N	SVL (mm)	BM (g)	OM (g)	OC	OD (mm)	RE (%)	OSE
Female	5	40.42 ± 4.69	6.89 ± 2.01	0.73 ± 0.46	1751.80 ± 435.50	0.50 ± 0.06	10.76 ± 4.39	18.00
Male	10	36.57 ± 2.41	6.16 ± 1.53	—	—	—	—	—

BUFO BERGI (NCN). **DIET**. *Bufo bergi* occurs in the floodplains of the Paraná and Paraguay rivers in northern Corrientes, eastern Chaco, Formosa, and northern and eastern Santa Fe, Argentina, and in adjacent southern Paraguay (Frost 2004. http://research.amnh.org/herpetology/amphibia/index.html). Little is known of the diet of this species. In Corrientes, it utilizes terrestrial and temporary pool habitat during the reproductive season. We analyzed stomach contents of 10 specimens (females: 41.26 ± 2.9 mm SVL, N = 3; males: 36.8 ± 2.29 mm SVL, N = 7) collected 15 km NW of Corrientes (27°28'S, 58°50'W), Corrientes, Argentina, between January 2001 and October 2002. The diet showed a marked predominance of ants in number (81.3%) and volume (48.9%). Table 1 summarizes data obtained by analysis of the stomach content. The values of diversity (Shannon Index, using natural logarithm) and niche amplitude (Levins index) were 0.63 and 1.46.

Table 1. Prey consumed by *Bufo bergi* (N = 10) from Corrientes, Argentina.

	N	%Total	Vol. (mm^3)	% Vol.	Freq.
INSECTA					
Coleoptera	37	13.8	373.1	42.9	8
Hemiptera	3	1.1	11.8	1.4	3
Hymenoptera (ants)	218	81.3	425.5	48.9	8
Homoptera	1	0.4	6.4	0.7	1
Larvae	8	2.9	52.2	6	4
ARACHNIDA					
Araneida	1	0.3	0.09	0.01	1
TOTAL	**268**	**100**	**869**	**100**	

Due to the low number of specimens available, we used a non-parametric test (Spearman Rank Correlation) for analysis of morphology and diet. We observed a positive and significant correlation between SVL and mouth width (rs = 0.76; p = 0.010); mouth width was also correlated with prey volume (rs = 0.63, p = 0.05). The number of ingested prey was not correlated with predator SVL (rs = 0.18, p = 0.61).

Data from specimens examined during this study suggest *Bufo bergi* is a generalized predator, actively foraging preferentially for ants.

Submitted by **MARTA I. DURÉ** and **ARTURO I. KEHR,** Centro de Ecología Aplicada del Litoral (CECOAL-CONICET), C.C. 291, (3400) Corrientes, Argentina (e-mail: martadure@yahoo.com).

BUFO HOUSTONENSIS (Houston Toad). **JUVENILE DISPERSAL.** *Bufo houstonensis* is an endangered anuran endemic to central-east Texas. While its breeding behavior has been well documented (Hillis et al. 1984. J. Herpetol. 18:56–72; Price 2003. Texas Parks and Wildlife Dept. Rep. 03-0401), the little published information concerning the juvenile life stages focuses mainly on predation (Freed and Neitman 1988. Texas J. Sci. 40:454–456), coloration (Mays and Freed 1985. Herpetol. Rev. 16:108–109), and growth (Greuter and Forstner 2003. Herpetol. Rev. 34:355–356; Quinn and Mengden 1984 Southwest. Nat. 29:189–195).

A Houston Toad egg string was surrounded with an aluminum flashing enclosure during Spring 2004 at the Griffith League Ranch (GLR) in Bastrop County, Texas, USA to monitor post-metamorphic behavior. Upon emergence, 993 individuals were captured and a single toe was clipped to identify the cohort year. The flashing was removed and 100 individuals were dusted with inert fluorescent powder (Radiant Color, T1 pigment) and released as a single group at the point of emergence. Fluorescent pigment was successfully used to track adult *Pelobates fuscus* (Eggert 2002. Herpetol. J. 12:69–74) and the same technique was applied in tracking juvenile Houston Toad dispersal. Toadlets were monitored immediately following release to determine if the pigment caused any malaise, and normal activity was observed. Metamorphs were located with a UV light (Raytech, Raytector-V Portable UV Light) for two consecutive nights and observed during the early morning hours of the day following their pigment-marked release. Metamorph locations were marked with marking flags; the area was left as undisturbed as possible, and the dispersal pattern was not analyzed until after the metamorphs left the pond's edge. It was our intention to follow the juveniles for a longer period, but during the afternoon of the third day, GLR received over 25 mm of rain. We believe this resulted in the pigment powder washing off of the toads as well as washing away trackways from the preceding night's dispersal.

We released the pigment-marked individuals at the point of emergence at the pond's edge. The tracks from individual metamorphs were not distinguishable within 0.5 m of the release site due to the large amount of powder deposited in a small area. However, tracks could easily be distinguished beyond the initial confused area of powder marks. When dispersing from the pond's edge metamorphs did not move in a straight line, but in a seeming random pattern that may have been foraging or shade seeking behavior. The majority of the pigment-marked individuals retreated into the water after release, which is normal behavior for post-metamorphic *B. houstonensis* (Greuter 2003. Unpubl. MS. Thesis, Texas State Univ. San Marcos, Texas. 80 pp.). We were able to track 15 individuals over two days. Within 48 hours after emergence, 8 of the *B. houstonensis* metamorphs had dispersed at least 4 m from the pond's edge. Mean dispersal distance was 3.24 m (range 0.7 m–5.13 m; median distance 3.43 m; N = 15) from the release point. The majority of the individuals (N = 12) were found buried under grass or sedge tussocks. The dispersal pattern did not increase in diameter from 24–48 h after marking. After the rainfall event, no pigment-marked metamorphs were relocated, however, toe-clipped individuals were quickly located, so we assumed the pigment washed off during the rainfall.

During this study, metamorphs did not show any ill effects due to the powder. Using this method was an easy, efficient, and cost effective way to track post-metamorphic juveniles. Nighttime observations of the movements of pigment-marked juveniles were easily monitored using UV light. Metamorphs were also observable during the day as the powder is highly visible, allowing us to observe toadlets without disrupting the point of emergence. We could visually track the individuals during day using binoculars from a distance of 3 m without difficulty. This is particularly relevant given the concentration of individuals at the pond's edge during the emergence period and the consequent care required to prevent accidental mortalities when trying to observe the behavior of these juveniles. We did not observe direct foraging during day or night surveys. Individuals appeared to be moving between shaded cover (daylight) or moving from one resting area to the next (night time). The technique does have an inherent weakness in very wet or rainy areas.

This study was conducted under permits issued to MRJF (USFWS: TE039544-1, TPWD: SPR-0102-191, and TXSTATE-IACUC: HGVMAD-02 and 5Qrs45-02).

COPHIXALIS SAXATILIS (Black Mountain Microhylid). **PREDATION.** The family Microhylidae is a large group of anurans occurring throughout the tropical and warm temperate regions of the World. In Australia they are confined to the wet forests of north-eastern Queensland and the drier monsoonal forests of Arnhem Land (Cogger 2000. Reptiles and Amphibians of Australia. Reed Publishing, Sydney, Australia. 808 pp.). Here I report predation of the rare microhylid *Cophixalis saxatilis* by the Northern Tree Snake (*Denrelaphis calligaster*). *Cophixalis saxatilis* is a large microhylid (40 mm SUL) restricted to the 6 km^2 gigantic black boulder jumble habitat of Black Mountain. While conducting fieldwork in the early evening (1800–1930 h EST) on Black Mountain (21–26 Nov 2000) I observed numerous *C. saxatilis* active and jumping among the exposed boulders at various locations. While walking along the edge of the mountain I observed a large Northern Tree Snake (*D. calligaster*; ca. 0.9 m TL) following an adult male *C. saxatilis* (ca. SUL 35 mm). After following the frog for ca. 4.5 m the frog stopped near the entrance of a rock crevice, apparently unaware of the snake's presence. As the snake approached the stationary frog it adopted a posture characteristic of this species before striking the frog. Upon being seized the frog emitted an audible squawk and struggled and kicked vigorously for over 10 minutes. During this time the snake chewed continuously and adjusted the position of the frog within its mouth, while the frog appeared to struggle less. After about 20 minutes the frog's body had been consumed and was visible as a bulge in the snake's body. Afterwards the snake

moved into a refuge under a large boulder along the edge of the mountain where it was no longer visible. The habitat occupied by *C. saxatilis* consists predominantly of a mosaic of boulder jumbles that may prevent the access of many of the typical terrestrial frog predators (i.e., snakes). Thus, apart from avian predators much of this habitat may represent a safe harbor and where the possibility of predation is restricted to the habitat edges.

CROSSODACTYLUS CARAMASCHII (NCN). **MORTALITY.** *Crossodactylus caramaschii* is a diurnal, stream dwelling anuran found at the Serra de Paranapiacaba, state of São Paulo, southeastern Brazil (Bastos and Pombal 1995. Copeia 1995:436–439). The species calls from emergent rocks in forest streams, where their eggs are laid and the tadpoles develop. During Sept 2003 in the municipality of Apiaí (24°33'45"S, 48°48'45"W; 925 m elev.) in the Atlantic Forest of the state of São Paulo, Brazil, five dead or moribund *C. caramaschii* were collected. These frogs were found recently dead on the rocks of the stream (N = 2) or were heard calling and died shortly after collection (N = 3). This situation is similar to the pattern reported from localities where local extinctions have been associated with infection by the chytrid fungus *Batrachochytrium dendrobatidis*, which causes chytridiomycosis (Berger et al. 1998. Proc. Nat. Acad. Sci. USA 95:9031–9036). Clinical signs of amphibian chytridiomycosis include abnormal posture, lethargy, and loss of righting reflex (Daszak et al. 1998. Emerg. Infect. Dis. 5[6]:735–748). The first record of *B. dendrobatidis* in Brazil was reported from Serra da Mantiqueira in *Hylodes magalhaesi* (Leptodactylidae), a diurnal, stream dwelling frog closely related to *Crossodactylus* (Carnaval et al. 2005. Froglog 70:3). Although the dead or moribund *C. caramaschii* collected were not tested for the presence of *B. dendrobatidis*, the pattern of death observed suggests infection by this fungus. Therefore, *B. dendrobatidis* might be more widespread in Brazil than reported.

Identification of these frogs was verified by Vanessa K. Verdade, and four were catalogued at the Museu de Zoologia da Universidade de São Paulo (MZUSP 133906–133909).

Submitted by **RICARDO A. GUERRA-FUENTES**, Museu de Zoologia da Universidade de São Paulo, Av. Nazaré, 481, CEP 04263-000, Brazil (e-mail: ricardoa@ib.usp.br); and **MARIANNA DIXO**, Universidade de São Paulo, Instituto de Biociências, Departamento de Ecologia, CEP 05508-900, Brazil.

DENDROPHRYNISCUS MINUTUS (Amazonian Tiny Tree Toad). **PREDATION**. On 3 Feb 2005 between 1300 and 1330 h, I observed predation involving a toad, a spider, and a group of ants in the forest litter next to a stream in the Reserva Florestal Adolpho Ducke (02°55'N, 59°59'W), Central Amazon, Amazonas, Brazil. While taking photos of an adult *Dendrophryniscus minutus* (SVL 15.8 mm) on the forest litter, it jumped about 30 cm and when in landed it was immediately attacked by a spider (*Ancylometes rufus*; 9.0 mm cephalothorax and abdomen length). The spider bit it on the dorsal region, and quickly moved away. The toad stayed motionless during the attack; it tried to move afterward but fell with its ventral region up, stretching and slowly contracting its hind and front legs. The spider came back shortly and grasped one of the toad's hind legs. After about two minutes an adult ant (*Megalomyrmex* cf. *balzani*; 8.2 mm) attacked the spider and tried to pull the toad away by one of the front legs. In less than two minutes five more adult ants of the same species attacked the spider which then abandoned the toad. The ants touched the toad for a few seconds but rejected it and followed in the spider's direction. The ants found, attacked, and immobilized the spider quickly. The toad, free of predators, but under the toxin's effect, tried to jump but was disoriented and still partially paralyzed.

The small diurnal bufonid *D. minutus* is an inhabitant of primary forest associated with leaf litter (Rodriguez and Duellman 1994. Publ. Nat. Hist. Mus., Univ. Kansas, 80 pp.). *Ancylometes rufus* is a terrestrial pisaurid spider that lives in the tropical forests of South America. They are most abundant next to streams and natural ponds and often feed on frogs (Menin et al. 2005. Phyllomedusa 4:39–47), tadpoles, and small fishes (Höfer and Brescovit 2000. Insect Syst. Evol. 31:323–360). Predation of toads by ants has been reported (Thomas and Allen 1997. Herpetol. Rev. 28:40–41; Zuffi 2001. Herpetol. Rev. 32:100–101; Fritz et al. 1981. Biotropica 13:158–159). Predation of adult *D. minutus* by adult *A. rufus* has been reported (Menin et al., *op. cit.*). Predation on amphibians by *A. rufus* can be common due to the abundance of this species in Amazonian forests and the large diversity of frogs in the different microhabitats occupied by this spider.

I thank Marcelo Menin and Karl Mokross for reviewing this note, Clarissa S. Azevedo and Thiago J. Izzo for identification of spider and ant, and José Tavares for assistance with fieldwork.

Submitted by **VICTOR F. V. PAZIN**, Laboratório de Ecologia de Comunidades, Instituto Nacional de Pesquisas da Amazônia, CP 478, CEP 69011-970, Manaus, Amazonas, Brazil; e-mail: victor@inpa.gov.br.

ELEUTHERODACTYLUS DIASTEMA (Common Tink Frog). **REPRODUCTION**. The genus *Eleutherodactylus* comprises a large number of poorly known tropical frogs that demonstrate direct development of terrestrial eggs and often exhibit parental care. Reproduction has been described for very few *Eleutherodactylus*, and for most species there are no data available on clutch size or parental care (Townsend 1996. *In* Powell and Henderson [eds.], Contributions to West Indian Herpetology, a Tribute to Albert Schwartz, pp. 229–239. SSAR Contrib. Herpetol. Vol. 12. Ithaca, New York). For those species for which information is available, data are often derived from one or two observations, and quite often these observations are contradictory (Townsend, *op. cit.*).

Eleutherodactylus diastema is a common frog of humid forests that ranges from Nicaragua to Panama and belongs to the subgenus *Eleutherodactylus* and the *martinicensis* series (Savage 2002. The Amphibians and Reptiles of Costa Rica. Univ. Chicago Press, Chicago, Illinois, 934 pp.). Dunn (1937. Copeia 1937:163–167) described one clutch of *E. diastema* from "Tablazo," Costa Rica and suggested male parental care. Ovaska and Rand (2001. J. Herpetol. 35:44–50) reported observations of five clutches from Barro Colorado Island, Panama, and suggested the species does

not demonstrate parental care. Here I provide an additional observation of reproduction in *E. diastema* from a lowland wet forest in Costa Rica.

At ca. 2130 h on 19 July 2005, I observed a female *E. diastema* in mature primary forest at La Selva Biological Station in the lowlands of northeast Costa Rica. I detected a nearby male calling from beneath a coiled fallen leaf in leaf-litter ca. 10 cm above the forest floor and within the buttress of a large tree. The female approached the calling male and disappeared behind the fallen leaf. I did not disturb the leaf-litter to continue observation.

I examined the site where the male was located at ca. 1030 h on 20 July 2005. There was a clutch of 11 spherical eggs (each ca. 6 mm in diameter) deposited in a small oblong (ca. 20 × 10 mm) mass attached to a dead leaf and concealed behind additional dead leaves. The clutch was located ca. 10 cm above ground level at the location where the calling male was observed the previous evening. Individual eggs were ca. 6 mm in diameter and uniformly off-white in color. The uniformly off-white coloration of the eggs and absence of visible embryos suggest that the clutch was newly laid. I observed no parent in a casual search of an area within a 50 cm radius of the clutch. The clutch was examined again at ca. 2100 h on 20 July, ca. 0940 h on 21 July, and ca. 0944 h on 22 July. On each observation, I counted the eggs and casually searched the immediate area in a radius of ca. 50 cm for the presence of any adult *E. diastema*. For each of these observations, all 11 eggs remained intact; none were predated or showed any indication of fungal infection or desiccation. I detected no adult *E. diastema* within the search area on any encounter.

This observation generally agrees with other observations of clutch size and courtship behavior for this species. This observation agrees with Ovaska and Rand's (*op. cit.*) observation of lack of parental care for populations in Panama, but not that of Dunn (*op. cit.*). Because *E. diastema* likely represents a complex of species (Savage, *op. cit.*), it is possible either that the mode of parental care varies within this species, or that variation in the mode of parental care varies among the species in a cryptic complex.

Submitted by **STEVEN M. WHITFIELD,** Florida International University, Department Biological Sciences, UP Campus, OE 167, Miami, Florida 33199, USA; e-mail: steven.whitfield@fiu.edu.

HYLA ALBOPUNCTATA (Spotted Tree Frog), ***H. MULTIFASCIATA*** (Many-banded Tree Trog), ***BARYCHOLOS TERNETZI*** (Savage's Goiás Frog), ***EPIPEDOBATES FLAVOPICTUS*** (Cerrado Poison Frog). **PREDATION.** The venomous wandering spider, *Phoneutria nigriventer*, and the fishing spider, *Anclyometes* sp., are common to the Cerrado biome of Central Brazil. Wandering spiders are widely foraging nocturnal predators while fishing spiders nocturnally and diurnally frequent waterside habitats, where they hunt for prey. These behaviors bring both spiders into contact with nocturnal amphibians. The venom of *P. nigriventer* may be potent in small vertebrates; a two-year old boy was bitten on the toe at one of our field sites and died three days later. Through herpetological inventories of this region of Cerrado since 1995, we have observed *P. nigriventer* feeding on a number of anurans, and *Anclyometes* sp. feeding on one frog. Our considerations of spiders as potentially significant predators of frogs in the Cerrado of Brazil began on 15 May 1990 (2000 h) when we observed *Anclyometes* sp. feeding on the dendrobatid frog, *Epipedobates flavopictus*. The observation was made near the town of Minaçu, along the Castelão River, State of Goiás, Brazil. The spider attacked the frog while it moved along the edge of a pool of water, biting it and holding on. Within minutes the frog was dead. Five minutes later, the spider dragged the frog into a crack between large boulders whereafter observations could not continue. On 10 July (beginning at 2200 h) and 12 July (beginning at 2330 h) 1998, we observed two *P. nigriventer* each feeding on recently captured *Epipedobates flavopictus*. Both frogs were still alive when observations began and no significant portion of either had been consumed. The locality lies along an unnamed road connecting the town of Minaçu and the Serra da Mesa hydroelectric power plant, Tocantins River, State of Goiás, Brazil. Observations were made along a drainage associated with "Club Elita," a social club off the unnamed road. In the same ravine on 18 July 1998 (2015 h) a species of mygalomorph spider (*Nhandu cerradensis*; Theraphosidae), was also observed feeding on *E. flavopictus*. The toxic alkaloids of this anuran apparently do not affect spiders or are tolerable enough to render the frog an appropriate prey species. All three observations of predation events at Club Elita occurred along a small drainage in a steep granitic ravine. All frogs were entirely consumed in less than three hours. On 13 July 1998 (beginning at 2230 h), at the same locality as with the *E. flavopictus*, we observed *P. nigriventer* feeding on a leptodactylid frog, *Barycholos ternetzi*. The frog was dead at the initiation of the observation and a significant portion of its abdomen had been consumed. After two hours of feeding, the spider abandoned the two legs of the frog, all that remained. On 16 July 1998 (beginning at 2130 h), we observed *P. nigriventer* feeding on a hylid frog, *Hyla multifasciata*, in the same locality as with the *Epipedobates* and the *Barycholos*. The frog had been recently captured and was alive at the initiation of the observations. Three hours later, the half of the frog that remained (head and arms) was abandoned by the spider. On 15 January 2004 (beginning at 1000 h) we observed *P. nigriventer* feeding on another hylid frog, *Hyla albopunctata*, at Ponte de Pedra hydroelectric power plant, right bank of the Corrente River, State of Mato Grosso, Brazil (Fig. 1).

FIG. 1. The venomous wandering spider, *Phoneutria nigriventer*, feeding on *Hyla albopunctata* in Central Brazil. Photo by I.J.T.

The habitat lies exactly on the ecotone between the Cerrado and Pantanal. We were drawn to the predation event through audible "scream-like" vocalizations emitted by the frog. This event differs from the others in that it occurred during the day, unusual behavior for the spider. At the initiation of observations, the frog was still alive and completely whole. In eight hours of feeding, only the legs of the frog remained and the spider abandoned them.

We thank Rick West for assistance in spider identification.

MELANOPHRYNISCUS CUPREUSCAPULARIS (NCN). **DIET**. *Melanophryniscus cupreuscapularis* is found in areas surrounding the type locality, in northeastern Corrientes, Argentina (Frost 2004. http://research.amnh.org/herpetology/amphibia/index.html). The species is primarily terrestrial although during the reproductive season it is found in temporary pools in groups of up to 10 individuals. Males vocalize while hidden in vegetation or floating on the surface of the water. Diet of this species has not been reported.

Twenty individuals were collected 15 km NW of Corrientes (27°28'S, 58°50'W), Corrientes, Argentina between July 1997 and April 1999. Twelve individuals contained identifiable prey items (female: 22.08 ± 1.81 mm SVL, N = 5; males: 21.82 ± 0.76 mm SVL, N = 7). Ants were the predominant prey in number (66.2%) and volume (85.8%), although beetles were found in the highest frequency. Table 1 summarizes data obtained by analysis of the stomach content. The values of diversity (Shannon Index, using natural logarithm) and niche amplitude (Levins index) for this species were 1.15 and 2.13.

We used a non-parametric test (Spearman Rank Correlation) for analysis of morphology and diet. We observed a positive and significant correlation between SVL and mouth width ($r^2 = 0.68$; $p = 0.015$); the number of prey ingested was significantly correlated with predator SVL ($r^2 = 0.76$, $p = 0.004$). Mouth width was not correlated with prey volume ($r^2 = 0.063$, $p = 0.84$).

Data from specimens examined during this study suggest *Melanophryniscus cupreuscapularis* is a generalized predator, actively foraging preferentially for ants.

TABLE 1. Prey consumed by *Melanophryniscus cupreuscapularis* (N = 12) from Corrientes, Argentina.

PHRYNOHYAS VENULOSA (Veined Treefrog). **DIET**. *Phrynohyas venulosa* has a wide distribution in Central and South America, ranging from the lowlands of Mexico to the Amazon Basin of Colombia, Ecuador, Peru, Venezuela, and Brazil; the Guianas, Brazil, Paraguay, Trinidad, and Tobago (Frost 2004. http://research.amnh.org/herpetology/amphibia/index.html). In Argentina, *P. venulosa* occurs in Jujuy, Salta, Formosa, Chaco, Corrientes, and Entre Ríos y Misiones (Cei 1980. Amphibians of Argentina. Monitore Zoologico Italiano MS). We examined the stomach contents of 20 specimens collected 15 km NW of Corrientes (27°28'S, 58°50'W), Corrientes, Argentina, between February 1994 and March 1999. Only 35% (N = 7) had identifiable stomach contents (males: 64.4 ± 16.3 mm SVL, N = 3; females: 76.6 ± 5.7 mm SVL, N = 4).

Ants were the predominant prey in number and beetles were better represented volumetrically. Table 1 summarizes data obtained by analysis of the stomach contents. The values of diversity (Shannon Index, using natural logarithm) and niche amplitude (Levins index) for this species were 1.15 and 2.08.

Due to the low number of specimens with identifiable prey we used a non-parametric test (Spearman Rank Correlation) for analysis of morphology and diet. A positive and significant correlation exists between SVL and mouth width ($r^2 = 0.85$; $p = 0.01$). The number of prey ingested was not correlated with predator SVL (rs

= 0.05, p = 0.90) and mouth width was not correlated with prey volume ($r^2 = 0.53$, $p = 0.21$).

Phrynohyas venulosa is an arboreal frog with low mobility. Based on diet and observed behavior of the specimens examined in this study it should be considered a generalized predator with a "sit-and-wait" strategy for obtaining prey.

Submitted by **MARTA I. DURÉ** and **ARTURO I. KEHR**. Centro de Ecología Aplicada del Litoral (CECOAL-CONICET), C.C. 291, (3400) Corrientes, Argentina (e-mail: martadure@yahoo.com).

RANA HECKSCHERI (River Frog). **PREDATION.** Few predators have been reported for *Rana heckscheri*. Allen (1938. Copeia 1938:50), Fogarty and Hetrick (1973. Auk 90:268–280), and Brown (1979. Brimleyana 1:113–124) reported Banded Water Snakes (*Nerodia fasciata*), Cattle Egrets (*Bubulcus ibis*), and a Rainbow Snake (*Farancia e. erytrogramma*) as predators of *R. heckscheri* tadpoles. Juvenile and adult *R. heckscheri* are reported to have toxic skin secretions (Ashton and Ashton 1988. Handbook of Reptiles and Amphibians of Florida—Part Three: The Amphibians. Windward Publishing, Inc., Miami, Florida. 191 pp.; Bartlett and Bartlett 1999. A Field Guide to Florida Reptiles and Amphibians. Gulf Publishing Co., Houston, Texas. 280 pp.), and Behler and King (1985. The Audubon Society Field Guide to North American Reptiles and Amphibians. Alfred A. Knopf, New York, 743 pp.) reported that "water snakes and indigo snakes become violently ill" after ingesting recent metamorphs.

On 3 Sept. 2005, we observed an adult female *N. fasciata* (ca. 850 mm TL) exhibiting what might best be described as a combination of active foraging and ambush behavior in the shallows of Old Levi Mill Lake (Poinsett State Park, ca. 10.6 km WNW of Pinewood, Sumter Co., South Carolina, USA). Recently transformed juvenile *R. heckscheri* were abundant along the lake's edges, and we saw several in the snake's immediate vicinity. We observed the snake for several minutes on multiple occasions during mid-day and early afternoon, but did not see it capture prey. At 1554 h, we captured and handled the snake, and it regurgitated a juvenile *R. heckscheri* (52 mm SVL, 14.0 g). We released the snake and deposited the frog in the North Carolina State Museum of Natural Sciences (NCSM 68547). To our knowledge, this represents the first report of natural predation on non-larval *R. heckscheri*.

TESTUDINES

ACTINEMYS MARMORATA (Pacific Pond Turtle). **SIZE**. To date the largest *Actinemys marmorata* reported was a male from Marin County, California, with a straight-line carapace length (SCL) of 223 mm and a plastron length (PL) of 193 mm (Fidenci 2005. Herpetol. Rev. 36:440). Here we report the measurements of three large *A. marmorata* captured from California Central Valley slough habitats adjacent to the Sacramento River, near Hamilton City (California, USA). Male #1: SCL = 241 mm; PL = 216 mm; carapace width at 8th marginal (CW) = 176 mm; shell height (SH) = 90 mm; mass = 1923 g. Male #2: SCL = 226 mm; PL = 210 mm; CW = 175 mm; SH = 74 mm; mass = 1402 g. Male #3: SCL = 223; PL = 209 mm; CW = 170 mm; SH = 83 mm; mass = 1564 g. All turtles were individually marked with filed notches in the marginal scutes and released at their capture sites. These captures represent the largest *A. marmorata* yet recorded within their range. All measurements were confirmed by John S. Campbell.

ACTINEMYS MARMORATA (Pacific Pond Turtle). **REFUGIA**. Pacific Pond Turtles are known to be shy and to escape quickly into deep pools when disturbed (Ernst et al. 1994. Turtles of the Unites States and Canada, Smithsonian Institution Press, Washington D.C. 578 pp.). They are reported to utilize undercut banks and submerged structures (i.e., rocks, logs, vegetation, etc.) as refugia (Holland 1996. Herpetol. Rev. 27:198–199; Reese and Welsh 1998. J. Wildl. Manage. 62:842–853). Holland (*op. cit.*) also reported an atypical instance of refugia use in an upland habitat. However, little else has been reported about upland or aquatic refugia by this species. Here I report the use of rodent burrows and aquatic silt loads as refugia by *A. marmorata*.

Beginning in Fall 2002, an effort was made to remove Bullfrogs (*Rana catesbeiana*) from a portion of Kellogg Creek in the Los Vaqueros watershed, in eastern Contra Costa County, ca. 57 km E of San Francisco, California (USA). Bullfrog removal was conducted to increase habitat suitability for the California Red-legged Frog (*R. draytonii*) and *A. marmorata*. Portions of the creek were isolated using sand bags and wire mesh fencing. These sections were then drained. Native fauna was removed during draining and placed in adjacent sections of creek—upstream of the area being drained.

Fifty-six *A. marmorata* were encountered during the draining phase of the project. Turtles were found free-swimming in shallow pools, attempting to move upstream or downstream, or were found buried in the bottom sediment of drained pools. On three separate days, turtles were also found within the burrows of Beaver (*Castor canadensis*) and Muskrat (*Ondatra zibethicus*) located in the bank of the creek.

We frequently observed turtles (ca. 30% of captures) utilizing bottom silt as refugia from our capture. As water levels were lowered, turtles moved to the bottom of pools where they appeared to "swim" into loose bottom silt. Although turtles were not visually detectable, they could be located by raking through the silt with both hands. Frequently turtles were found < 0.5 m into the silt. On one occasion 3 turtles were found deep (ca. 0.7–0.9 m) within an inactive earthen burrow made by a Beaver. A fourth was found ca. 0.3 m within a different Beaver burrow, and a fifth turtle was found ca. 0.3 m within a potentially active Muskrat burrow.

Holland (*op. cit.*) reported that *A. marmorata* typically use inaccessible microsites as refugia, including under logs, rocks, cut banks, within vegetation, and occasionally in substrate. During the work on Kellogg Creek, it appeared that turtles regularly sought refuge in bottom silt loads of natural pools and those created by Beavers. They also utilized large-rodent burrows, perhaps in response to the draining of pools where turtles were present.

Beavers provide suitable open-water habitat for *A. marmorata* when the two species are sympatric. However, Beavers might also provide refugia within their abandoned burrows, and also by piling loose silt at the base of their dams.

I thank Mary Shea and the Contra Costa Water District for support and assistance with this investigation.

CARETTA CARETTA (Loggerhead Seaturtle). **PREDATION.** Hatchling seaturtles have a large number of documented predators (Dodd 1988. U.S. Fish. Wildl. Serv., Biol. Rep. 88 [14], 110 pp.; Stancick 1995. *In* Bjorndal [ed.], Biology and Conservation of Sea Turtles, 2nd ed., pp. 139–152. Smithsonian Institution Press]. However, seaturtle predation by anuran amphibians is apparently unreported. Here, we document the predation of *Caretta caretta* hatchlings by the Cururu Toad (*Bufo jimi* Steveaux 2002), observed on two different occasions at the District of Arembepe, City of Camaçari, Bahia, Northeast Brazil (12°45'42.8"S, 38°10'05.5"W). Projeto TAMAR-IBAMA (the Brazilian National Sea Turtle Conservation Program) maintains a field station in this area. Some seaturtle nests are transferred to an open hatchery, which consists of a 130 m^2 area, surrounded by a fence, fully exposed to sun and rain, and located at the suprashore zone, at the vegetation line. Extensive wetlands are located very close to the sandy beach. Inside the fence, each nest receives an individual screen fence, where recently emerged hatchlings are temporarily retained and then released after data collection. Occasionally some of the hatchlings escape from the protective screens.On several occasions the presence of *Bufo jimi* inside the hatchery was noted, never more than one specimen at a time. In February 2003, attempted predation on *C. caretta* hatchlings by *B. jimi* was observed, when over 20 hatchlings of *C. caretta* and *Eretmochelys imbricata* escaped from the protective screens and dispersed through the hatchery. A toad, using a sit-and-wait strategy, was observed attempting to capture several turtle hatchlings. It initially appeared to have no success in swallowing them; all the captured hatchlings were released after the ingestion attempts and no successful predation was observed. However, the *B. jimi* specimen was then captured and sacrificed; necropsy and examination of stomach contents revealed a *C. caretta* hatchling with a straight-line carapace length of 46 mm. In January 2004, another *B. jimi* specimen was found inside the hatchery, beside one of the nests, where there was a retained *C. caretta* hatchling. This time there were no dispersed turtle hatchlings in the hatchery. This toad was also captured and sacrificed and necropsy revealed one *C. caretta* hatchling in the stomach (no measurements were possible due to carapace damage caused by digestion).

The *B. jimi* specimens were deposited at Museu Nacional do Rio de Janeiro (MNRJ 30804) and Museu de Biologia Mello Leitão (MBML 3670); the ingested *C. caretta* were deposited at Museu de Biologia Mello Leitão (MBML 1706-07).We are grateful to Ulisses Caramaschi for the identification of MNRJ 3804 specimen, and Célio F. B. Haddad, Luciano S. Soares, and Gustave G. Lopez for reviewing the manuscript. Projeto TAMAR-IBAMA is co-managed by Fundação Pró-TAMAR and is officially sponsored by PETROBRAS.

CHELONIA MYDAS AGASSIZII (East Pacific Green Seaturtle). **MALE NESTING.** The Green Seaturtle is the most common marine turtle species in the Galapagos Islands and the only species that nests in the archipelago. Nesting activity is concentrated between the months of December and May (Green 1994. *In* Schroeder and Wilheinghon [compilers], Proc. of the 13th Symp. on Sea Turtle Biology and Conservation. NOAA Tech. Mem. NMFS - SEFSC - 314:65– 68; Zárate and Dutton 2002. *In* Danulat and Edgar [eds.], Reserva Marina de Galápagos. Línea Base de la Biodiversidad, pp. 305–323. Fundación Charles Darwin/Servicio Parque Nacional Galápagos, Santa Cruz, Galápagos, Ecuador). The most important nesting beaches are Quinta Playa (Isabela Island), Bahía Barahona (Isabela Island), Las Bachas (Santa Cruz Island), and Las Salinas (Seymour Island). A monitoring program at these sites was established during nesting seasons during 2002–2005 and recorded 2756, 1913, 1569, and 724 nesting females, respectively ((Zárate et al. 2003. *In* Seminoff [compiler], Proceedings of the 22nd Annual Symposium on Sea Turtle Biology and Conservation, pp. 70–73. NOAA Tech. Memo. NMFS-SEFSC – 503 [Quinta Playa]; and Zárate, unpubl. data).

On 16 December 2004 and 21 February 2005 I observed apparent nesting behavior by male turtles, one at Bahía Barahona (Turtle 1, ID: GF497/GF440) and one at Las Salinas (Turtle 2, ID: LB772/LB773), respectively. These individuals were classified as males based on their tail length (TL: measured from the tip of the tail to the trailing edge of the carapace) and its prehensile character (Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Inst. Press, Washington, DC. 578 pp.). Both had tails longer than 20 cm, a male character (Wibbels 1999. *In* Eckert et al. [eds.], Research and Management Techniques for the Conservation of Sea Turtles, pp. 139–143. IUCN/SSC Marine Turtle Specialist Group Publ. No. 4). Turtle 1 was observed for about 1 h and 10 min; turtle 2 was observed for 45 min before it returned to the sea. Curved carapace lengths of Turtle 1 and Turtle 2 were 87.3 cm and 100.0 cm, respectively, whereas the TLs were 31.0 cm and 24.0 cm.

Both males were encountered while they were digging a body pit with their front flippers. Turtle 1 was observed excavating an egg chamber; its behavior was nearly identical to that of females observed during the same behavioral sequence. The completed egg chamber measured ca. 60 cm deep and 18 cm wide, and upon completion Turtle 1 remained in a laying position for 20 min prior to covering the egg chamber. Neither male was observed on a second occasion.

This is the first documented record of nesting behavior by male *C. mydas* in the Galapagos Islands, although similar observations have been made elsewhere (P. Pritchard, pers. comm. to S. Troeng). Cases are reported from Tortuguero National Park, Costa Rica (Troeng 2000. Chelon. Cons. Biol. 3:749–750) and Suriname (J. Schulz, pers. comm. to P. Pritchard). Explanations suggested for this phenomenon include possible endocrine disruption in males resulting in behavioral change (Troeng 2000, *op. cit.*) or intersexuality, as records in nature of individuals showing gonadal characteristics of both sexes occasionally occur (Limpus et al. 1994. Mem. Queensland Mus. 35:139–154). However, specific analyses on a case by case basis will be needed to identify precise causes for this behavior.

I thank the National Marine Fisheries Service – Southwest Fisheries Science (La Jolla, California) for providing financial support for this field study, and J. A. Seminoff for reviewing this manuscript.

Submitted by **PATRICIA ZÁRATE BUSTAMANTE**, Marine Conservation and Research Department, Charles Darwin Research Station, Santa Cruz Island, Galapagos Islands, Ecuador; e-mail: pzarate@fcdarwin.org.ec.

CHRYSEMYS PICTA BELLII **(Western Painted Turtle). DENSITY AND BIOMASS.** From 28 May to 29 June 2005 we trapped *Chrysemys picta bellii* in a 0.71 ha spring fed, human-made pond (maximum depth ca. 2 m), ca. 200 m from Blue Creek, 16.9 km NNE of the junction of Highways 27 and 26 in Oshkosh, Garden County, Nebraska, USA (see also Iverson et al. 2000. Herpetol. Rev. 31:238). The turtles were caught using four 15-m fyke nets (183 cm depth, 2.5 cm mesh, with 90 cm diameter hoop traps on each end) baited daily with fresh pieces of carp. We captured and marked a total of 106 *C. p. bellii* (34 females and 8 males > 150 mm carapace length; 29 females and 13 males 110–150 mm; and 22 others < 110 mm; range 84–190 mm carapace length and 70–840 g body mass), having a composite mass of 38.87 kg, a density of 149 turtles/ha, and a standing crop biomass of 54.7 kg/ha.

Although estimates of standing crop biomass are available for *C. picta* in New York (15.7–91.3 kg/ha; Zweifel 1989. Amer. Mus. Novitates 2952:1–55), Pennsylvania (4.3–106.4 kg/ha; Ernst 1971. J. Herpetol. 5:151–160; 1976. J. Herpetol. 10:25–33), Michigan (4.6–73.6 kg/ha; Iverson 1982. Oecologia 55:69–76; Congdon et al. 1986. Amer. Midl. Nat. 115:165–173), and Indiana (11.2 kg/ha; Wade and Gifford 1965. Proc. Indiana Acad. Sci. 74:371–374; Iverson 1982, *op. cit.*), these are the first measurements reported for the western subspecies *C. p. belli*, and for the western two-thirds of the species range. These data suggest that despite the much larger body size of *C. p. bellii*, and the low aquatic turtle species richness at this site and over most of its range, density and biomass are apparently similar to those of eastern populations.

Submitted by **JOHN B. IVERSON**, Department of Biology, Earlham College, Richmond, Indiana 47374, USA; **PATRICK J. BAKER, TIMOTHY J. MUIR,** and **BRIAN D. DISHONG**, Department of Zoology, Miami University, Oxford, Ohio 45056, USA.

EMYDOIDEA BLANDINGII **(Blanding's Turtle). DOUBLE-CLUTCHING.** Female Blanding's Turtles are generally believed to nest only once per season (M.J. Pappas et al. 2000. Chelonian Conservation and Biology 3[4]: 557-568; Standing, K.L. et al. 2000. Chelonian Conservation and Biology 3[4]: 637-642). Here, we report an observation of a female Blanding's Turtle in Minnesota that nested twice during the 2003 nesting season.

Adult female Blanding's Turtles were radio-tracked during the 2003 activity season at Elm Creek Park Reserve, Hennepin County, Minnesota, USA, during a multi-year study of habitat use and movement patterns of turtles in this population. During the evening of 7 June, female 2040 was observed beginning a nesting foray (the earliest such foray by this turtle in four monitored nesting seasons). At 2145 h on 9 June she was observed from a distance in a sparsely vegetated area occasionally used for nesting by other Blanding's Turtles. At this time she did not appear to be actively digging, and the researcher left the area to avoid disturbing her. The researcher returned at 2215 h and found a skunk eating an egg at the spot at which the turtle had been observed earlier. The skunk was chased away, and a nest containing intact eggs was found at this location. Female 2040 was sitting nearby in tall grass. By 11 June, this turtle had returned to her home wetland.

On 26 June, female 2040 was again observed traveling on land. On 29 June, she was found covering what appeared to be a completed nest at 2015 h. This nest was opened by the researcher to confirm completion, and eleven eggs were found. Female 2040 had returned to her original wetland by 4 July.

Although these field observations strongly suggested that female 2040 had laid both clutches of eggs, she had not actually been seen during any stage of the construction of the 9 June nest. To confirm that this nest had indeed been constructed by female 2040, a maternity test was conducted by comparing the genotypes of the hatchlings collected from both nests to that of female 2040 using microsatellite DNA. Tissue samples were collected from the hatchlings and the adult female by snipping off the distal 2 mm of the tail. DNA was extracted using a 5% solution of Chelex resin and PCR was amplified as described by Osentoski et al. (Molecular Ecology Notes 2: 147-149). Microsatellites at three loci were sized and visualized using GENESCAN analysis software v.3.1 (ABI Prism) at the Advanced Genetics Analysis Center, University of Minnesota.

One allele per locus in each hatchling genotype was identical to female 2040's genotype at each locus, which strongly supports the conclusion that female 2040 nested twice during 2003. Additionally, at all three loci tested, no more than three alleles were detected among all hatchlings from the two clutches, and the complement of alleles detected at any given locus was identical between the two clutches. Not only do these data support the conclusion that female 2040 laid both clutches, but both of these clutches also appear to have been sired by the same male.

Funding for this research came from the Minnesota Department

of Natural Resources - Natural Heritage and Nongame Wildlife Program and State Wildlife Grants, Three Rivers Park District, Sigma Xi Grants-in-Aid-of-Research, Minnesota Herpetological Society, and the James Ford Bell Museum of Natural History's Dayton-Wilkie Natural History Funds.

TERRAPENE, T. CAROLINA, T. C. BAURI, T. C. MAJOR (American Box Turtles, Eastern Box Turtle, Florida Box Turtle, Gulf Coast Box Turtle). **MAXIMUM SIZE.** Although box turtles of the genus Terrapene reached and even exceeded 300 mm maximum carapace length (CL) during the Plio-Pleistocene (Auffenberg 1958. Bull. Florida State Mus. 3:53–92; Milstead 1969. Bull. Florida State Mus. 14:1–113; assigned to *T. carolina putnami*), very few individuals exceed 200 mm today. The largest modern box turtles recorded were two male *T. c. major* from St. Vincent Island, Franklin County, Florida, with reported carapace lengths of 216 and 210 mm (Auffenberg, *op. cit.*; specimens said to have been skeletonized, apparently unavailable). This note provides measurements for a substantially larger living *Terrapene* (male *T. c. major*), the largest known Recent female (*T. c. major*), and the largest recorded Florida Box Turtle (*T. c. bauri*, male). Measurements of additional large turtles are also included (Table 1) because of their potential value to studies of allometric growth in the genus.

In the living collection of Brechtel (BB) is a massive male *Terrapene carolina* (R-553; UF 143641, 2 color transparencies) with a CL of 235 mm, plastron length (PL) of 217 mm, carapace width (CW) of 179 mm, and body mass of 2.1 kg; additional measurements are provided in Table 1. Although provenance of the turtle is uncertain, its morphology and coloration are clearly consistent with *T. c. major* and highly reminiscent of turtles from the region of the Apalachicola lowlands of western Florida. The carapace is strongly flared posteriorly and dark black-brown in color, with light yellow radiating spots on the costals; the plastron, head, and legs are also dark black-brown. The CL of 235 mm exceeds Auffenberg's largest reported specimen by 19 mm.

A second large male (R-561; UF 144571, three digital color photographs), collected in 2003 in the Apalachicola National Forest, Liberty County, Florida, was given to M. Aresco, who measured, photographed, and released it; its CL of 213 mm is only 3 mm shy of Auffenberg's (1958) previous record. The carapace was black with a yellow keel, the plastron yellow, and jaws white.

The largest recorded female *Terrapene* is an adult female *T. c. carolina* from New York (Table 1; Cook et al. 1972. Int. Turt. Tort. Soc. J. 6:8–17), with a CL of 198 mm, PL of ca. 186 mm (sum of anterior and posterior plastral lobe lengths of 76 and 110 mm, respectively), CW of 146 mm, and body mass of 1.395 kg. DRJ collected a very large female *T. c. major* (R-554; UF 143642, 3 color transparencies; currently maintained alive) crossing a Leon County, Florida, road in 2003. Both ends of the carapace had been truncated (by an estimated 3–5 mm anteriorly and 5–8 mm posteriorly) by old, well-healed injuries reminiscent of turtles injured by mowing (G. Guyot, pers. comm.) or possible chewing by a vertebrate predator. Nonetheless, her PL (204 mm), CW (154 mm), and body mass (1.59 kg) all substantially exceed corresponding measurements of the giant New York female. The shell height of 104 mm may also be a record for any modern representative (of either sex) of the species. Her coloration of yellow streaks and spots on a brown carapace, yellow plastron, and mostly brown head and feet are typical of many *T. c. major*.

Although Dodd (2001. North American Box Turtles: a Natural History. Univ. Oklahoma Press, Norman. 231 pp.) gave 166 mm as the record size CL for *T. c. bauri*, Pritchard (1980. Chelonologica 1:113–123) documented a much larger male (Chelonia Research Institute PCHP 1440, Lee County, Florida) that measured 187 mm CL and 138 mm CW; the CRI collection includes a second large male (PCHP 6147) of 183 mm CL. In BB's living collection are several large males, including one (R-557, now in DRJ living collection; UF 143643, 3 color transparencies) with a CL of 190 mm and CW of 144 mm. Additional measurements of this record male are given in Table 1, along with measurements of two other large living males (R-562, 563) that exceed the maximum size given by Dodd (*op. cit.*). Although their provenances are uncertain, the first and third stem from a rescued private collection in the Florida Keys, Monroe County, and the second is believed to have originated in Marion County, north-central Florida. The relatively flat shell and flared peripherals of the largest are consistent with *T. c. bauri* from the Florida Keys (Auffenberg, *op. cit.*). All three have black carapaces with narrow, radiating yellow lines as typify *T. c. bauri*. The throat of the largest male is colored by a deep blue iridescence.

Although some of our data are drawn from captive animals, we believe that most or all of their growth to record sizes was achieved prior to captivity. Even if otherwise, this note documents the genetic potential of *Terrapene carolina* to achieve larger sizes than

TABLE 1. Measurements, sex, and subspecific identities of six *Terrapene carolina* measured alive during 2003-2004; mass in g, all other measurements in mm. CL, carapace length; PL, plastron length; CW, carapace width; SH, shell height; APLL, anterior plastron lobe length; APLW, anterior plastron lobe width; PPLL, posterior plastron lobe length; PPLW, posterior plastron lobe width. Measurements of CL and PL are maximum.

TRACHEMYS SCRIPTA SCRIPTA (Yellow-bellied Slider). **FIRE ANTS AND NEST FAILURE.** On 29 June 2005 I witnessed a female *Trachemys scripta scripta* attempting to nest on the banks of a 10 acre pond in Lancaster, South Carolina, USA. This turtle was part of a previous study and she had been marked and her plastron length (19 cm) recorded. Initial observation revealed that she had already excavated a nest hole and deposited one egg, but fire ants (*Solenopsis geminata*) were attacking her. During the attack she swiped her face with her front claws and retracted her head; she also gasped and bit at the ants in an attempt to remove them. The attack lasted for about five minutes more when she abandoned the nest without covering the one egg. Upon entering the water she thrashed about in an apparent attempt to remove the ants. Ants were observed entering the nest and attacking the egg. On subsequent trips to the pond I did not see the egg or evidence of additional nesting attempts.

CROCODYLIA

CAIMAN CROCODILUS YACARE (Pantanal Caiman). **AESTIVATION**. Under conditions of water stress, some crocodilians aestivate for months in mud or holes (e.g., *Crocodylus niloticus*: Guggisberg 1972. Crocodiles: Their Natural History, Folklore and Conservation. Davies and Charles, Redwood Press Limited. 195 pp.; *Caiman crocodilus crocodilus*: Staton and Dixon 1975. Mem. Soc. Cienc. Nat. La Salle 35:237–266; *Crocodylus porosus*: Magnusson and Taylor 1979. Copeia 1979:478–480; *Crocodylus palustris*: Whitaker and Whitaker 1984. J. Bombay Nat. Hist. Soc. 81:297–317; *Crocodylus johnstoni*: Walsh 1989. Aust. Zool. 25:68–70). In response to disturbance, *Caiman crocodilus yacare* are known to leave pools to bury themselves under leaf litter in forested sites or in the mud around lakes (Campos et al. 2003. Copeia 2003:628–634), but published observations are lacking for caiman engaging in seasonal aestivation. Hence, here we report data on aestivating behavior by *C. crocodilus yacare* in the Brazilian Pantanal.

Observations on *C. crocodilus yacare* terrestrial activity were made at Campo Dora Ranch, an area with seasonal rivers; and Nhumirim Ranch, an area with many isolated lakes, in the Pantanal of Nhecolândia (Campos et al. 2003, *op. cit.*). This area experiences pronounced dry (August–December) and wet (January–May) seasons. Over 70 days beginning August 1993, we monitored 13 caiman (11 females, 2 males) using radiotelemetry; 7 in Campo Dora Ranch and 6 in Nhumirim Ranch. Radios were attached with nylon line to the last pair of double tail crests (*fide* Munoz and Thorbjarnarson 2000. J. Herpetol. 34:397–403). Each caiman was located 13 times at intervals averaging 5.5 days; and whether they were in the water or on land was noted.

Of the 13 caiman monitored during the dry season, we found 4 aestivating in either leaf litter or mud on different occasions (Table 1). For the four individuals that were aestivating (all females), the proportion of time that each was found buried varied from 0 to ca. 60% (Table 1). Whether aestivating Pantanal *C. crocodilus yacare* are responding to dry conditions, lack of food, or both is unclear (see Schmidt-Nielsen 1975. Animal Physiology. Cambridge University Press, 699 pp.). In the Pantanal, aestivating caiman without radio transmitters are almost impossible to detect because they typically do not respond to disturbance; we found only one non-radioed caiman buried in mud along a river margin, and this individual also did not respond to disturbance. Moreover, if any caiman aestivated over an interval shorter than our sampling resolution, this pattern would have gone unrecorded. Recognizing the frequency and seasonality of aestivation behavior is important because ignoring it can result in underestimating population size from direct counts, such as those used in the Venezuelan management program (Thorbjarnorson 1991. *In* Robinson and Redford [eds.], Neotropical Wildlife Use and Conservation, pp. 217–235. University of Chicago Press, Chicago, Illinois) and aerial survey program in the Pantanal (Coutinho and Campos 1996. J. Trop. Ecol. 12:741–747; Mourão et al. 2000. Biol. Conserv. 92:175–183). Our data provide only a preliminary glimpse of the aestivation pattern of some *C. crocodilus yacare* females over a relatively short seasonal interval; more resolved surveys over the entire seasonal range will be required to fully understand aestivation in *C. crocodilus yacare*.

This study is part of a doctoral dissertation by ZC submitted to the Federal University of Minas Gerais under the supervision of Gustavo Fonseca and WM, and was financed by Embrapa Pantanal, WWF-USA, Fundação O Boticário, and Conservation Interna-

TABLE 1. Size, sex, and aestivation habitat data for radio-telemetered *Caiman crocodilus yacare* in the Brazilian Pantanal. Percentage of time found in the aestivation habitats indicated is a function of the 13 times animals were located at intervals averaging 5.5 days.

LACERTILIA

ANOLIS CAROLINENSIS CAROLINENSIS (Northern Green Anole). **BEHAVIOR**. *Anolis carolinensis*, among the best-studied anoline lizards, is arboreal and generally uses any type of forested habitat and can be found in vegetation around urban and suburban areas (Mount 1975. Reptiles and Amphibians of Alabama. Auburn University Experiment Station, Auburn, Alabama. 347 pp.), hardwood hammocks and freshwater marshes, and coastal marshes (Bartlet 2006. Louisiana Coastal Marshes online at: http://www.uvm.edu/~jbarlet/nr260/animal%20life/animallifefinal.htm; Clark 1976. The Sanibel Report: Formulation of a Comprehensive Plan Based on Natural Systems, online at: http://www.worldpolicy.org/globalrights/environment/report/chapter4.html; Florida National Parks & Monuments Association 1996. Reptiles and Amphibians of Everglades National Park, online at: http://www.fiu.edu/~glades/education/reptilebr.htm). Although *A. carolinensis* has been described in these publications as using vegetation around water or in wetland situations, to our knowledge, use of floating mats of rooted vegetation is unreported. Hence, here we describe an observation of *A. carolinensis* using a floating mat of alligatorweed (*Alternanthera philoxeroides*) in central Alabama.

On 10 October 2005, ARG observed an adult (ca. 6.5 cm SVL, sex undetermined) *A. c. carolinensis* walking on an *A. philoxeroides* mat growing in shallow water along the shore of Beaver Lake in Oak Mountain State Park, Pelham (33°19'00"N, 86°35'50"W; datum: WGS84; elev. 55 m). The next day, both authors observed another adult (ca. 6.5 cm SVL, sex undetermined) in a different area of the lake performing the same behavior. The second animal readily ran across the surface of the mat, under the overhanging roots of a pine growing on the shoreline, and up the trunk of the tree. It was captured and positively identified by the senior author, and released at the point of capture.

Why these *A. a. carolinensis* performed this behavior is unclear. Alligatorweed presents a floating mat that can become interwoven, dense with leaves forming a nearly continuous mat, which can easily support the weight of *A. a. carolinensis* without sinking (in this case, many leaves on the stems were missing and the plants were somewhat brown which was likely due to the onset of cooler weather). The lizards may have been venturing onto the alligatorweed to capture invertebrates lurking on the plants and water surface.

ASPIDOSCELIS EXSANGUIS (Chihuahuan Spotted Whiptail) ×***ASPIDOSCELIS SEXLINEATA VIRIDIS*** (Prairie Racerunner). **REPRODUCTIVE POTENTIAL.** Triploid parthenogenetic *Aspidoscelis exsanguis* (nomenclature based on Reeder et al. 2002. Am. Mus. Novitat. 3365:1–61), derived from a 2-stage hybridization sequence involving 3 gonochoristic species (Good and Wright 1984. Experientia 40:1012–1014), is syntopic with *A. sexlineata viridis* on the east side of Sumner Lake, Sumner Lake State Park, De Baca County, New Mexico (34°36'N, 104°24'W, WGS84; elev. 1311 m). On 2 July 1998, JMW collected a male lizard (University of Arkansas Department of Zoology = UADZ 6241) at this site with the basic striped and spotted adult dorsal color pattern of all-female *A. exsanguis*; however, such a male can only be a tetraploid hybrid resulting from a haploid sperm of *A. sexlineata viridis* ($1n = 23$) fertilizing the unreduced egg of an *A. exsanguis* ($3n = 69$). *Aspidoscelis exsanguis* has been identified as a participant in two other hybridizations. Neaves (1971. Breviora 381:1–25) described the karyotype of a female *A. exsanguis* × *A. inornata*, and Taylor et al. (1989. J. Herpetol. 23:202–205) identified a male hybrid as having been fathered by either an *A. inornata* or *A. marmorata* (= *tigris*) male. Here, we detail the morphological and histological examination of the Sumner Lake *A. exsanguis* × *A. sexlineata viridis* hybrid.

Based on Walker et al. (1989. Copeia 1989:1059–1064) and Taylor et al. (2001. Am. Mus. Novitat. 3345:1–65), JMW described the gross reproductive morphology of the preserved hybrid. Based on Goldberg and Beaman (2003. Herpetol. Rev. 34:143), SRG histologically examined the left testis and left epididymis of the hybrid and assessed its previous reproductive functionality.

The preserved hybrid was 62 mm SVL (mass unavailable). Compared to male *A. sexlineata viridis* of similar age, its testes (mean dimensions of both = ca. 4 × 6 mm), epididymides, and hemipenes were of expected size and structure. Histology of the left testis indicated that the hybrid was undergoing early spermiogenesis. As reported for other teiid lizards (Lowe and Goldberg 1966. J. Morph. 119:277–281), a circumtesticular tunic 1–3 Leydig cells thick surrounded the left testis. Clusters of metamorphosing spermatids were present and tails of spermatozoa projected into the lumina of the seminiferous tubules. Sperm were also present in the sectioned epididymis.

This *A. exsanguis* × *A. sexlineata viridis* hybrid seemed capable of inseminating females of *A. exsanguis*, *A. sexlineata viridis*, and/or *A. tesselata* at the Sumner Lake site, but we do not necessarily infer that its presumed diploid sperm ($2n = 46$) could have contributed to production of either fertile or infertile polyploid hybrids. Nevertheless, the hybrid likely would have interfered with normal reproduction in females of these three species should any of them have been inseminated. Taylor et al. (2001, *op. cit.*) provided indirect histological evidence that the more numerous triploid hybrid males of *A. tesselata* × *A. marmorata* (N = 12) collected at Arroyo del Macho, Chaves County, New Mexico, may have inseminated congeneric females at this site.

Collection of UADZ 6241 was made under authority of permit 1850 issued to J. E. Cordes (Subpermittee JMW) in 1998 by the New Mexico Department of Game and Fish. Access to Sumner Lake State Park for this purpose also required a Special Use permit granted to JMW in 1998 from the Energy, Minerals and Natural Resources Department, New Mexico State Park and Recreation Division.

TAYLOR**, Department of Biology, Regis University, Denver Colorado 80221, USA (e-mail: htaylor@regis.edu).

ASPIDOSCELIS LINEATISSIMA (Twelve-lined Whiptail). **DIET**. The genus *Aspidoscelis* includes among the most important insectivorous lizards (Bostic 1966. Herpetologica 22:81–90; Paulissen 1987. Southwest. Nat. 32:395–397; Anderson 1993. *In* Wright and Vitt [eds.], Biology of Whiptail Lizards (Genus *Cnemidophorus*), pp. 83–116. Oklahoma Mus. Nat. Hist., Norman; Eifler and Eifler 1998. J. Herpetol. 32:24–33; Gadsden and Palacios-Orona 2000. Act. Zool. Mex. 79:61–76; Vitt and Pianka 2004. *In* Pérez-Mellado, Riera and Perera [eds.], The Biology of Lacertid Lizards, pp. 139–157. Evolutionary and Ecological Perspectives. Institut Menorquí d'Estudis, Recerca). Although *Aspidoscelis* diet is generally described as consisting of insects, the food habits of *A. lineatissima* are unknown.

On 6 May 2004 (dry season), MAGR captured an adult male of *A. lineatissima* (86 mm SVL, 12.5 g, 19°31'35.3"N, 105°04'06.6"W, datum: WGS84; 15 m elev) at Reserva de la Biosfera Chamela-Cuixmala (19°22'03"–25'11"N, 104°56'13"–03'25"W). Dominant vegetation is tropical dry forest with a wet season occurring July–October and a dry season November-June. Examination of its stomach contents revealed a partially digested snake, *Conophis vittatus* (90 mm SVL, 0.75 g). The head of the *C. vittatus* was totally digested but the rest of the body was intact.

Conophis vittatus, a terrestrial oviparous snake that occurs along the Pacific coast of México, is diurnal (Ramírez-Bautista 1994. Cuaderno 23. pp. 72–73. UNAM, México), and hence, would have opportunity to be found by *A. lineatissima*. This represents the first record of any *Aspidoscelis* feeding on *Conophis vittatus*.

Méndez-de la Cruz Fausto verified the identity of the snake. The *A. lineatissima* (IBH 14905) and *Conophis vittatus* (IBH 13905) were deposited in Colección Nacional de Herpetología, Instituto de Biología, Universidad Nacional Autónoma de México.

COLOPUS WAHLBERGII (Wahlberg's Kalahari Gecko). **ENDOPARASITES.** *Colopus wahlbergii* occurs in sandy plains with scattered vegetation and ranges from the Kalahari region of Botswana, extending into the Republic of South Africa, Namibia and southwest Zimbabwe (Branch 1998. Field Guide to Snakes and other Reptiles of Southern Africa, Ralph Curtis Books, Sanibel Island, Florida. 399 pp.). Adults measure between 45-61 mm SVL (Branch, *op. cit.*). To our knowledge, no reports of endoparasites exist for *C. wahlbergii*. The purpose of this note is to report a species of Cestoda, *Oochoristica truncata* and a species of Nematoda, *Spauligodon smithi* in *C. wahlbergii*.

Coelomic cavities and small and large intestines of 20 *C. wahlbergii* (mean SVL = 50.6 mm ± 4.4 SD, range: 40-58 mm) from Botswana, Kgalagadi District, 11 km S Tsabong, (26°08'S, 22°28'E, datum: WGS72; elev. 960 m) collected in 1970 were borrowed from the herpetology collection of the Natural History Museum of Los Angeles County (LACM 116407, 116410-116413, 116421, 116423-116424, 116428, 116430, 116436-116437, 116440, 116448, 116454, 116458, 116464, 116466, 116471, 116477), Los Angeles, California and examined for helminths. Stomachs were unavailable for examination. One female (LACM 116423) contained three cestodes in the small intestine. One male (LACM 116424) contained 6 nematodes (4 males, 2 females) in the large intestine. Cestodes were regressively stained in hematoxylin, mounted in Canada Balsam, studied as whole mounts and identified as *Oochoristica truncata*. Nematodes were cleared in a drop of concentrated glycerol on a glass slide, cover-slipped, and identified as *Spauligodon smithi*. They were deposited in the United States National Parasite Collection, Beltsville, Maryland: *Oochoristica truncata* USNPC (97451); *Spauligodon smithi* USNPC (97452).

Oochoristica truncata is widespread in Africa where it is known from agamid, chameleonid, corydalid, gekkonid, scincid lizards and boid and colubrid snakes (Goldberg and Bursey 2004. Afr. Zool. 39:111-114). *Oochoristica* utilize an intermediate host; infection is through the host's diet (Conn 1985. J. Parasit. 71:10-16). *Spauligodon smithi* is previously known from the gekkonid *Ptenopus garrulus* (Goldberg and Bursey 2002. Afr. Zool. 37:43-46) and lacertid *Nucras tessellata* (Goldberg and Bursey 2004. Afr. Zool. 39:111-114. *Spauligodon smithi* has a direct life cycle with no intermediate host; infection occurs through the ingestion of eggs (Anderson 2000. Nematode Parasites of Vertebrates: Their Development and Transmission, CABI Publishing, Wallingford, U.K. 650 pp.). *Colopus wahlbergii* is a new host record for *O. truncata* and *S. smithi*.

We thank Christine Thacker (LACM) for permission to examine specimens and Sean Kark and Nicholas Scott (Whittier College) for assistance with dissections.

Submitted by **STEPHEN R. GOLDBERG,** Department of Biology, Whittier College, Whittier, California 90608, USA: sgoldberg@whittier.edu and **CHARLES R. BURSEY,** Department of Biology, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania 16146, USA: cxb@psu.edu.

LEIOCEPHALUS PSAMMODROMUS (Turks and Caicos Curly-tail Lizard). **NECROPHAGY**. Despite their abundance and distribution throughout the Caribbean, relatively little is known about the natural history of lizards in the genus *Leiocephalus*. In particular, few reports exist on their diets. Here, we report on an observation of necrophagy in *L. psammodromus* from the Turks and Caicos Islands.

At 0950 h on 12 March 1974, JBI observed a male *L. psammodromus* (91 mm SVL) consuming a dead *Anolis scriptus* on the southwest portion of Pine Cay (21°54'N, 72°06'W, datum: WGS84; elev. 1.5 m). The observation was made in the rocky coppice vegetation zone of the island ("SW Blind" site; Iverson 1979: Bull. Florida State Mus., Biol. Sci. 24:175–358). The anole had been regurgitated by a *Cyclura carinata* at 1345 h the previous

day, and thus had been dead for at least 20 h.

Previous reports of the diets for some *Leiocephalus* have reported saurophagy (e.g., *L. barahonensis*: Micco et al. 1997: Herpetol. Nat. Hist. 5:147–156; *L. carinatus*: Schoener et al. 1982: Oecologia 53:160–169; *L. cubensis*: Schwartz and Henderson 1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. Univ. Florida Press, Gainesville; *L. macropus*: Fong and Del Castillo 2002. Herpetol. Rev. 33:205–206; *L. schreibersi*: Jenssen et al. 1989. Anim. Behav. 38:1054–1061); however, this appears to be the first observation of *Leiocephalus* eating dead lizards. Our observation suggests that *L. psammodromus*, and perhaps other species, may be opportunistic scavengers as well as predators.

The *L. psammodromus* (UF32893) was deposited in the herpetological collection at the Florida State Museum, University of Florida.

PHRYNOSOMA MCALLII (Flat-tailed Horned Lizard). **HIBERNATION**. Based on a study of captive animals in laboratory and outdoor enclosures, *P. mcallii* have been described as obligate hibernators, with a date of entry into hibernation varying from October to December (Mayhew 1965. Comp. Biochem. Physiol. 16:103–119). As part of a study to determine the effects of off-highway vehicle use on *P. mcallii*, in which a treatment of off-highway vehicles was applied to sites in November or December of 2004 (Grant 2005. MSc Thesis, Colorado State Univ., Fort Collins, Colorado. 84 pp.; online at: http://www.warnercnr.colostate.edu/~doherty), we followed 36 *P. mcallii* equipped with radio-transmitters into hibernation.

Lizards were at four study sites in the Colorado Desert, a subsection of the Sonoran Desert, in southern California. Twelve lizards were on East Mesa of the Imperial Valley (32°49'20"N, 115°15'10"W, datum: NAD83; elev. 10–15 m), 2 lizards on the Navy Parachute Range of West Mesa of the Imperial Valley (32°51'30"N, 115°46'20"W, datum: NAD83; elev. -5 to -10 m), 12 lizards were at Ocotillo Wells State Vehicle Recreation Area near Squaw Peak (33°10'50"N, 116°07'05"W, datum: NAD83; elev. 55–65 m), and 10 lizards were also at Ocotillo Wells State Vehicle Recreation Area a few miles north on the Pole Line Road (33°09'50"N, 115°59'30"W, datum: NAD83; elev. 25–65 m). A lizard was defined as hibernating if it was in a typical hibernation burrow (see below).

As in the captive study, free-ranging *P. mcallii* began hibernation from early October to late December. However, two lizards were never observed hibernating, although one of these was seen digging a burrow on 20 December. Five additional lizards abandoned their first hibernation burrows and moved to new hibernation burrows before we applied the experimental treatment in late November–December. These five *P. mcallii* moved < 10 m before digging a new burrow. Another two lizards were observed in a hibernation burrow at least once, but were on the surface and not in hibernation burrows when the treatment was applied to these areas in late December. *Phrynosoma mcallii* may be obligate hibernators, but their behavior seems variable.

Typical hibernation burrows were shallow and the entrance was plugged with substrate, whereas non-hibernation burrows, used daily in the summer, are not plugged and usually much longer and deeper. Upon excavation from a hibernation burrow, a lizard was usually (80% of the time [N = 27]) facing outward rather than into the burrow. We recorded hibernation depth (measured to the center of a lizard's dorsum) for 31 lizards. Median depth was 5.0 cm; mean depth was 6.0 cm (SE = 0.6, range 2–17). Only two lizards hibernated at depths > 10 cm. Summer burrows have been reported as being typically 70–80 cm long and 25–30 cm deep (Young and Young 2000. Final report: scientific study of the flat-tailed horned lizard, *Phrynosoma mcallii*. U.S. Dept. of Navy Contracts N68711-95-LT-C0032, N68711-95-LT-C0035. 72 pp.; Online at: http://bioweb.usu.edu/flattailweb).

We hypothesized that lizard mass might affect the date that lizards enter into hibernation. For 24 *P. mcallii* for which we measured their mass within 5 days of October 1, we regressed mass on date of entry into hibernation (Fig. 1). Because lizards were not relocated every week, date of entry into hibernation could only be resolved to within an 11–day interval. The middle date of that interval was estimated to be the hibernation date. This regression has a significant (non-zero) slope (β) of -4.3 (95% CI: -2.6 and -6.0; P = 0.000025). These results indicate that the smaller *P. mcallii* are, the more they delay hibernation, perhaps either to continue to grow or gain fat reserves for hibernation. Larger pre-hibernation mass has been found to be correlated with increased hibernation survivorship in other reptiles (e.g., *Thamnophis elegans*; Bronikowski 2000. Evolution 54:1760–1767).

We have few data for juvenile *P. mcallii* (< 65 mm SVL) because they were too small to carry radio-transmitters. On 18 November, we observed a juvenile (44 mm SVL) *P. mcallii* surface active, but we also found another juvenile (45 mm SVL) in a burrow with a plugged entrance, facing out, i.e. in typical hibernation position. On the warm days of 15 and 20 December, we observed 3 active juvenile *P. mcallii* (40–42 mm SVL); one was next to an

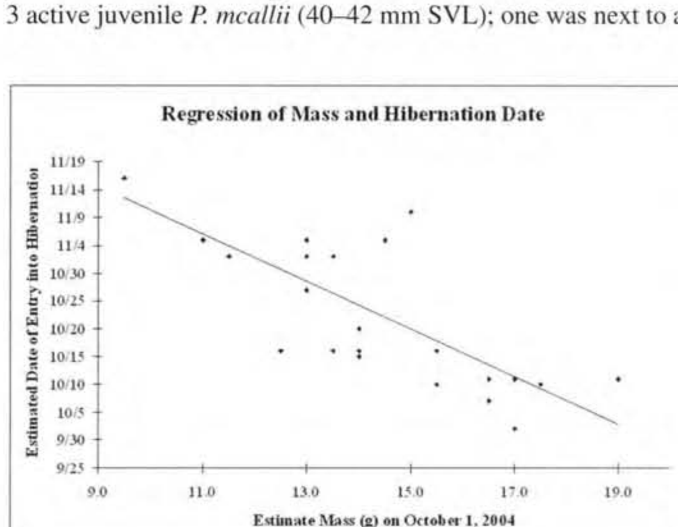

FIG. 1. Estimated mass on 1 October 2004 and estimated hibernation date of 24 *Phrynosoma mcallii* on three sites in southern California in 2004. The regression line of a linear estimate of the relationship between mass on 1 October 2004 and the estimated date of entry into hibernation (see text for details).

ant colony. It has been hypothesized that juveniles may not hibernate or that they hibernate for only a short time because they can reach reproductive size the following summer (Young and Young, *op. cit.*; Muth and Fisher 1992. Development of baseline data and procedures for monitoring populations of the flat-tailed horned lizard, *Phrynosoma mcallii*. Contract Report FG9268 to the Calif. Dept. Fish and Game, Sacramento, California.). Our observations suggest that juveniles can also be flexible in their hibernation habits.

The Bureau of Land Management, Department of the Navy, Bureau of Reclamation, and U.S. Fish and Wildlife Service provided support for this project. The California Department of Fish and Game approved a scientific collecting permit. Daniel Steward, Lynette Elser, and Chris Knauf at the Bureau of Land Management in El Centro, CA supported this project. Erin Dreyfuss, Christi Duncan, Brent Eastty, Angela Hyder, Darren Kelly, Justin Nobel, and Amanda Trahan assisted with field work.

PHRYNOSOMA TAURUS (Mexican Horned Lizard). **DEFENSIVE BEHAVIOR.** As horned lizards (genus *Phrynosoma*) are potential prey for many animals, they need effective defenses. Recently, field encounters between humans and each of several species of *Phrynosoma* were combined with controlled encounters with predators and literature records to determine which of the 13 currently recognized *Phrynosoma* species (including *P. taurus*) exhibit the anti-predator blood-squirting behavior (Sherbrooke and Middendorf 2001. Copeia 2001:519–527). Sherbrooke and colleagues (2004. Herpetol. Rev. 35:345–347) indicated that the only literature report of blood squiring in *P. taurus* was based on a misidentification of the species not based on personal observation (see Ruthling 1919. Copeia [72]:67–68). Thus, they concluded that the report of blood squirting by *P. taurus* was erroneous. We provide an observation of blood-squirting behavior in *P. taurus* that may require reconsideration of their conclusion.

In May 2005, while walking on a trail toward Sierra de Monteflor in Zoquiapan Boca de Los Ríos within the Biosphere Reserve of Tehuacan-Cuicatlan, Oaxaca, México, UOGV collected a male *Phrynosoma taurus* (80 mm SVL) at (17°36'38.3"N, 96°49'23.5"W, datum: WGS84; elev. 1374 m). The lizard was found while walking on a trail in an oak forest. When captured, the animal displayed the blood-squirting defensive behavior by ejecting blood from the sinus of the left eye. Execution of the behavior was rapid and occurred within 7 sec of handling. This record confirms the presence of blood-squirting behavior in *P. taurus*, and represents the first record of this behavior in response to a field encounter with humans.

Because the *P. taurus* occurred in a Biosphere Reserve, we photographed the animal for a voucher and then released it. The color slide voucher (MZFC 1598) was deposited in the herpetological collection of Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México, México.

Support for field work was provided by grant from CONABIO (number BK018) to G. Gutierrez-Mayén. We thank C. Villar-Salazar, D. Aportela, J. L. Aguilar-López and C. Hernández-Jiménez for assistance in the field and E. Perez-Ramos for his help in the identification and cataloguing the slide record.

Submitted by **URI OMAR GARCÍA-VÁZQUEZ** and **LUIS CANSECO- MARQUEZ,** Museo de Zoología, Facultad de Ciencias, UNAM, A.P. 70-399, México D.F. 04510, México (e-mail: urigarcia@gmail.com).

TUPINAMBIS MERIANAE (Tegu). **DIET**. The seven recognized species of tegu (genus *Tupinambis*) occur over a broad range habitats from forest to grassland. As adults, tegus are usually assumed to prey largely on small vertebrates and invertebrates (Zug et al. 2001. Herpetology: An Introductory Biology of Amphibians and Reptiles, 2nd edition. Academic Press, London. 630 pp.). However, dietary studies indicate that they are opportunistic omnivores that scavenge and include vegetable matter in their diets (Sazima and Haddad 1992. *In* Morellato [ed.], Historia Natural da Serra do Japi, pp. 212–235. Unicamp Press, Brazil). Here, we describe an unusual attempted predation event by *T. merianae* from southeastern Brazil.

At 1130 h on 30 December 2005, we observed an adult (ca. 50.0 cm SVL) *Tupinambis merianae* biting a juvenile (30.0 cm total length) armadillo (*Dasypus novemcinctus*) on Anchieta Island in the southeastern coast of Brazil (23°32'27.2"S, 45°03'57.1"W, datum: WGS84; elev. 6 m). The armadillo had a bruise on his dorsum (Fig. 1) that had an offal-like smell.

The predation attempt likely failed because the thickest part of the armadillo appeared to be too large to be swallowed. The offal-like smell from the armadillo's bruise may have triggered the predatory attempt, as scavenging on dead animals has been reported for *T. merianae* (Haddad and Sazima, *loc. cit.*).

FIG. 1. *Dasypus novemcinctus* with a bruise on the dorsum prior to its sustaining a predation attempt by *Tupinambis merianae*.

UROSTROPHUS VAUTIERI (NCN). **SKIN SHEDDING.** For many reptiles, ecdysis can make them temporarily more vulnerable to predation or can reduce their ability to feed. Lizards often rub their old skin on the substrate using their forelegs, hindlegs, mouth, and tail in what appears to be a series of creeping movements (Sousa et al. 2000. Revista Brasiliera Zool. 17:225–228). Ecdysis in most lizards involves loss of patches of skin, whereas ecdysis in snakes and some lizards (e.g., anguids) involves loss of the entire skin in one piece (Smith 1946. Handbook of Lizards: Lizards of the United States and of Canada. Comstock Publishing Co., New York. 557 pp.; Zug 1993. Herpetology: An Introductory Biology of Amphibians and Reptiles. Academic Press, San Diego, California. 527 pp.; Borges 1999. Serpentes Peçonhentas Brasileiras: Manual de Identificação, Prevenção e Procedimentos em Caso de Acidentes. Editora Atheneu, São Paulo. 148 pp.). Complete shed skins of snakes and anguids can often be used to identify species. We describe, for the first time, behavior of the leiosaurid lizard *U. vautieri* during a shedding event.

A single *U. vautieri* (95 mm SVL, 2.7 g) was captured in a pitfall trap on 26 September 2000, in a forest patch next to CBR - Centro de Biologia da Reprodução (Center of Reproduction Biology) at the Campus of Universidade Federal de Juiz de Fora – UFJF (21°46'50.5"S, 43°22'30.3"W, datum: WGS84; elev. 948 m). The lizard was maintained and observed in a terrarium (110 × 40 × 40 cm), enriched with a substrate of sand, rocks, dry leaves, and branches of different diameters distributed in different positions to provide perches. Mealworm larvae (*Tenebrio* sp.) were offered as food. Shedding behaviors were recorded and photographed.

At 0900 h on 3 October 2000, LBR found the *U. vautieri* in the initial stages of shedding its skin. Ecdysis began with a splitting of skin around the eyes and a dorsal split in skin extending from the back of the head to the distal portion of the posterior torso. During this process, the lizard kept crawling and rubbing its skin on a leaning branch with the back of its torso until the old dorsal skin was entirely removed. However, old skin still remained attached to its head, neck, limbs, and tail. The skin fragments remaining on the head were rubbed off on the branch and the lizard ate the detached pieces. Next, the lizard crawled up and down on the branch, which detached all skin on limbs and the belly. While it rubbed its skin on the branch, the lizard searched its body for detached skin, and, at 1–2 minute intervals, it swallowed pieces that had been removed. To remove the skin remaining on its tail, the lizard bit the skin at the base of the tail and pulled on it. It then detached its old skin from the base to the end of its tail by turning its body in circular movements. The entire shedding process required ca. 40 min.

The shedding skin process in *U. vautieri* we observed was similar to that observed by Sousa et al. (*op. cit.*) for *Enyalius perditus* and *E. bilineatus* of the same family. In *E. perditus*, however, the lizard's initial skin detachment, occurred transversely on the dorsal part of the head, between the tympana.

The *U. vautieri* (CH-UFJF 051) was deposited in the herpetological collection of Universidade Federal de Juiz de Fora, Juiz de Fora City. We thank Laurie J. Vitt and reviewers for helpful comments on a first draft of the manuscript.

VARANUS EREMIUS (Rusty Desert Monitor). **ENDOPARASITES.** *Varanus eremius* is a small (adults ca. 50 cm total length) monitor known from central coastal regions of Western Australia to desert areas of South Australia and the Northern Territory (Cogger 1996. Reptiles & Amphibians of Australia, 6th ed., Ralph Curtis Publications, Sanibel Island, Florida. 808 pp.). Two previous reports of helminths for *V. eremius* exist: both reported larvae assigned to the nematode family Physalopteridae (Jones 1995. Aust. J. Zool. 43:141–164; Jones 1995. J. Wild. Dis. 31:299–306). The purpose of this note is to report one species of Cestoda and two species of Nematoda in *V. eremius*.

Coelomic cavities and small and large intestines of 20 *V. eremius* (mean SVL = 124 mm ± 12.4 SD, range: 105–1148 mm) from Western Australia collected between 119°05'E to 123°55'E and 26°14'S to 28°27'S, datum: AGD66; elev. ca. 465 m during 1966–1968 in the herpetology collection of the Natural History Museum of Los Angeles County (LACM 54088–54091, 54094, 54096–54099, 54112, 54115–54116, 54119–54120, 54123–54124, 54126–54127, 54129–54130) were examined for helminths. Stomachs were unavailable for examination. Cestodes were regressively stained in hematoxylin, mounted in Canada balsam, studied as whole mounts and identified as *Acanthotaenia gracilis* (prevalence: infected lizards/lizards examined × 100 = 35%; mean intensity: mean number of helminths per infected lizard ± SD = 2.1 ± 1.2). Nematodes were cleared in a drop of concentrated glycerol on a glass slide, cover-slipped, and identified as *Kreisiella lesueurii* (prevalence: 15%, mean intensity: 5.3 ± 4.5) and *Maxvachonia brygooi* (prevalence: 40%, mean intensity: 6.8 ± 7.6). Helminths were deposited in the United States National Parasite Collection, Beltsville, Maryland: *Acanthotaenia gracilis* USNPC (97447); *Kreisiella lesueurii* USNPC (97448); *Maxvachonia brygooi* USNPC (97449).

Beddard (1913. Proc. Zool. Soc. London 1913:4–36) described *Acanthotaenia gracilis* from a *Varanus varius* collected in Australia. *Varanus eremius* is the second host reported to harbor this cestode. To our knowledge, the life cycles of species of *Acanthotaenia* are unstudied. *Kreisiella lesueurii* is known from Australian scincids and agamids (Goldberg and Bursey 2000. Trans. Roy. Soc. S. Aust. 124:127–133). *Maxvachonia brygooi* is known from Australian scincids, agamids and a varanid (Goldberg and Bursey, *op. cit.*). *Kreisiella leseueurii* is a member of the Physalopteridae which typically utilize insect intermediate hosts; *M. brygooi* belongs to the Cosmocercidae in which infection results from ingesting eggs (Anderson 2000. Nematode Parasites of Vertebrates: Their Development and Transmission, CABI Publishing, Wallingford, United Kingdom. 650 pp.). *Varanus eremius* repre-

sents a new host record for *Acanthotaenia gracilis*, *Kreisiella lesueurii* and *Maxvachonia brygooi*.

We thank Christine Thacker (LACM) for permission to examine *V. eremius*, and Dustin Goto and Sean Kark (Whittier College) for assistance with dissections.

XENOSAURUS RECTOCOLLARIS (Pallid Knob-scaled Lizard). **PARENTAL CARE**. Parental care is infrequent in reptiles (Wesolowski 1994. Am. Nat. 143:39–58), although it exists in some lizards (Somma 1987. Great Basin Nat.47:536–537). In *Xenosaurus newmanorum*, an association between females and neonates exists that may indicate parental care (Lemos-Espinal et al. 1997. Herpetol. Rev. 28:22), but no observations of similar behavior exist in other *Xenosaurus*. Hence, we report observations implying parental care in the rock-crevice dwelling *X. rectocollaris* (Ballinger et al. 1995. Biotropica 27:128–132), a species endemic to the Biosphere Tehuacán-Cuicatlán Reserve that inhabits arid zones with little vegetation at elevations up to 2000 m (Lemos-Espinal et al. 1996. Herpetol. Nat. Hist. 4:151–154).

During a mark-recapture study of this species in 2004, we observed nine occasions where a female and one or two neonates occupied one crevice. The first occasion occurred on 7 April. In a crevice 8 mm wide × 150 mm deep, and 39 mm above the ground, we observed a female (89 mm SVL) with a juvenile (54 mm SVL). On 8 April 2004, we observed two more associations; one was in a crevice 11 mm wide × 145 mm deep, and 300 mm above the ground that contained a female (102 mm SVL) and one juvenile (57 mm SVL). The other was in a crevice 8 mm wide × 100 mm deep, and 220 mm above the ground, and contained a female (100 mm SVL) with one juvenile (63 mm SVL).

On 7 May 2004, we observed a female (102 mm SVL) with two juveniles (52 and 51 mm SVL) in a crevice 9 mm wide × 91 mm deep, and 100 mm above the ground, The females and juveniles marked in April were still in their same crevices.

In mid-July 2004, a female (105 mm SVL) was found with a juvenile (60 mm SVL) in a crevice 8 mm wide × 160 mm deep at ground level. Lizards marked in April and May were still inside their same crevices.

On 17 September 2004, we found a gravid female (100 mm SVL) with two juveniles (51 and 65 mm SVL, respectively) in a crevice 10 mm wide × 200 mm deep, and 240 mm above the ground. The next day, we observed three associations: a female (103 mm SVL) with a juvenile (50 mm SVL) in a crevice 8 mm wide × 170 mm deep at ground level; a female (87 mm SVL) and a juvenile (47 mm SVL) in a second crevice 10 mm wide × 650 mm deep, and 1500 mm above the ground; and a female (103 mm SVL) and a juvenile (51 mm SVL) in a third crevice 21 mm wide × 160 mm deep at ground level. The animals noted in previous months were still in the same positions as before.

In all instances, juveniles were innermost in their crevices. The outermost position of the females may have been a protective behavior, or simply due to the size differential of the crevices. Manipulative study will be necessary to determine whether these associations really reflect parental care.

SERPENTES

ALSOPHIS CANTHERIGERUS (Jubo, Jubo de Sabana, Jubo Sabanero). **SIZE RECORD.** On 25 June 1926, Charles T. Ramsden collected a female *Alsophis cantherigerus* from San Carlos, Guantánamo Province, Cuba. This specimen (CTR without number; "Charles T. Ramsden" historic collection deposited at Instituto de Ecología y Sistemática, Cuba) was determined as *A. c. pepei* by MD on 3 March 2005. It measures 1333 mm snout–vent length, 480 mm tail length (tail incomplete), and according to Ramsden's notes, there were 58 eggs in the oviducts. The previously reported maximum SVL for this species was 1220 mm (Schwartz and Henderson 1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. Univ. Florida Press, Gainesville, xvi + 720 pp.). Novo and Arazoza (1986. Rep. Inv. 30:1–15) reported maximum clutch size for this species as 24 eggs for a female measuring 1160 mm SVL, and noted a positive correlation between clutch size and SVL.

Submitted by **MICHEL DOMÍNGUEZ** (e-mail: michel.dominguez@ecologia.cu, micdom2002@yahoo.es) and **LUIS V. MORENO**, División de Colecciones Zoológicas, Instituto de Ecología y Sistemática, Carretera de Varona km 3 1/2, Capdevila, Boyeros, A.P. 8029, C.P. 10800, Ciudad de La Habana, Cuba.

BOIRUNA MACULATA (Mussurana, Víbora luta, Mamona). **PREY AND PREDATION BEHAVIOR.** *Boiruna maculata* has a large distribution in southern South America, from Mendoza, southwestern Argentina to southern Bolivia, western Mato Grosso do Sul and southern Goiás, and southern Brazil. It is also found in Paraguay and Uruguay (Achával and Olmos 1997. Anfibios y Reptiles del Uruguay. Olmos Editor. Montevideo, Uruguay. 128 pp.; Giraudo and Scrocchi 2002. Smithson. Herpetol. Infor. Serv. 132, 53 pp.; Zaher 1996. Boll. Mus. Reg. Sc. Nat. Torino 14[2]:289–337). Because of its distribution, coloration, food habits, and myths about its behavior, the species is one of the best known in the region.

In spite of this, here we describe a previously unreported behavior and prey species. On 10 January 2004 at 0030 h, while conducting a herpetological survey in the Reserva Ecológica El Bagual (26°10'53"S, 58°56'39"W; datum WGS84, Formosa, Argentina, we observed an adult bird, known locally as a "Zorzal colorado" (*Turdus rufiventris,* Turdidae), fall from its nest in an "Espina Corona" tree (*Gleditsia amorphoides*) at 1.5 m above

ground. We observed a male *Boiruna maculata* (SVL 1298 mm; 525 g; herpetological collection Fundación Miguel Lillo, Tucumán, Argentina, FML 15421) climb the tree and eat one of the three chicks (45.0 g; 39.5 g, and 40.3 g; ca. 9 days old) in the nest.

On 18 November 1996, another *B. maculata* was captured during the morning, resting in a nest of "Boyero ala amarilla" (*Cacicus chrysopterus,* Icteridae) that was hanging at the end of a thin branch of a "Guayacán" (*Caesalpinia paraguayensis*) at 3.5 m from the ground and 5 m from the trunk; the snake regurgitated two chicks and in the nest we found two others, one dead and another alive (estimated age and weight of the chicks: 16–18 days; 30–34 g). Another snake from the same locality (FML 11560, female, SVL 1180 mm) contains a slightly digested chick (86 g, 160 mm TL; estimated age 7 days) of "Chajá" (*Chauna torquata,* Anhimidae) in its stomach.

Previous reports about the feeding habits of *Boiruna maculata* mention snakes, lizards, mice, and fishes in the diet (see Carreira Vidal 2002. Alimentación de los Ofidios de Uruguay, Monografías de Herpetología, Vol. 6. Asociación Herpetológica Española. Barcelona, España, 126 pp. and literature cited therein). Our observations indicate that *B. maculata*, at least at this locality, habitually feeds on nestling birds, and climbs trees in search of nests and chicks, in spite of its stout body and relatively short tail—a body form typical of ground-dwelling species.

BUNGARUS MULTICINCTUS MULTICINCTUS (Many-Banded Krait). **DIET**. *Bungarus m. multicinctus* mainly feeds on fish, frogs, skinks, snakes, and mice (Mao 1993. Common Terrestrial Venomous Snakes of Taiwan. National Museum of Natural Science Spec. Publ. No. 5). Larger *B. m. multicinctus* tend to be more ophiophagous (Mao 1970. Herpetologica.26:45–48), with the following species recorded as prey: *B. m. multicinctus*, *Enhydris plumbea*, *Ramphotyphlops braminus*, *Cyclophiops major*, *Trimeresurus stejnegeri*, *Xenochrophis piscator* (Lin et al. 1995. NOW 3[2]:19–21 [in Chinese]; Mao 1970, *op. cit.*; Mao, pers. obs.).

At 1955 h on 5 May 2005, in Da-jiou-shi Experimental Forest, National Ilan University, northern Taiwan, we observed a male *B. m. multicinctus* (ca. 110 cm total length) subduing a Taiwanese Habu (*Protobothrops mucrosquamatus*) (ca. 65 cm total length) on the roadside of the forest nursery trail (24°47'11"N, 121°40'39"E; 254 m elev.). The air temperature was 22.6°C and the relative humidity was 68%.

When attacked, the *P. mucrosquamatus* bit the *B. multicinctus* on its back. Because a drop of blood was visible on the dorsal scales, we assume that the fang penetrated the skin of the *B. multicinctus*. However, we observed no changes in the behavior of the *B. multicinctus*. After the *P. mucrosquamatus* stopped struggling, the *B. multicinctus* started to swallow it headfirst. At 2115 h the prey was completely swallowed, and the *B. multicinctus* moved to a nearby bamboo bush. To our knowledge, this is the first report of *P. mucrosquamatus* being preyed upon by a *B. m. multicinctus*.

CROTALUS INTERMEDIUS GLOYDI (Oaxacan Small-headed Rattlesnake). **DIET.** *Crotalus intermedius* is a small, montane species known to prey only on lizards. Klauber (1972. Rattlesnakes: Their Habits, Life Histories, and Influence on Mankind. 2nd ed. Univ. California Press, Berkeley, California. 1533 pp.) found two large lizards (unidentified species) and lizard scales in three specimens of *C. i. intermedius*, and a lizard (unidentified species) and lizard scales in 12 *C. i. omiltemanus*. Campbell and Armstrong (1979. Herpetologica 34:304–317) reported finding *Sceloporus* scales in the scats of 18 *C. i. omiltemanus* from Guerrero and *Sceloporus* remains in the stomachs of several *C. i. gloydi* from Oaxaca. Campbell and Lamar (2004. Venomous Reptiles of the Western Hemisphere. Cornell Univ. Press, Ithaca, New York. 870 pp.) further reported finding *S. formosus* and *S. mucronatus* in the stomachs of *C. i. omiltemanus* from Guerrero.

On 25 June 2005 Boone Hallberg presented us with a collection of preserved reptiles from his property ca. 3 km E of Ixtlán de Juárez in Oaxaca, Mexico. Among these specimens was a juvenile *C. i. gloydi* with a noticeable bulge in its stomach. Upon dissection we found that the snake (SVL 225 mm, mass 9 g) had ingested a large mouse (*Reithrodontomys fulvescens helvolus*; snout

FIG. 1. Juvenile *Crotalus intermedius gloydi* and the prey item (*Reithrodontomys fulvescens helvolus*) it consumed; the approximate prey/predator mass ratio was 1.4.

to rump length 80 mm, tail length 72 mm, mass 13 g) head-first. The approximate prey/predator mass ratio was 1.4. The snake and the mouse were accessioned together in the herpetological collection of the Instituto Tecnológico Agropecuario de Hidalgo (ITAH 1331).

We thank Boone Hallberg for donating the specimen and for allowing us access to his property; Steve Mackessy, Mike Torrocco, Griselda Quijano, Arisay Melo, and Ray Queen for assistance in the field; and Javier Rodríguez and Jonathan Campbell for reviewing the manuscript. Research and collecting were conducted under the authority of SEMARNAT scientific research permits OFICIO NÚM/SGPA/DGVS/02100 issued to FMQ and RWB.

GEOPHIS HOFFMANNI (Hoffmann's Earth Snake). **REPRODUCTION.** *Geophis hoffmanni* is known from eastern Honduras to central Panama and Costa Rica (Savage 2002. The Amphibians and Reptiles of Costa Rica. A Herpetofauna Between Two Continents Between Two Seas, Univ. Chicago Press, Chicago, Illinois, 934 pp). There are reports of clutches of up to five eggs (numbers of individual clutches not given) from November and December in Solórzano (2004. Snakes of Costa Rica. Distribution, Taxonomy, and Natural History, Instituto Nacional de Biodiversidad, INBio, Santo Domingo de Heredia, Costa Rica, 791 pp.). The purpose of this note is to report additional clutch sizes by month for *G. hoffmanni* from Costa Rica.

I examined ten females (mean snout–vent length, SVL = 225 mm ± 17 SD, range: 201–255 mm) from the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California: LACM: 151179, 151188, 151202–151204, 151215, 151216, 151221, 151232, 151233. Nine *G. hoffmanni* were from San José Province one was from Heredia Province. They were collected 1963, 1966, 1983. The left ovary was removed, dehydrated in ethanol and embedded in paraffin. Histological sections were cut at 5 μm and stained with Harris' hematoxylin followed by eosin counterstain. Enlarged ovarian follicles (> 8 mm length) or oviductal eggs were counted; no histology was done on them.

Eight of the ten females contained enlarged follicles or oviductal eggs and were from: June (N= 1), August (N = 1), September (N = 1), October (N = 1), November (N = 4). Mean clutch size (N = 8) was 2.6 ± 0.52 SD, range: 2–3. One female from November was undergoing yolk deposition (= secondary vitellogenesis *sensu* Aldridge 1979. Herpetologica 35:256–261) for a subsequent clutch and another from November was not undergoing yolk deposition. The smallest reproductively active female (3 oviductal eggs) measured 201 mm SVL (LACM 151215) and was from June. The presence of reproductively active females over a six month period (including December from Solórzano, *op. cit.*) indicates a prolonged ovarian cycle with the likelihood of multiple egg clutches produced in the same year. *Geophis brachycephalus* from Costa Rica produced egg clutches during January, February, July, August, October, November (Sasa 1993. Rev. Biol. Trop. 41:295-297) also indicating an extended ovarian cycle.

I thank C. Thacker (LACM) for permission to examine specimens. Specimens are from the CRE collection donated by J.M. Savage to LACM.

Submitted by **STEPHEN R. GOLDBERG,** Department of Biology, Whittier College, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu).

GEOPHIS SEMIDOLIATUS (Coral Earth Snake). **REPRODUCTION.** *Geophis semidoliatus* is known from Veracruz and Puebla, Mexico (Downs 1967. Misc. Publ. Mus. Zool. Univ. Michigan 131:1–193; Canseco-Marquez et al. 2000. Herpetol. Rev. 31:259–163). To my knowledge, there is no published information on its reproduction. The purpose of this note is to provide information on the reproductive cycle of *G. semidoliatus* based on a histological examination of gonads from museum specimens.

I examined ten females (mean snout-vent length, SVL = 256 mm ± 12 SD, range: 237–277 mm), seven males (SVL = 222 mm ± 19 SD, range: 190–241 mm) and three neonates (SVL = 114 mm ± 5 SD, range: 108–118 mm) from the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California: LACM 2547, 122136, 122203–122207, 122212, 122213, 122217, 122221, 122224, 122226, 122228–122230, 122275, 122277–122279. All *G. semidoliatus* were from Veracruz, Mexico and were collected in 1969, 1971, or 1972. The left testis and vas deferens or ovary was removed, dehydrated in ethanol and embedded in paraffin. Histological sections were cut at 5 μm and stained with Harris' hematoxylin followed by eosin counterstain. Enlarged ovarian follicles (> 8 mm length) or oviductal eggs were counted; no histology was done on them.

Spermiogenesis was in progress in the seven males examined. The vas deferens from each male contained sperm. All were from July. The smallest male measured 190 mm SVL. The ten females were all reproductively active (enlarged follicles or oviductal eggs) and were from: July (N = 6), August (N = 1), September (N = 2), October (N = 1). One July female with oviductal eggs (LACM 122224) was undergoing concurrent yolk deposition (= secondary yolk deposition *sensu* Aldridge 1979. Herpetologica 35:256–261) for a subsequent clutch indicating *G., semidoliatus* may produce more than one clutch in the same year. Mean clutch size (enlarged ovarian follicles or oviductal eggs was 2.1 ± 0.7 SD, range: 1–3 eggs). These are the first clutch sizes reported for *G. semidoliatus.* The smallest reproductively active female measured 237 mm SVL (enlarged ovarian follicles). Three presumably neonates were collected during summer: LACM 122279, SVL = 108 mm and LACM 122226, SVL = 118 both from July and LACM 122136, SVL =115 from August.

I thank C. Thacker (LACM) for permission to examine specimens.

Submitted by **STEPHEN R. GOLDBERG,** Department of Biology, Whittier College, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu).

HETERODON PLATIRHINOS (Eastern Hognose Snake). **ROAD CROSSING BEHAVIOR**. The effect of roads on the ecology and movement patterns of animals is of great interest to ecologists and conservationists (Forman and Alexander. 1998, Ann. Rev. Ecol. Syst. 29:207–231; Forman et al, 2003, Road Ecology: Science and Solutions, Island Press, Washington, D.C.). Recent work on snakes demonstrates that roads might have significant effects on their movements (Shine et al. 2004. Ecology and Society 9:9). Furthermore, different species of snakes may respond differently to roads (Andrews 2003. Proc. Int. Conf. Ecol. Trans., pp. 649–651; Andrews and Gibbons 2005. Copeia 2005:772–782).

In the course of accumulating over 1700 observations while radiotracking 16 *Heterodon platirhinos* daily over four years (Plummer and Mills 2000. J. Herpetol. 34:565–575), we observed 61 cases among four snakes that approached within 5 m of a lightly used 5 m wide paved asphalt road. In each case, we recorded the snake's location the following day and classified the interim movement as a 1) road crossing; 2) a move away from the road (snake reversed its direction of travel); or 3) a move parallel to the road. Three snakes approached the road 27 times but avoided crossing (Table 1). One male snake (HP6) appeared to move randomly after approaching the road, crossing it in 25% of cases. Eight of his nine crossings resulted from moving to and from a hibernaculum on the side of the road opposite from its home range (Plummer 2002. Herpetol. Rev. 33:89–90) and occurred at two specific locations on the road. Among all snakes, only 15% of the 61 road approaches were followed by crossings. Our telemetric data suggest that *H. platirhinos* is sensitive to the presence of paved roads and that moving individuals typically avoid crossing them; however, some individuals might be compelled to cross when moving to and from hibernating sites (Bonnett et al. 1999. Biol. Cons. 89:39–50). The overall 85% avoidance rate we found is similar to the 80% road avoidance rate observed for *H. platirhinos* by Andrews and Gibbons (*op. cit.*). Plummer and Mills (*op. cit.*) found that resident *H. platirhinos* moved about 120 m per day within unusually large (50 ha) home ranges, probably creating regular opportunities for road crossings on the study area. That crossings did in fact occur is evidenced by HP6 and by two road-killed untracked *H. platirhinos* observed over four years of daily observations.

TABLE 1. Number of responses of *Heterodon platirhinos* after approaching a paved asphalt road. Responses were classified as road crossings, movements away from the road, and movements parallel to the road.

Snake	Sex	No. approaches	No. crosses	No. away	No. parallel
HP1	F	6	0	3	3
HP6	M	34	9	9	16
HP10	F	16	0	1	15
HP13	M	5	0	2	3
Total		61	9 (14.8%)	15 (24.6%)	37 (60.7%)

HETERODON PLATIRHINOS (Eastern Hognose Snake). **REGURGITATION OF PREY.** The death-feigning behavior of snakes in the North American genus *Heterodon* has long been recognized (Edgren. 1955. Herpetologica. 11:105–117). On 11 September 2005, in the Adirondack foothills of northwestern Saratoga County, New York, USA, JB encountered an active neonate *H. platirhinos* (ca. 11.4 cm TL). During an attempt to move the snake, it responded by hissing, hooding, and writhing. As the snake entered the death-feigning phase, it regurgitated a partially digested red eft (land stage of *Notophthalmus viridescens*). After the death-feigning phase was completed, the snake retreated. Although predation on *N. viridescens* by *H. platirhinos* has been reported (Uhler et al. 1939. Trans. N. Am. Wildl. Conf. 4:605–622), we are unaware of reports indicating predation frequency. Tetradotoxin (TTX) and its analogues occur in many terrestrial and marine animals and have been detected in salamanders of the genera *Taricha*, *Notophthalmus*, *Cynops*, *Ambystoma*, *Triturus*, and *Paramesotriton* (Yamashita and Mebs 2001. Toxicon 39:1261–1263). Brodie et al. (1974. Copeia 1974:506–511) found that the aposematically pigmented red eft stage of *N. viridescens* contained concentrations of TTX approximately ten times the levels of the aquatic adult stage. Further observations are needed to determine if *Heterodon platirhinos* frequently predate red efts in the referenced area.

HETERODON PLATIRHINOS (Eastern Hognose Snake). **ENVENOMATION AND PREY SURVIVAL.** Whether or not colubrid snakes of the genus *Heterodon* are at all venomous has been questioned, but mostly supported since the idea was first proposed by Ditmars (1912. Zoologica 1:204) upon observation of microscopic grooves along the rear fangs. Later, evidence was provided through personal experiences and observations of envenomation by *Heterodon*, first by Bragg (1960. Herpetologica 16:121–124) and later by Grogan (1974. Herpetologica 30:248–249) and Morris (1985. Herpetologica 41:361–363). Each author described swelling and pain at the site of the wound. Hill and Mackessy (1997. Toxicon 35:671–678; and 2000. Toxicon 38:1663–1687; see also Mackessy 2002. J. Toxicol.-Toxin Rev. 21:43–83 for an extensive review of toxicity of colubrid salivas) used molecular techniques to quantify the toxicity and enzymatic activity in venoms of several species of colubrid snakes (including subspecies within *H. nasicus*). However, experimental evidence supporting toxicity of *Heterodon* saliva is limited. In one study, fluid from the salivary glands of *H. platirhinos* was injected into mice (none died), anurans (15 of 17 died; including *Bufo fowlerii,* 8 of 10 died), and one *Ambystoma laterale* (which did not die) (McAlister 1963. Herpetologica 19:132–137). Additionally, Young (1992. Toxicon 30:775–779) showed that application of *H. platirhinos*

Duvernoy's gland secretion caused pronounced reduction of muscle twitch amplitude during frog (*Rana pipiens*) neuromuscular preparations, but in guinea pig and rat tissue preparations effects were considerably less. Injection of Duvernoy's gland secretion into mice caused initial hyperactivity and later lethargy. We avoid use of the word "venom" to refer to any components of saliva for reasons discussed by Kardong (1982. Mem. Inst. Butantan 46:105–188). While some of these accounts demonstrate the toxicity of *Heterodon* saliva, there is little evidence demonstrating its efficacy and use as an applied means of subduing or killing prey in the wild. Furthermore, some authors have proposed that *Heterodon* snakes use their rear fangs for "popping" toads (Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Inst. Press, Washington, DC, 680 pp.). This too remains largely unobserved in the field and is purely speculative.

Herein, we provide evidence that challenges the efficacy of the toxic capacity and fang-mediated puncturing ability in *Heterodon*. Our observations indicate that these physiological attributes may not function as reliable predatory mechanisms.

During a telemetry study of *H. platirhinos* at the Brookhaven National Laboratory, Upton, Suffolk County, New York, USA (40°52'20"N, 72°52'04"W) one of us (SEG) recorded mass and length for one of the snakes in our study at 1500 h on 22 July 2004. The snake (SVL = 730 mm, 399 g), clearly disturbed by these activities, regurgitated a live *Scaphiopus holbrookii* (SVL = 32.0 mm, 2.6 g). The toad was rinsed with water and placed in a secure enclosure where it lived for 42 days before it was released at the location of its collection. The toad appeared healthy and ate well on a diet of crickets while in captivity. The toad did not appear to show any detrimental effects as a result of being swallowed by the snake. Again, on 31 May 2005, one of us (JAF) observed a different *H. platirhinos* (SVL = 538 mm, 224 g) regurgitate a live adult *Bufo fowleri* (SVL = 50.4 mm, 19.1 g). The toad appeared completely healthy and was kept under observation for 12 h before being released. Two other reports of live regurgitation were observed by Wendy Finn (pers. comm.) during her participation as a technician on this study. One observation occurred on 23 June 2005 and involved a snake (SVL = 505 mm, 114 g) regurgitating an undetermined anuran species that quickly escaped. The final observation occurred on 7 July 2005 and involved the same snake from 31 May 2005 regurgitating another *B. fowleri* (SVL = 58 mm, 25 g). This toad was kept in observation for five days and then released. Thus, three snakes in total were observed regurgitating live anurans indicating that this is not a unique event confined to a single individual, but rather an occurrence that might happen regularly. As such, these findings suggest limitations to the overall efficacy of the predatory mechanisms that have been attributed to this species, specifically mildly venomous saliva and prey-puncturing rear fangs.

We thank S. P. Mackessy for helpful comments on this note.

LEPTOTYPHLOPS TENELLUS (Guyana Blindsnake). **PREDATION.** Hawks of the genus *Micrastur* are known to generally feed upon birds and insects (Robinson 1994. Biotropica 26:443–458). *M. ruficollis* is, however, also reported to feed on *Anolis* and other mainly arboreal lizards such as *Laemanctus* and *Corytophanes*, as well as larger actively foraging terrestrial lizards of the genus *Ameiva* (Thorstrom 2000. J. Raptor Res. 34:196–202). Additionally, snakes form the bulk of the diet for *M. gilvicollis* (del Hoyo and Sargatal 1994. Handbook of the Birds of the World, vol. 2. Lynx Edicions, Barcelona, 638 pp.). However, none of the *Micrastur* species has been reported to feed on small semi-fossorial or leaf-litter dwelling snakes or lizards. On 24 November 2005 an adult female *M. gilvicollis* (YPM ORN 101439) was collected by Jorge de Leon from the environs around Augustus Creek near the northern rim of Tafelberg Plateau, Sipaliwini District, Suriname. During specimen preparation two reptiles were removed from the stomach, *Leptotyphlops tenellus* (YPM R15355) and a gymnopthalmid lizard *Iphisa elegans* (YPM R15358). *Leptotyphlops* burrows and *Iphisa* forages under leaf-litter (Dixon 1974. Herpetologica 30:133–139; Hahn 1979. Cat. Amer. Amphib. Rept. 230:1–4) Robinson (*op. cit.*) and del Hoyo and Sargatal (*op. cit.*) report that *M. gilvicollis* has been observed following ants through the forest, but that generally it attacks from concealed perches in the understory. It has not previously been reported to feed on prey species that are mostly hidden from view beneath leaf litter. We present evidence that fossorial and semi-fossorial squamates are also taken by *M. gilvicollis* and suspect that such prey are probably encountered during ant-foraging behavior.

Submitted by **GREGORY J. WATKINS-COLWELL**, **JORGE DE LEON**, and **SUSAN B. HOCHGRAFF,** Division of Vertebrate Zoology, Yale Peabody Museum of Natural History, 170 Whitney Avenue, New Haven, Connecticut 06520, USA; e-mail (GJWC): Gregory.watkins-colwell@yale.edu.

PROTOBOTHROPS MUCROSQUAMATUS (Taiwanese Habu). **STOMACH CONTENTS.** *Protobothrops mucrosquamatus* is a dietary generalist, mainly feeding on frogs (*Rana limnocharis, R. longicrus*), snakes (*Amphiesma stolatum, A. sauteri*), birds, rodents (*Mus formosanus, Rattus losea, R. norvegicus, R. coxinga*), shrews (*Suncus murinus*; Mao 1970. Herpetologica 26:45–48), and white mice under laboratory conditions (Kuntz 1963. Snakes of Taiwan. U.S. Naval Medical Research Unit No. 2). Small mammals (rodents and insectivores) seem to be its principal prey (Mao, *op. cit.*), and we have observed these snakes ambushing bats in dark crevices and caves.

At 2245 h, on 10 May 2005, in Da-jiou-shi Experimental Forest (DEF; 254 m, 24°47'11"N, 121°40'39"E), National Ilan University (NIU), northern Taiwan, a female *P. mucrosquamatus* (330 mm snout–vent length, 75 mm tail length) was observed moving along a concrete barrier. The snake had a greatly enlarged midbody, which affected its mobility. Upon palpation, the snake regurgitated a Long-tailed Shrew (*Crocidura kurodai*), with a body

length, tail length, and body mass of 63 mm, 54 mm, and 6.5 g, respectively. The snake was then released where found.

Long-tailed Shrews and Tanaka Grey Shrews (*C. attenuata*) are sympatric and abundant in DEF (Mao, in prep.). On many occasions, we have observed shrews along the concrete barrier at night. Based on our observations, *Trimeresurus stejnegeri* (Bamboo Vipers) regularly ambush along the concrete barrier, and on some occasions, *P. mucrosquamatus* and *Bungarus multicinctus* (Many-banded Kraits) have been encountered. It seems probable that this artificial structure concentrates local prey species in a linear fashion and thereby offers a better opportunity for successful predation. To our knowledge, this is the first report of a *P. mucrosquamatus* preying on *C. kurodai*.

Submitted by **JEAN-JAY MAO**, Department of Natural Resources, National Ilan University, No. 1, Sec. 1, Shen-Lung Rd., Ilan, Taiwan 260 (e-mail: jjmao@niu.edu.tw); and **GERRUT NORVAL**, Applied Behavioural Ecology & Ecosystem Research Unit, Department of Nature Conservation, UNISA, Private Bag X6, Florida, 1710, Republic of South Africa.

PSEUDABLABES AGASSIZII (Burrowing Night Snake). **REPRODUCTION**. The monotypic genus *Pseudablabes* is endemic to the Neotropics, occurring from central Brazil to northwestern Argentina and Uruguay (Peters and Orejas-Miranda 1970. Catalogue of the Neotropical Squamata: Part I Snakes, Smithsonian Institution Press, Washington, D.C. 347 pp.). Information regarding this species is restricted to a few studies on morphology, habitat use, diel activity, diet, feeding behavior, reproduction, and seasonal activity. Our knowledge of clutch and egg characteristics is limited (see Marques et al., Herpetol. J., *in press*). Here, we provide data on clutch size, volume and mass of eggs, size of hatchlings, and incubation time for eggs from a wild-caught *P. agassizii*. The female was collected during the faunal rescue for the Hydroelectric Usine of Queimado (16°12'S, 47°19'W), on the frontier of Minas Gerais and Goiás states, and Distrito Federal, including the municipalities of Unaí, Cabeceira Grande (MG), Formosa, Cristalina (GO), and Região Administrativa de Paranoá (DF). UHE Queimado was built on the Preto River, São Francisco basin, where the most representative local macrohabitat is the Cerrado *sensu lato* (Rizzini 1979. Tratado de Fitogeografia do Brasil, Vol. 2, Editora da Universidade de São Paulo, São Paulo, 374 pp.). The gravid female was collected in the morning of 19 October 2003 (316 mm SVL, 103 mm TL; 149 mm head length; 0.65 mm head height; 0.66 mm head width, and 144 g total mass). She was kept in a ventilated wooden collection box (40 × 20 × 20 cm), at room temperature (varied approximately between 20–34°C night/day). The substrate was lined with soil and leaf litter. At 0700 h on 21 October 2003, we found nine eggs, adhered to one another, in the corner of the box (Fig. 1). The eggs were similar in size (mean length 19.07 mm ± 0.59 SD; mean width 11.45 mm ± 0.05 SD; Table 1). The eggs were moved to an artificial incubator, a plastic box (40 × 20 × 15 cm) with a clip lid. The substrate consisted on a 6 cm layer of vermiculite. The box was heated at night by two 40-W lamps. The temperature inside the box, measured twice a day with a mercury thermometer, varied between 26–31°C. Substrate moisture was also monitored, and when necessary, water was sprayed on the inner side of the box. Two days after oviposition, one egg dehydrated and was discarded. Hatching began on the morning of 16 December 2003 and continued to 18 December.

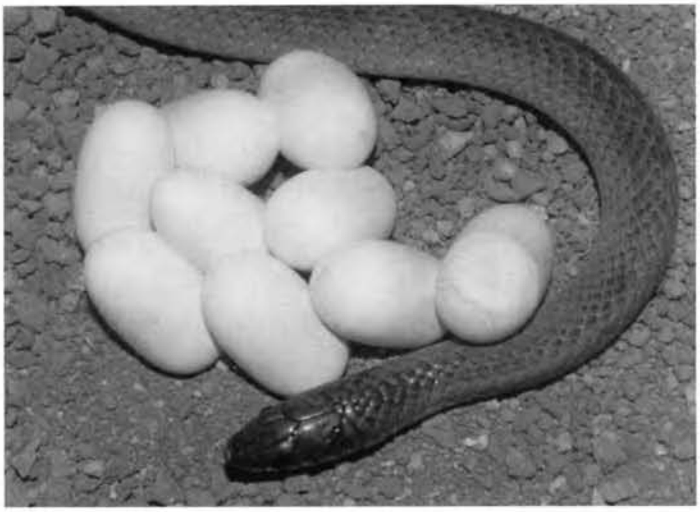

FIG. 1. Female *Pseudablabes agassizii* and its eggs (Minas Gerais, Brazil).

TABLE 1. Measurements of female and hatchlings of *Pseudablabes agassizii* at Minas Gerais, Brazil. EL = Egg length; EW = Egg width; SVL = Snout–vent length; TL = Tail length; BM = Body mass. Complementary measurements for hatchlings were taken in laboratory: HL = Head length; HH = Head height; HW = Head width.

Egg number	EL (mm)	EW (mm)	Hatching date	SVL (mm)	TL (mm)	HL (mm)	HH (mm)	HW (mm)	BM (g)	UFMG collection
1	18.0	11.0	16/12/2003	99.2	27.7	7.8	3.35	3.75	1.0	1550
2	19.0	12.0	16/12/2003	101.3	28.8	8.4	3.4	3.95	1.0	1549
3	19.2	10.7	16/12/2003	102	35.3	—	—	—	1.0	—
4	18.6	11.0	16/12/2003	100.2	28.6	7.6	3.0	3.7	1.0	1548

8	19.0	12.0	16/12/2003	100.4	30.3	—	—	—	1.01	—
Female				316	103.2	14.9	6.5	6.55	144	1547

Mean hatchling SVL was 102.84 mm ± 3.39 SD; TL 30.37 mm ± 2.35 SD; Mass 1.005 g ± 0.005 SD (Table 1). Five hatchlings were released in the field on 17 December 2003, and the others, as well as the female, were deposited in the herpetological collection of Universidade Federal de Minas Gerais (UFMG 1547–1550). The period of egg incubation of *P. agassizii* in captivity was 57–59 days. The female was collected in October, which corresponds to the beginning of the local rainy season (Galvão and Nimer 1965. *In* IBGE [ed.], Geografia do Brasil-Grande Região Leste, Vol. 5, pp. 91–139. Rio de Janeiro, Brazil). Our results are consistent with Marques et al. (*op. cit.*), in that egg-laying occurs mainly during the rainy season, and that *P. agassizii* produces small clutches compared to related species, likely owing to its small adult size.

We thank CEMIG and YKS Serviços Ltda for financial support, Maria Beatriz Ferreira and Vinícius Xavier for help with the fieldwork, Ricardo J. Sawaya and Paulo Passos for suggestions and comments on the manuscript, and Robert D. Aldridge for English revision.

Submitted by **RONALD REZENDE DE CARVALHO JÚNIOR,** Pontifícia Universidade Católica de Minas Gerais, Av. Dom José Gaspar 290, Coração Eucarístico, 30536-610, Belo Horizonte, MG, Brazil (e-mail: rcjunior.bh@terra.com.br); **MARCO ANTÔNIO SCHETTINO CANELAS** (e-mail: cotonhocanelas@yahoo.com) and **MARCELO DE CAMPOS CORDEIRO MALTA** (e-mail: mmalta@pbh.gov.br).

THAMNOPHIS HAMMONDII (Two-striped Gartersnake). **DIET.** *Thamnophis hammondii* ranges from central California, USA, to southern Baja California Sur, México (Grismer 2002. Amphibians and Reptiles of Baja California. Univ. California Press, Berkeley. 399 pp.; Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Books, Washington, D.C. 668 pp.); little is known about the feeding ecology of this largely aquatic snake in the southern edge of its distribution.

At 2334 h on 17 August 2005, we captured a female *T. hammondii* (CIBNOR 0659: 522 mm SVL, 138 mm TL; 77.8 g [without prey item]) on Arroyo Las Ánimas, San Pedro de la Presa Oasis, Municipio de La Paz, Baja California Sur, México (24°51'00.8"N, 110°59'30.4"W) that had eaten an adult female *Bufo punctatus* (Red-spotted Toad; CIBNOR 0660: 62 mm SVL; 18.6 g) rump first. The prey was in excellent condition; only the skin in the cloacal region was partially torn. A second female *T. hammondii* (CIBNOR 0657: 341 mm SVL, 87 mm TL; 18.6 g [without prey item]) from the same locality regurgitated a partially digested *Tilapia* cf. *T. zilli* (Redbelly Tilapia, Cichlidae). The fish was swallowed headfirst and the anterior half of the specimen had been digested; the fish remains weighed 0.42 g. On the same night, we saw a third *T. hammondii* traveling along rocks on the same section of the arroyo. The snake was following a similar route to that used by a *Peromyscus* sp. (Deer Mice) a moment earlier, perhaps an indication that the *T. hammondii* may have been trailing the rodent.

Our observations support the assertions that *T. hammondii* forages in and near the water, its prey include anurans and fishes, and although primarily a diurnal species, can be active at night during the summer (Grismer 2002, *op. cit.*; Ernst and Ernst 2003, *op. cit.*). The snakes and their prey were deposited in the herpetological collection of the Centro de Investigaciones Biológicas del Noroeste (CIBNOR), La Paz, Baja California Sur, México.

We thank José Abelino Cota, Yahirí Rodríguez, Armando Tejas, and Carmen D. Ortiz for field assistance, Lucía Campos for help identifying the fish remains, and Harry W. Greene for comments on the manuscript.

Submitted by **JAVIER A. RODRÍGUEZ-ROBLES**, Department of Biological Sciences, University of Nevada, Las Vegas, 4505 Maryland Parkway, Las Vegas, Nevada 89154-4004, USA (e-mail: javier.rodriguez@unlv.edu); and **PATRICIA GALINA-TESSARO,** Centro de Investigaciones Biológicas del Noroeste, S.C., División de Biología Terrestre, Baja California Sur, México (e-mail: pgalina04@cibnor.mx).

THAMNOPHIS VALIDUS CELAENO (Cape Gartersnake, Mexican Pacific Lowlands Gartersnake). **DIET.** *Thamnophis validus celaeno* is the only subspecies of the Mexican Pacific Lowlands Garter Snake that occurs in Baja California, where apparently is confined to water systems in the Cape Region of the peninsula (Rossman et al. 1996. The Garter Snakes: Evolution and Ecology. Univ. Oklahoma Press, Norman. 332 pp.; Grismer 2002. Amphibians and Reptiles of Baja California. Univ. California Press, Berkeley. 399 pp.).

On the afternoon of 22 August 2005, we caught a female *T. v. celaeno* (CIBNOR 0697: 348 mm SVL, 105 mm TL; 21.9 g [without prey item]) in a concrete irrigation canal on Cañada de San Bernardo, Rancho Boca de la Sierra, Reserva de la Biosfera Sierra de la Laguna, Municipio de Los Cabos, Baja California Sur, México (23°23'05.3"N, 109°49'06.1"W). The snake had eaten a *Bufo punctatus* (Red-spotted Toad; CIBNOR 0698) rump first. The posterior part of the toad, including the hind limbs, had been digested. The prey remains measured 51 mm in length and weighed 6.1 g. A second snake from the same locality had eaten another adult *B. punctatus* rump first. These records confirm that *B. punctatus* is an important trophic resource for *T. v. celaeno* (Conant 1969. Bull. Amer. Mus. Nat. Hist. 142:1–140; de Queiroz et al. 2001. Copeia 2001:1034–1042). The snakes and their prey were deposited in the herpetological collection of the Centro de Investigaciones Biológicas del Noroeste (CIBNOR), La Paz, Baja California Sur, México.

We thank José Abelino Cota and Israel Guerrero for field assistance, and Harry W. Greene for comments on the manuscript.

TROPIDOPHIS MACULATUS (NCN). **SIZE RECORD.** On 31 January 1981, Mercedes Reyes collected a male *Tropidophis maculatus* from 5th Ave., between 112 and 114, Playa, Havana City Province, Cuba. This specimen (CZACC 4.11988; Colecciones Zoológicas del Instituto de Ecología y Sistemática, Cuba) mea-

sures 375 mm snout–vent length, 53 mm tail length, and has 25-25-19 scale rows, 197 ventrals, 36 subcaudals, eight spot rows at midbody, 41/42 body and 9/9 caudal spots at dorsal midline, and external pelvic spurs. A female specimen (CZACC 4.11995) collected from Marianao, Havana City Province measures 372 mm SVL, 52 mm tail length, and has 25-25-21 scale rows, 196 ventrals, 34 subcaudals, 10 spot rows at midbody, 58/61 body and 9/9 caudal spots at dorsal midline. The previously reported maximum SVL for this species is 327 mm (males) and 347 mm (females) (Hedges 2002. Bull. Nat. Hist. Mus. Lond. [Zool.] 68[2]:83–91). These new specimens also expand the known range of body spot counts at dorsal midline from 35–55 to 35-61 (Hedges, *op. cit.*).

Submitted by **MICHEL DOMÍNGUEZ** (e-mail: michel.dominguez@ecologia.cu, micdom2002@yahoo.es) and **LUIS V. MORENO**, División de Colecciones Zoológicas, Instituto de Ecología y Sistemática, Carretera de Varona km 3 1/2, Capdevila, Boyeros, A.P. 8029, C.P. 10800, Ciudad de La Habana, Cuba.

TROPIDOPHIS MORENOI (NCN). **SIZE RECORD.** Previously reported measurements for the two known specimens *T. morenoi* (Hedges et al. 2001. J. Herpetol. 35:615–617) are 295 mm snout–vent length (SVL) and 45 mm tail length (TL) (holotype CZACC 4.5492; Colecciones Zoológicas del Instituto de Ecología y Sistemática, La Habana, Ciudad de La Habana province, Cuba; ex-collection IB 2493 from ex-Instituto de Biología, Cuba) and 285 mm SVL and 44 mm TL (Paratype CZACC 4.5493; ex-collection IB 2942). The type locality of this species is Dolinas de Cueva de Humboldt, Caguanes, Villa Clara Province, Cuba (22°50'04"N, 80°12'02"W). This place belongs now to the Sancti Spíritus Province. An adult female *Tropidophis* (CZACC 4.12052) was collected by J. Salas (unknown date) from the same locality. It was identified by MD as *T. morenoi* on 20 January 2004, and is the first specimen of *T. morenoi* reported after the species description (Hedges et al., *op. cit.*). Measurements of this specimen are: 359 mm SVL and 57 mm TL, which exceeds the previous records by 64 mm SVL and 12 mm TL. Measurements of the head were not possible to determine because the head and neck are damaged. Other characters of color, scale counts, and measures conform to those of the type series.

Submitted by **MICHEL DOMÍNGUEZ** (e-mail: michel.dominguez@ecologia.cu, micdom2002@yahoo.es), **LUIS V. MORENO**, and **LOURDES RODRÍGUEZ SCHETTINO** (e-mail: zoologia.ies@ama.cu.), Instituto de Ecología y Sistemática, Carretera de Varona km 3 1/2, Capdevila, Boyeros, A.P. 8029, C.P. 10800, Ciudad de La Habana, Cuba.

TROPIDOPHIS PARDALIS (NCN). **SIZE RECORD.** In July 1968, LVM collected a male *Tropidophis pardalis* from "La Catalina," Güines, Havana Province, Cuba. This specimen (CZACC 4.12042; Colecciones Zoológicas del Instituto de Ecología y Sistemática, Cuba) measures 284 mm snout–vent length, 38 mm tail length, and has 23-25-18 dorsal scale rows, 156 ventrals and 28 subcaudals, six spot rows at midbody, and 42/44 body spots at dorsal midline. A second male, collected by Julio Novo (date unknown) from Atabey, Playa, Havana City Province, Cuba (CZACC 4.8554), has 139 ventrals. A third male, collected by L. R. Hernández from Loma de la Esperanza, Sierra Morena, Villa Clara Province, Cuba on 26 May 1975 (CZACC 4.12012), has 160 ventrals. The previously reported maximum SVL for males of this species is 264 mm (Hedges 2002. Bull. Nat. Hist. Mus. Lond. [Zool.] 68[2]:83–91). The additional specimens expand the range of variation in ventral scale counts from 140–157 to 139–160 (Hedges, *op. cit.*).

Submitted by **MICHEL DOMÍNGUEZ** (e-mail: michel.dominguez@ecologia.cu, micdom2002@yahoo.es) and **LUIS V. MORENO**, División de Colecciones Zoológicas, Instituto de Ecología y Sistemática, Carretera de Varona km 3 1/2, Capdevila, Boyeros, A.P. 8029, C.P. 10800, Ciudad de La Habana, Cuba.

GEOGRAPHIC DISTRIBUTION

Instructions for contributors to Geographic Distribution appear in Volume 37, Number 1 (March 2006). Please note that the responsibility for checking literature for previously documented range extensions lies with authors. Do not submit range extension reports unless a thorough literature review has been completed.

CAUDATA

AMBYSTOMA OPACUM (Marbled Salamander). USA: TENNESSEE: Hawkins Co.: Holston Army Ammunition Plant located in the Kingsport Quad (36°32'05"N., 82°36'51"W). 13 April 1996. Harvey Hammock and John E. Copeland. Austin Peay State University Museum of Zoology, APSU 18168. Verified by A. Floyd Scott. Adult specimen found beneath roots of fallen tree. New county record that extends the range of the species in Tennessee into the eastern portion of Hawkins Co. (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp.).

and

HEIDI L. ROSS
Entrega General, Estafeta de Correos de Patilla
Panamá, Republic of Panama

The Panamanian Golden Frog, *Atelopus zeteki* Dunn (Anura: Bufonidae), is a taxon of concern endemic to the Coclé and Panamá Provinces of Panama (Dunn 1933; Savage 1972), principally inhabiting lowland rainforest (Savage 1972) on the Pacific cordilleran slope. Bufonidae are among four families of amphibians containing more "rapidly declining" species than the average (Stuart et al. 2004), and of 34 species of amphibians which have gone extinct since 1500 (Stuart et al. 2004), three were in the genus *Atelopus* (IUCN et al. 2004). In addition, of 77 described species of *Atelopus* (Frost 2004), 61 (82%) are listed as Critically Endangered (IUCN et al. 2004), and it has been suggested that this is the first example of a species-rich lineage being so uniformly imperiled (Lötters et al. 2004). In particular, *Atelopus zeteki* is listed as Critically Endangered (IUCN et al. 2004) and given the highest level of protection by the Convention on International Trade in Endangered Species (CITES I). Development of conservation strategies and long-term monitoring programs for threatened species is contingent upon understanding species' life histories. As basic biological and ecological information is lacking for many *Atelopus* species, collection of such data may be crucial for conservation efforts.

Relatively little is known about the reproductive ecology of *Atelopus* frogs (Lötters 1996). While breeding phenology usually varies somewhat among species and populations depending upon local climatic conditions, limited data suggest that *Atelopus* breeding generally occurs at the beginning of the dry season (Lötters 1996, Savage 2002). *Atelopus* oviposit in cryptic locations, attaching their eggs to the undersides of rocks in swiftly flowing streams generally during periods of low water flow (Savage 1972, Lötters 1996). Previous descriptions of egg-laying and clutch characteristics come principally from captive or dissected animals. The few reported field observations of egg masses or oviposition sites provide limited data on clutch sizes, ovum diameter, and/or oviposition site characteristics in *A. flavescens* (Lescure 1981) and *A. franciscus* (Boistel et al. 2005) from French Guyana, and *A. muisca* (Rueda-Almonacid and Hoyos 1991) from Colombia. To our knowledge, no published information from the field or laboratory exists on the reproductive ecology of *A. zeteki*. Our objectives were to describe the clutches and oviposition sites of *A. zeteki* and compare their reproductive ecology with that of other *Atelopus* species.

Materials and Methods.—In 10–16 December 2004 and 8–15 December 2005, we conducted surveys for *Atelopus zeteki* in Panamá Province, Panama, in a small stream ca. 5–15 m in width with steep rocky slopes. We searched for *A. zeteki* egg masses by overturning rocky substrates and submerged woody debris and examining accumulations of leaf litter within the stream channel along a 200 m reach. These searches were conducted in conjunction with surveys for adult *A. zeteki* along the stream margins and on exposed rocks and small islands within the stream. All frogs were marked by toe-clipping. When clutches were found, we counted the number of eggs per clutch and measured the diameters of at least 20 eggs, randomly chosen, from each of three clutches. Embryo developmental stages were estimated (Gosner 1960). To characterize the microhabitat at oviposition sites, we measured overstory canopy closure using a concave spherical densiometer (only in 2005), size of substrate (Platts et al. 1983) to which an egg mass was attached, predominant size of surrounding substrate (visually estimated within a 1 m^2 area centered on the oviposition substrate), water depth at the location of the clutch (only in 2004), distance of oviposition substrate to wetted edge, wetted width of stream at each oviposition site, stream velocity (m/s) near each egg mass, and instream habitat type (e.g., pool or riffle, Platts et al. 1983). Stream velocity at oviposition sites was estimated by determining the time it took for a floating object to travel a 1 m stream segment centered on the location of an egg mass. Velocity was calculated as the distance traveled divided by the time elapsed. In addition, we measured the distance between clutches within each year. In 2004, we measured general habitat conditions for five of the variables along the stream reach and

compared these with microhabitat characteristics at oviposition sites using Student's t-tests. Canopy closure was measured at the beginning and every 10 m along the reach within one m of the stream margin and averaged. We visually estimated the proportion of the surface of the streambed made up of cobble, gravel, pebble, sand, and silt (after Platts et al. 1983) within 20 randomly located 1-m wide bands that bisected the reach. Water depth was measured at three equidistant points across the width of the stream at 20 randomly selected locations along the 200 m reach. Depth measurements were averaged. We determined mean wetted width from measurements at 20 randomly selected locations along the reach. Stream velocity was measured within one meter of the margin at 20 randomly selected locations along the reach and averaged.

Results.—Over two breeding seasons, we found 17 clutches of eggs of *A. zeteki* within the 200 m-long reach and one clutch upstream of the reach. In 2004, we found 41 amplectant pairs, 208 single frogs, and seven clutches of eggs of *A. zeteki* during five surveys over a seven-day period. In 2005, we found four pairs, 166 individuals, and 11 clutches in five surveys over eight days. Each intact clutch appeared to contain a single strand of small, cream-colored eggs attached to a rocky substrate in the stream (Table 1). Strands were attached to the substrate and then wrapped back up on themselves creating two or more layers of eggs in a loose, elongated mass (Fig. 1). In 2004, most of the clutches found

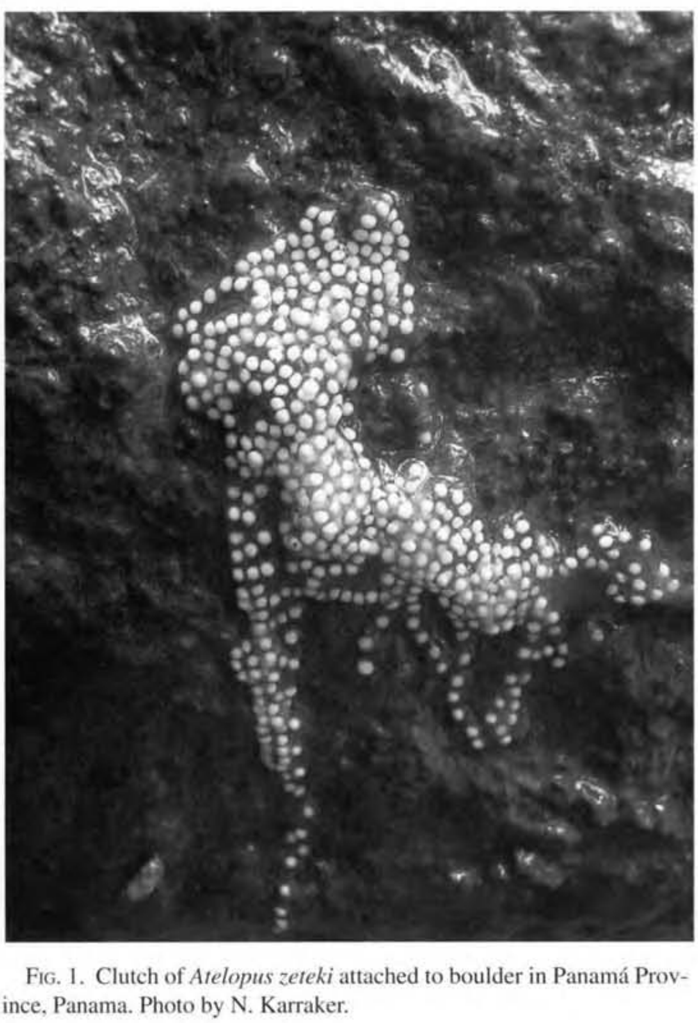

FIG. 1. Clutch of *Atelopus zeteki* attached to boulder in Panamá Province, Panama. Photo by N. Karraker.

appeared to have been recently oviposited, but in 2005 many of the clutches had begun hatching or had already hatched. Accurate counts of clutch size were made for five clutches in 2004 and four in 2005. Mean clutch size was 370 ± 137 (SD) (N = 9; Table 1). Eggs ranged in developmental stage from cleavage to hatching. We were unable to determine the duration of embryonic development in the field. But in captivity, the embryonic period of *A. zeteki* ranged 7–11 days at 22.0°C and averaged 8.9 ± 1.3 days (N = 9) (Detroit Zoo, unpubl. data).

Embryos averaged 1.8 ± 0.2 mm in diameter (range 1.4–2.5 mm, N = 60). Mean water temperature at oviposition sites was 23.4 ± 0.8°C (N = 15). On 11 December 2004, pH of the stream was 7.8. Six clutches were attached on the top, one on the side, and 11 on the undersides of substrates. All but one clutch were attached to cobble- or boulder-sized substrates (Table 1). All clutches but one were found within 2 m of the stream margin and were evenly distributed between riffle and run habitats. Percent canopy closure was lower (t = 2.04, $P = 0.050$) above oviposition sites at 93.1 ± 5.8 (range 85–100; N = 9), while the average for the reach was 96.9 ± 1.9 (range 91–99; N = 21). Sand was the predominant substrate type around oviposition sites for 15 of 18 (83%) clutches, while the proportions of surface substrates overall within the reach were 36% cobble, 31% sand, 20% pebble, 6% gravel, and 7% silt (N = 20). Water depth at oviposition sites averaged 16.5 ± 15.7 cm (range 1–44; N = 6), and was lower (t = 2.44, $P = 0.022$) than the average depth for the reach of 30.8 ± 11.0 cm (range 17–63; N = 20). Mean wetted width of the stream at oviposition sites was 9.9 ± 3.7 m (range 6.1–18.7; N = 15), and was higher (t = 2.94, $P = 0.006$) than the reach average of 7.7 ± 2.1 m (range 4.2–11.8; N = 20). Mean stream velocity at oviposition sites was 0.34 ± 0.15 m/s (range 0.10–0.50; N =15), and comparable (t = 0.74, $P = 0.463$) to the average for the reach of 0.37 ± 0.10 m/s (range 0.23–0.50; N = 20). Two clutches were separated from others by 22 m each, but the mean nearest neighbor distance between all other clutches within the reach was 1.1 ± 1.3 m (N = 15). Two clutches were found attached to the underside of the same boulder, 11 and 12 cm apart, in 2004 and 2005, respectively. In 2005, we found two clutches attached 12 cm apart on the underside of another boulder. Aside from the single clutch found upstream of the reach, all clutches in both years were located within a 25-m reach of stream.

Seven clutches were no longer submerged under water when found and one appeared to be covered by a white fungus. It had rained heavily in the area just prior to surveys each year, so presumably these exposed clutches were oviposited when the water level was higher in the stream.

Discussion.—We observed eggs of *Atelopus zeteki* in December 2004 and 2005, which marks the transition between rainy and dry seasons in most years. We observed amplectant pairs as early as 8 December in 2005 and as late as 25 January in 2004. Surveys of this site, associated with a separate study on population dynamics, in February, March, July, and August yielded no amplectant pairs. Small, but well-developed, larvae were observed in the stream in mid-December 2005, but no metamorphs or subadults were found, indicating that the breeding season probably begins in late November or early December and continues into January. Further evidence comes from observations made on 4 December 2003, in which no adults were observed along the stream, but males

TABLE 1. Clutch sizes, developmental stages (after Gosner 1960), and characteristics of oviposition sites of *Atelopus zeteki* observed in Panamá Province, Panama. Substrate size categories: silt (<0.06 mm), sand (0.06 to 2 mm), gravel (2 to 64 mm), cobble (64 to 256 mm), boulder (256 to 4096 mm), and bedrock (>4096 mm), as measured across the longest diameter (Platts et al. 1983). Habitat types follow Platts et al. (1983). — Indicates data were not collected. [1]Indicates clutches for which accurate counts could not be made. [2]Indicates clutches in which all other eggs appeared to have hatched.

Clutch size	Stage of development	Canopy closure	Water temp. (°C)	Substrate type	Surrounding substrate type	Distance from stream margin (cm)	Water depth (cm)	Habitat type	Stream flow (m/s)	Wetted width (m)

were heard calling at the forest edge, approximately 50 m upslope of the stream, and in damp wooded ditches that extended up into the adjacent clearing. No females were observed on that date, but on 12 December, 10 amplectant pairs were found by the stream (K. Zippel, pers. comm.). Hundreds of metamorphs were observed along the stream on 27 April 2002 (K. Zippel, pers. comm.). Oviposition in *A. chiriquensis*, another Panamanian species, probably occurs during the dry season as amplectant pairs were collected in February (Lindquist and Swihart 1997). Egg masses of *A. franciscus* from French Guyana were found in late April or early May (Boistel et al. 2005). In the same country, a clutch of *A. flavescens* eggs was found in July (Lescure 1981). In late October, a clutch of *A. muisca* was reported in Colombia (Rueda-Almonacid and Hoyos 1991). In *A. varius* in Costa Rica, breeding is estimated to begin in October and continue into early December (Crump 1988). These examples demonstrate the tremendous variation in timing of oviposition within this genus, which may be related to climatic differences between regions.

To our knowledge no clutches of *A. zeteki* have been previously reported, but descriptions of eggs and oviposition sites exist for other *Atelopus* species (Table 2). There appears to be much intraspecific variation in *Atelopus* clutch sizes. Fourteen clutches of *A. chiriquiensis* ranged from 170–603 eggs. We found that five clutches of *A. zeteki* ranged in size from 202–623 eggs. There is also interspecific variation in *Atelopus* ranging from 69 eggs in one clutch of *A. muisca* (Rueda-Almonacid and Hoyos 1991) to one of *A. varius* containing 910 eggs (McDiarmid 1971). In addition, ovum diameter varies widely in the genus, with 0.8 mm for *A. gracilis* (McDiarmid 1971) to 2.2 mm for *A. subornatus* (Lynch 1986). Ovum diameter in *A. zeteki* averaged 1.8 mm.

Duration of embryonic development has not been previously reported for *A. zeteki*. The duration of 7–11 days at 22°C reported here is comparable to the short periods described for other species of *Atelopus*. In the laboratory, eggs of *A. cruciger* hatched in three to four days at 20°C (Mebs 1980). Embryos of *A. varius* took six days to hatch in captivity (Starrett 1967), although no water temperature data were given. It appears from these limited data that the embryonic period in *Atelopus* may be relatively short.

Within our sampled reach, *A. zeteki* oviposited in wider stream sections, along shallow margins, and in fast water habitats with slightly lower canopy closure. In our study area, all clutches were attached to rocky substrates and 83% were attached to larger substrates, boulders, and bedrock. As eggs are laid during the transition between wet and dry seasons, selection of larger substrates for oviposition may reduce the risk of eggs being washed downstream in late rainy season storms, particularly in relatively confined channels such as the one in which the clutches were located. Eggs in four clutches were hatching when found. In each instance, as the rock was turned over, larvae were unable to adhere to the rock, indicating that the ventral sucking disc (Starrett 1967) characteristic of *Atelopus* either had not yet developed or does not function at hatching. Larvae slid from the remnants of the egg mass into the substrate below. It is notable that the larvae were similar in color to sand in the study area, which was the predominant substrate surrounding all but three of the clutches.

Females may select oviposition sites due to several factors including microhabitat characteristics, relative predation risk, and proximity to calling males. Although we searched 200 m of stream, 16 of 18 clutches were found within an average of 1.1 m of another clutch. Three pairs of these clutches, each pair at different development stages, were attached within 12 cm of each other on the underside of a boulder. This distribution of egg masses suggests that important locations for oviposition may be present along the stream and that communal oviposition occurs in *A. zeteki*. Communal oviposition has not been previously reported for any *Atelopus*. Communal oviposition occurs when the benefits of communal reproduction outweigh the losses to individual reproduction, females have limited clutch sizes, and suitable oviposition sites are uncommon (Robertson et al. 1998). Communal oviposition sites of *A. zeteki* may increase an individual's fitness by reducing the predation risk for a single clutch of eggs and distributing the risk among multiple clutches. The number of suitable locations for egg-laying in the vicinity of the oviposition sites reported here for *A. zeteki* is not known. However, the locations used may represent sites that are relatively stable from high flow events, during the breeding period, within those streams.

Acknowledgments.—We thank E. Griffith and K. Zippel for field assistance, and K. Zippel, N. Scott, and S. Lötters for helpful comments on previous drafts of this manuscript. We appreciate the logistical support of the Smithsonian Tropical Research Institute. Funding was provided by the Society for the Study of Amphibians and Reptiles (Grants-in-Herpetology award to CLR) and the National Science Foundation (Graduate Research Fellowship to CLR). This work was completed with applicable federal and international permits and in compliance with guidelines of the Institutional Animal Care and Use Committee (IACUC #8831, University of Michigan).

We summarize information on acoustics recorded from the anuran amphibians of Borneo. Currently, 154 species of frogs and toads (Amphibia: Anura) are known from Borneo (Das 2005; Das and Haas 2005; Inger and Stuebing 2005). The five species of Ichthyophiidae known from Borneo presumably do not call. The quality of acoustic information of Bornean amphibians reported in the literature varies significantly. In this review, we scored call data from 0–5, where 0 = unknown; 1 = abbreviated, onomatopoeic or verbal description; 2 = analytical description only, no sonogram/oscillogram; 3 = sonogram/oscillogram only, no analytical description; 4 = sonogram/oscillogram and analytical description; and 5 = recording on a CD. In the context of this review, "analytical description" refers to an explicit summary of important call characters, such as fundamental frequency, dominant frequency, and call rate. The respective references cited are in chronological order. We report whether descriptions are based on extralimital samples; all other references pertain to Borneo, and where possible, the locality of recording is mentioned.

In total, the calls of 101 species of anuran amphibians (65.6%) known from Borneo are described in the literature. The list includes calls of several species that have been described exclusively from extralimital areas (including India, Nepal, Thailand, and the Malay Peninsula). At least in some cases (e.g., *Fejervarya limnocharis* and *F. cancrivora*), the extralimital calls refer to nonconspecific cryptic species. In a manuscript under preparation, we will describe the calls of three additional species: *Bufo quadriporcatus*, *Leptolalax maurus* and *Microhyla borneensis* (Sukumaran et al., in prep.).

Species with unknown calls include the sole Bornean representative of Bombinatoridae (*Barbourula kalimantanensis*, an endemic of Kalimantan, Indonesia); 15 species of Bufonidae; four species of Megophryidae; 12 species of Microhylidae; 12 species of Ranidae; and nine species of Rhacophoridae. A number of familiar species from the family Ranidae have unknown calls, or have calls inadequately described in the literature. This may be due to the logistical difficulty in getting reliable recordings due to either calling behavior (such as short, sporadic calls; call shyness; or long periods between calls) or environment (e.g., high ambient noise levels in the stream habitat characteristic of many such ranids). In addition, males of some members of the genus *Limnonectes* lack vocal sacs, resulting in their characterization in the past as 'voiceless frogs' (e.g., Emerson and Inger 1992; Emerson and Berrigan 1993; Emerson et al. 1993; Emerson and Voris 1992). However, further observations have since established that females of some of these 'voiceless frogs' do indeed vocalize (see, for instance, Emerson 1992; Inger and Stuebing 2005; Matsui 1995).

Even when call descriptions are available, these may be in an abbreviated form (descriptive or onomatopoeic), lacking sonograms or oscillograms, and thereby not available for analysis. When descriptive accounts of calls are excluded, only 75 species (48.7% of the fauna) of Bornean frog calls have been analyzed. In many cases, no vouchers are listed, sometimes making identification of the species concerned uncertain.

Acknowledgments.—Supported by a grant from Volkswagen–Stiftung, Germany (grant I/79 405). We thank the Institute of Biodiversity and Environmental Conservation, Universiti Malaysia Sarawak, and Biozentrum Grindel und Zoologisches Museum, Universität Hamburg, for supporting our research on the amphibians of Borneo. Two anonymous reviewers commented on the manuscript, improving clarity.

TABLE 1. Checklist of anuran amphibians of Borneo, annotated with status information on bioacoustics and their sources. Status of descriptions: 0 = unknown; 1 = abbreviated, onomatopoeic or verbal description; 2 = analytical description only, no sonogram/oscillogram; 3 = sonogram/oscillogram only, no analytical description; and 4 = sonogram/oscillogram and analytical description.

	Status of description
Bombinatoridae	
Barbourula kalimantanensis	0
Bufonidae	
Ansonia albomaculata	1 (Inger and Stuebing, 2005)
Ansonia anotis	0
Ansonia fuliginea	0
Ansonia guibei	0
Ansonia hanitschi	1 (Inger and Stuebing, 2005); 4 (Malkmus et al., 2002: from Sungei Liwago, Gunung Kinabalu National Park, Sabah)
Ansonia latidisca	0
Ansonia leptopus	1 (Inger and Stuebing, 2005); 4 (Inger and Dring, 1988: from Kalabakan, Nanga Tekalit and Gunung Mulu National Park, both in Sarawak)
Ansonia longidigita	1 (Inger and Stuebing, 2005); 4 (Inger and Dring, 1988: from Gunung Mulu National Park, Sarawak; Malkmus et al., 2002: from Sungei Langanan, Gunung Kinabalu National Park, Sabah)
Ansonia minuta	0
Ansonia platysoma	1, 4 (Malkmus et al., 2002: from Sungei Wariu, Gunung Kinabalu National Park, Sabah)
Ansonia spinulifer	4 (Matsui, 1982b: from Sungei Muruk near Long Bawan, in East Kalimantan: as *Ansonia leptopus*; corrected to *Ansonia spinulifer* by the author via hand-written corrections in a reprint given to the authors)
Ansonia torrentis	4 (Dring, 1983b: from Gunung Mulu National Park, Sarawak)
Bufo asper	1 (Inger and Stuebing, 2005); 4 (Grosjean and Dubois, 2001: from Khao Chong, Thailand)
Bufo divergens	1 (Malkmus et al., 2002; Inger and Stuebing, 2005)
Bufo juxtasper	1 (Malkmus et al., 2002; Inger and Stuebing, 2005); 4 (Matsui, 1982a: from Ranau, Sabah)
Bufo melanostictus	1 (Daniel, 2002: India); 4 (Mou and Zhao, 1992: from China; Kanamadi et al., 1995b: from India; Roy et al., 1998: from India; Grosjean and Dubois, 2001: from India, Nepal, and Thailand); 5 (McKay and Case, 2005: from Bali, Indonesia)
Bufo quadriporcatus	4 (Sukumaran et al., in prep: from Sama Jaya Nature Reserve, Sarawak)
Leptophryne borbonica	0
Pedostibes everetti	0
Pedostibes hosii	1 (Dring, 1979: from Sungei Kelebang, Gunung Lawit, Peninsular Malaysia; Inger and Stuebing, 2005)
Pedostibes maculatus	0
Pedostibes rugosus	0
Pelophryne api	4 (Dring, 1983b: from Gunung Api and Bukit Pala, Gunung Mulu National Park, Sarawak)
Pelophryne brevipes	0
Pelophryne exigua	0
Pelophryne guentheri	0
Pelophryne macrotis	0
Pelophryne misera	1 (Inger and Stuebing, 2005); 4 (Malkmus et al., 2002: from Sungei Liwago, Kinabalu National Park, Sabah)
Pelophryne rhopophilus	0
Pelophryne signata	0
Pseudobufo subasper	1 (Kiew, 1972: from Tasek Bera, Peninsular Malaysia; Lim and Ng, 1992: from Peninsular Malaysia)
Megophryidae	
Leptobrachella baluensis	1, 4 (Dring, 1983a: from Gunung Mulu National Park, Sarawak)
Leptobrachella brevicrus	1, 4 (Dring, 1983a: from Gunung Mulu National Park, Sarawak)
Leptobrachella mjobergi	1, 4 (Dring, 1983a: from Gunung Mulu National Park, Sarawak; tentatively assigned to *Leptobrachella mjobergi*)
Leptobrachella parva	1, 4 (Dring, 1983a; Malkmus et al., 2002: from Gunung Mulu, Fourth Division, Sarawak)
Leptobrachella palmata	0
Leptobrachella serasanae	0
Leptobrachium abbotti	1 (Inger and Stuebing, 2005); 4 (Malkmus et al., 2002: from Sungei Kipungit, Gunung Kinabalu, Sabah)
Leptobrachium gunungense	4 (Malkmus et al., 1996b; 2002: from Sungei Carson, Gunung Kinabalu National Park, Sabah; comparisons with that of *Leptobrachium montanum*)
Leptobrachium hendricksoni	0
Leptobrachium montanum	1 (Inger and Stuebing, 2005); 4 (Malkmus, 1996; Malkmus et al., 2002: from Gunung Kinabalu National Park Headquarters, Sabah; compared with that of *Leptobrachium gunungense*)
Leptobrachium nigrops	1 (Kiew, 1972: from Tasek Bera, Peninsular Malaysia)
Leptolalax arayai	4 (Matsui, 1997: from Gunung Kinabalu National Park Headquarters, Sabah; Malkmus et al., 2002: from Silau-Silau, Gunung Kinabalu National Park, Sabah); also, as *Leptolalax gracilis* by Malkmus and Riede (1993)
Leptolalax dringi	4 (Matsui, 1997; Malkmus et al., 2002: from Gunung Mulu National Park, Sarawak)
Leptolalax gracilis	4 (Matsui, 1997: from Gunung Serapi, Matang, Sarawak; Camp Two, Gunung Mulu National Park, Sarawak; comparison made between audio data from these recordings by Malkmus and Riede, 1993). However, the identity of the individual from latter locality is tentative, as its call structure varies significantly from other documentations of *gracilis* calls
Leptolalax hamidi	4 (Matsui, 1997: from Bukit Lanjak, Sarawak)
Leptolalax maurus	4 (Sukumaran et al., in prep.: from Sungei Mesilau, Gunung Kinabalu National Park, Sabah)
Leptolalax pictus	4 (Malkmus and Riede, 1993: from Sungei Langanan, Gunung Kinabalu National Park, Sabah; compared with that of *Leptolalax gracilis;* Malkmus et al., 2002: from Sungei Kipungit, Gunung Kinabalu National Park, Sabah)
Megophrys baluensis	4 (Malkmus and Riede, 1996c: from Sungei Liwago, Gunung Kinabalu National Park, Sabah; Malkmus et al., 2002: from Sungei Lanaga, Gunung Kinabalu National Park, Sabah)

TABLE 1. Continued.

	Status of description
Megophrys edwardinae	0
Megophrus kobayashii	4 (Malkmus and Matsui, 1997; Malkmus et al., 2002: from Gunung Kinabalu National Park Headquarters, Sabah)
Megophrys nasuta	1 (Dring, 1979: from Sungei Kelebang, Gunung Lawit, Peninsular Malaysia; Inger and Stuebing, 2005); 1, 4 (Malkmus et al., 2002: from Poring, Gunung Kinabalu National Park, Sarawak)
Microhylidae	
Calluella brooksi	0
Calluella flava	0
Calluella smithi	0
Chaperina fusca	1 (Inger and Stuebing, 2005); 1, 4 (Malkmus et al., 2002: from Sayap, Gunung Kinabalu National Park, Sabah)
Gastrophrynoides borneensis	0
Kalophrynus baluensis	1 (Inger and Stuebing, 2005); 4 (Malkmus and Riede, 1996c; Malkmus et al., 2002: from Gunung Kinabalu National Park Headquarters; Sabah); 3 (Malkmus, 1994)
Kalophrynus eok	1 (Das and Haas, 2003: from Long Re, Sarawak)
Kalophrynus heterochirus	0
Kalophynus intermedius	0
Kalophrynus nubicola	4 (Dring, 1983b: from Gunung Mulu National Park, Sarawak; three distinct call types were identified, which may be attributable to genetic variation as well as environmental factors)
Kalophrynus pleurostigma	4 (Matsui, 1996: from Sepilok, Sabah, and Niah, Sarawak; with comparison with calls of *Kalophrynus interlineatus*); 4 (Malkmus et al., 2002: from Sepilok, Sabah)
Kalophrynus punctatus	0
Kalophrynus subterrestris	0
Kaloula baleata	1 (Inger and Stuebing, 2005); 4 (Malkmus et al., 2002: from Poring, Gunung Kinabalu National Park, Sabah); 5 (McKay and Case, 2005: from Bali, Indonesia)
Kaloula pulchra	1 (Inger and Stuebing, 2005); 3 (Heyer, 1971: from Thailand)
Metaphrynella sundana	1 (Inger and Stuebing, 2005); 3 (Matsui et al., 1996; Lardner and bin Lakim, 2002: from Poring, Sabah); 4 (Hoffmann, 2000; Malkmus et al., 2002; Lardner and bin Lakim, 2004: from Poring, Sabah). Also, discussion of possible acoustic convergence with *Tympanophyllum* sp. (Orthoptera: Tettigoniidae) in Malkmus (1995)
Microhyla berdmorei	0
Microhyla borneensis	4 (Sukumaran et al., in prep: from Kubah National Park, Sarawak)
Microhyla maculifera	0
Microhyla perparva	0
Microhyla petrigena	0
Ranidae	
Fejervarya cancrivora	4 (Matsui, 1982b: from Tarakan, East Kalimantan)
Fejervarya limnocharis	1 (Kiew, 1972: from Tasek Bera, Peninsular Malaysia; Inger and Stuebing, 2005); 2 (Dring, 1979: from Sungei Kelebang, Gunung Lawit, Peninsular Malaysia); 4 (Dubois, 1975: from Nepal; Mou and Zhao, 1992: from China; Kanamadi et al., 1995a: from India; Roy and Elepfandt, 1993; Roy, 1994; Roy et al., 1995; 1998: from northeast India; Malkmus et al., 2002: from Peninsular Malaysia); 5 (McKay and Case, 2005: from Bali, Indonesia)
Hoplobatrachus sinensis	1 (Inger and Stuebing, 2005)
Huia cavitympanum	1 (Inger and Stuebing, 2005)
Ingerana baluensis	1 (Malkmus et al., 2002)
Limnonectes asperata	0
Limnonectes finchi	1 (Malkmus et al., 2002; Inger and Stuebing, 2005)
Limnonectes ibanorum	0
Limnonectes ingeri	0
Limnonectes kenepaiensis	0
Limnonectes kuhlii	1 (Inger and Stuebing, 2005); 3 (Tsuji, 2004: from Taiwan, Republic of China); 4 (Malkmus et al., 2002)
Limnonectes laticeps	1, 2 (Dring, 1979: from Sungei Kelebang, Gunung Lawit, Peninsular Malaysia)
Limnonectes leporinus	1 (Emerson, 1992: from Sabah: as *Rana blythi*)
Limnonectes malesianus	0
Limnonectes palavanensis	1 (Inger and Stuebing, 2005); 4 (Malkmus et al., 2002: from Gunung Mulu National Park, Sarawak)
Limnnectes paramacrodon	0
Limnonectes rhacodus	0
Meristogenys amoropalamus	0
Meristogenys jerboa	4 (Matsui et al., 1993: from Gunung Serapi, Matang, Sarawak)
Meristogenys kinabaluensis	1 (Malkmus et al., 2002)
Meristogenys macrophthalmus	0
Meristogenys orphocnemis	4 (Malkmus et al., 2002: from Sungei Kepungit, Poring, Gunung Kinabalu National Park, Sabah)
Meristgenys phaeomerus	1 (Inger and Stuebing, 2005)
Meristogenys poecilus	0
Meristogenys whiteheadi	0
Occidozyga baluensis	1 (Inger and Stuebing, 2005); 4 (Malkmus et al., 2002: from Gunung Mulu National Park, Sarawak)
Occidozyga laevis	1 (Alcala, 1962: from Negros, Philippines); 3 (Malkmus et al., 2002); 4 (Alcala et al., 1986: from Luzon, Philippines); 5 (McKay and Case, 2005: from Bali, Indonesia)

TABLE 1. Continued.

	Status of description
Rana baramica	1 (Arak, 1984: from Ulu Gombak, Selangor, Peninsular Malaysia; Inger and Stuebing, 2005); 1, 2 (Dring, 1979: from Sungei Kelebang, Gunung Lawit, Peninsular Malaysia); 2 (Matsui, 1993); 4 (Leong et al., 2003: from Semantan and Niah, Sarawak, and Kuala Lumpur and Templer's Park, Peninsular Malaysia, with particular attention to distinguish from calls of *Rana laterimaculata*)
Rana erythraea	1 (Malkmus et al., 2002; Inger and Stuebing, 2005); 3 (Arak, 1984: from Ulu Gombak, Selangor, Peninsular Malaysia; 4 (Alcala et al., 1986: from Negros, Philippines). The record of Roy et al., 1995 (from northeast India) are here considered to be based on one or more non-conspecific individuals, as their Fig. 1A, purported to be this species, is actually *Polypedates maculatus*; while Fig. 2A is an indeterminate species of *Rana* (of the *Sylvirana* group).
Rana glandulosa	1 (Inger and Stuebing, 2005); 2 (Matsui, 1993); 4 (Sanchez-Herraiz et al., 1995: from Gunung Mulu National Park and Bako National Park, both in Sarawak)
Rana hosii	1 (Arak, 1984: from Ulu Gombak, Selangor, Peninsular Malaysia; 2 (Malkmus et al., 2002; Matsui, 1993); 4 (Matsui, 1982b: from Bawan River, East Kalimantan)
Rana laterimaculata	1 (Arak, 1984: from Ulu Gombak, Selangor, Peninsular Malaysia: as *Rana cryptica* nomen nudum); 4 (Leong et al., 2003: from Semantan and Niah, Sarawak, and Kuala Lumpur and Templer's Park, both in Peninsular Malaysia, with particular attention to distinguish from calls of *Rana baramica*)
Rana luctuosa	1 (Malkmus et al., 2002; Inger and Stuebing, 2005); 2 (Matsui, 1993)
Rana nicobariensis	1 (Kiew, 1972: from Tasek Bera, Peninsular Malaysia; Inger and Stuebing, 2005); 2 (Matsui, 1993); 3 (Arak, 1984: from Ulu Gombak, Selangor, Peninsular Malaysia; 4 (Matsui, 1982a: from Ranau, Sabah: as *Rana erythraea*, fide hand-corrected reprint received from M. Matsui; Malkmus et al., 2002: from Poring, Gunung Kinabalu National Park, Sabah); 5 (McKay and Case, 2005: from Bali, Indonesia). Also, 4 (Matsui, 1982b: from Long Bawan, East Kalimantan, compares the Ranau, Sabah, population, as *Rana erythraea*)
Rana picturata	Due to the confusion between *Rana picturata* Boulenger, 1920 and *Rana signata* (Günther, 1872) (and possibly others within the complex), it is difficult to treat call attributions as reported in literature with any degree of confidence. Malkmus et al. (2002) discuss the conflicting call descriptions that result from the confusion over the species complex and provide a sonogram of a call attributed to *Rana signata* and *Rana picturata*. Sonograms and analysis of calls of individuals identified as *Rana signata* from Gunung Mulu National Park and Bako National Park, Sarawak given in Sanchez-Herraiz et al. (1995). Inger and Stuebing (2005) provide a description of a call attributed to *Rana picturata*
Rana raniceps	1 (Inger and Stuebing, 2005; Malkmus et al., 2002: as *Rana chalconota*); 2 (Matsui, 1993: as *Rana chalconota*)
Rana signata	2 (Dring, 1979: from Gunung Lawit, Peninsular Malaysia; 2 (Matsui, 1993). See also comments under *Rana picturata*
Staurois guttatus	1 (Malkmus et al., 2002; Inger and Stuebing, 2005: as *Staurois natator*)
Staurois latopalmatus	1 (Davison, 1984: from Kuala Temawai, Brunei Darussalam; Malkmus et al. 2002; Inger and Stuebing, 2005); 4 (Hödel and Amézquita, 2001: from Danum Valley, Sabah)
Staurois parvus	0
Staurois tuberilinguis	1 (Inger and Stuebing, 2005); 4 (Malkmus et al., 2002: from Sungei Liwago, Gunung Kinabalu National Park, Sabah)
Rhacophoridae	
Nyctixalus pictus	1, 4 (Matsui, 1996: from the Park Headquarters, Gunung Mulu National Park, Sarawak; Malkmus et al., 2002: from Sungei Liwago, Gunung Kinabalu National Park, Sabah)
Philautus acutus	4 (Dring, 1987: from Gunung Mulu National Park, Sarawak)
Philautus amoeanus	4 (Malkmus and Riede, 1996a; Malkmus et al., 2002: from Pondok Ubah, Gunung Kinabalu National Park, Sabah)
Philautus aurantium	4 (Malkmus and Riede, 1996b, compared with *Philautus gunungensis*).
Philautus bunitus	1, 4 (Malkmus and Riede, 1996a; Malkmus et al., 2002: from Sungei Liwago, Gunung Kinabalu National Park, Sabah)
Philautus disgregus	0
Philautus erythropthalmus	0
Philautus gunungensis	4 (Malkmus and Riede, 1996b; Malkmus et al., 2002: from Silau-Silau, Gunung Kinabalu National Park, Sabah)
Philautus hosii	1 (Dring, 1987: from Gunung Mulu National Park, Sarawak; Inger and Stuebing, 2005)
Philautus ingeri	1 (Dring, 1987: from Gunung Mulu National Park, Sarawak; Malkmus et al., 2002; Inger and Stuebing, 2005)
Philautus kerangae	4 (Dring, 1987: from Gunung Mulu National Park, Sarawak)
Philautus longicrus	1 (Malkmus et al., 2002)
Philautus mjobergi	1, 4 (Malkmus et al., 2002: from Sungei Silau-Silau, Gunung Kinabalu National Park, Sabah; 4 (Dring, 1987: from Gunung Mulu National Park, Sarawak). Also, sonograms and comparison with call of *Philautus saueri* in Malkmus and Riede, 1996a)
Philautus petersi	1 (Inger and Stuebing, 2005); 4 (Dring, 1987: from Gunung Mulu National Park, Sarawak; Malkmus and Riede, 1996a; Hoffmann, 1998: from Sayap, Gunung Kinabalu National Park, Sabah; Malkmus et al., 2002: from Sungei Liwago, Gunung Kinabalu National Park, Sabah)
Philautus refugii	0
Philautus saueri	1, 4 (Malkmus and Riede, 1996a: Malkmus et al., 2002: from Pakka Cave, Gunung Kinabalu National Park, Sabah; comparative analysis with call of *Philautus mjobergi* in Malkmus and Riede, 1996a)
Philautus tectus	1 (Dring, 1987: from Gunung Mulu National Park, Sarawak)
Philautus umbra	1 (Dring, 1987: from Gunung Mulu National Park, Sarawak)
Polypedates chlorophthalmus	0
Polypedates colletti	1 (Inger and Stuebing, 2005)
Polypedates leucomystax	1 (Kiew, 1972: from Tasek Bera, Peninsular Malaysia; Inger and Stuebing, 2005); 4 (Matsui, 1982a: from Ranau, Sabah; Brzoska et al., 1986: from Negros, Philippines; Sanchez-Herraiz et al., 1995: from Gunung Mulu National Park and Bako National Park, both in Sarawak; Narins et al., 1998: from Ulu Gombak, Peninsular Malaysia; Roy et al., 1998: from India; Trépanier et al., 1999: from Vietnam); 5 (McKay and Case, 2005: from Bali, Indonesia)
Polypedates macrotis	1 (Inger and Stuebing, 2005); 4 (Matsui, 1982b; Malkmus et al., 2002: from Long Api, East Kalimantan)
Polypedates otilophus	1 (Inger and Stuebing, 2005; Malkmus et al., 2002)
Rhacophorus angulirostris	1 (Inger and Stuebing, 2005); 1, 2 (Malkmus et al., 2002)

TABLE 1. Continued.

	Status of description
Rhacophorus appendiculatus	1 (Inger and Stuebing, 2005); 2 (Dring, 1979: from Sungei Kelebang, Gunung Lawit, Peninsular Malaysia); 4 (Malkmus et al., 2002: from Danum Valley, Sabah; Hopkins et al., in prep.: from Sepilok, Sabah)
Rhacophorus baluensis	1 (Inger and Stuebing, 2005); 1, 4 (Malkmus et al., 2002: from Gunung Mulu National Park, Sarawak)
Rhacophorus cyanopunctatus	1, 2 (Dring, 1979: from Sungei Kelebang, Gunung Lawit, Peninsular Malaysia); 3 (Malkmus et al., 2002, provided analysis of Dring's 1979 data)
Rhacophorus dulitensis	1 (Malkmus et al., 2002; Inger and Stuebing, 2005)
Rhacophorus everetti	1 (Malkmus et al., 2002; Inger and Stuebing, 2005)
Rhacophorus fasciatus	0
Rhacophorus gadingensis	0

In reptiles, skin pigmentation can be important in crypsis, communication, and thermoregulation (Cooper and Greenberg 1992). Patterns of melanism of skin and shells of freshwater turtles can be described as permanent (heavy pigmentation of the shell throughout life), seasonal (changes in melanin distribution during sexual cycles), senile reticulate (melanization of some areas in some old individuals within the population), and ontogenetic (increases or decreases in skin melanin content with age, Lovich et al. 1990). Under laboratory conditions, melanin content of the skin of some side-neck turtles increases when turtles are maintained on dark-colored backgrounds when compared to those maintained on light-colored backgrounds (Banks 1986; Woolley 1957). Such phenotypic plasticity (Alpert and Simms 2002) in melanin content in dorsal skin may facilitate background color convergence in a turtle species that resides in different habitats with variable substrate colors (Lovich et al. 1990). Background color convergence may reduce predation rates (Cooper and Greenberg 1992) or make turtles more effective predators because they are less easily detected by prey (Green and Leberg 2005). To date, little information exists on how integument color varies among populations of freshwater turtles residing in environments with different substrate colors. Such studies might generate insights into the ecological

and evolutionary importance of pigmentation in freshwater turtles.

Painted Turtles (*Chrysemys picta*) are a North American emydid that occupy a range of freshwater habitats and therefore are ideal for assessing inter-population variation in shell color. The carapace of *Chrysemys picta* ranges from olive to black (Ernst et al. 1994), and sexual dimorphism in shell color is not apparent other than the reticulate melanism that may develop on the carapaces of some older male individuals (MacCulloch 1981; Smith et al. 1969). The plastron tends to lack dark pigment at the margins but may have more centrally-located dark pigment. We studied shell color within and among populations of wild-caught Midland Painted Turtles (*Chrysemys picta marginata*) of the Beaver Island Archipelago using photographic digital and spectrometric techniques in the laboratory. We compared the degree of shell darkness (intensity) among populations residing in black-substrate inland swamps, marshes, and lakes, as well as in the relatively light-colored sand and algae covered substrates of Lake Michigan bays. We focused on the carapace ground color because it is the largest dorsal region that would be viewed against the substrate by picine or avian predators (Stuart-Fox et al. 2004). Although background color convergence would presumably be most important to small, juvenile turtles that would be most vulnerable to predation, our data set included mainly sub-adult or adult turtles. Color change, however, has been shown to occur in adult individuals (Banks 1986; Woolley 1957) and therefore background color convergence might be manifested in all ages and sizes of turtles. If background color convergence occurs, then turtles from environments with dark-bottomed substrates would be expected to have darker carapaces than individuals from light-colored substrates of Lake Michigan harbors.

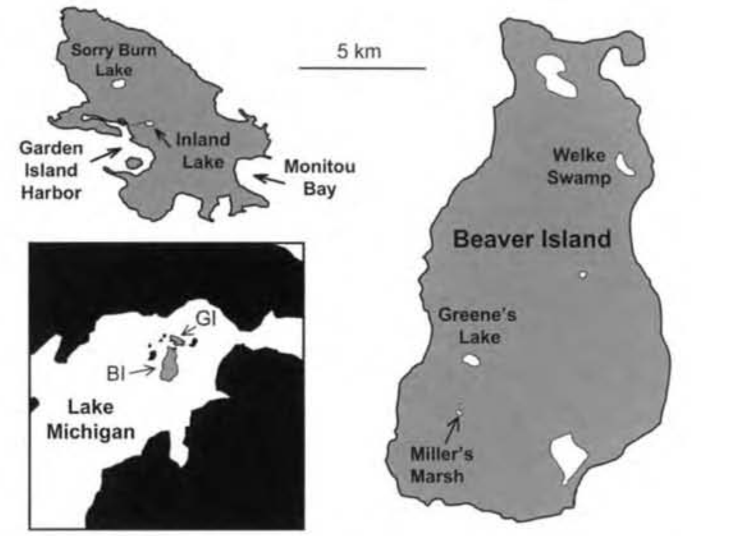

FIG. 1. Map of study sites on Garden Island (GI) and Beaver Island (BI) and the location of the Beaver Island Archipelago in northern Lake Michigan between the Upper and Lower Peninsulas of Michigan (inset).

MATERIALS AND METHODS

Study sites and collection of turtles.—We collected turtles during June and July in 2000–2003 by hand or using baited hoop nets, fyke nets, and basking traps. We selected study sites where the substrate of the bottom was relatively uniform throughout the habitat and avoided sampling from populations living in habitats with heterogeneous bottom substrates (e.g., with sandy, muck, and leaf-covered mosaics). We collected turtles from three inland sites on Beaver Island (45°36'N, 85°35'W, Fig. 1). Miller's Marsh and Greene's Lake are relatively small bodies of water with dark muck bottoms and clumps of water lilies (*Nuphar* sp. or *Nymphaea* sp.), cattails (*Typha latifolia*), and various *Potamogeton* species. Welke Swamp is an inland cedar swamp of northeastern Beaver Island that is mainly a black muck-bottomed habitat with some submerged aquatic vegetation. Inland sites on Garden Island (45°47'N, 85°30'W) included Sorry Burn Lake and Garden Island Inland Lake that were both dark muck-bottomed lakes and surrounded by floating vegetation mats. Lake Michigan harbor sites included Monitou Bay and Garden Island Harbor that were both relatively shallow bays (< 5 m maximum depth) associated with Lake Michigan. Although these Lake Michigan habitats were heterogeneous in that they had rock or soft bottoms, a thin layer of light brown to green-yellow algae covered each type of substrate giving the substrate a relatively uniform color. Large stands of aquatic vegetation were present, mainly wild celery (*Vallisneria americana*) and coontail (*Ceratophyllum demersum*).

Photographic digital images.—We obtained JPEG images (1600 × 1200 pixels) of turtles collected during 2000 (ca. 90%) and 2001 (ca. 10%). A Nikon Coolpics 800 digital camera was placed on a camera stand equipped with four 60-watt soft-light incandescent bulbs. Turtle shells were rinsed with tap water, dried completely and then placed horizontally in a restraining device such that the top of the carapace was relatively level and 20 cm below the camera lens. Lights were adjusted such that they shined from anterior and posterior locations with ray angles that were at about 30° to the perpendicular of the carapace or plastron. The camera was set to accommodate incandescent light at f 3.5 at 1/60 sec and macro settings were employed although no zoom was used. To provide a color standard, a 2 × 4 cm gray card was placed on the turtle's shell at a location that was off-center within the field of view. We used a personal computer equipped with Image-Pro Express 4.0 software to determine intensity values of carapaces and plastrons from the JPEG images, which was measured as pixel counts of 8-bit values that ranged between 0 (black) and 255 (white). Intensity, or brightness, is a dimensionless variable that measures the relative reflectance of an object where low values represent dark color and high values represent light color (Cooper and Greenberg 1992). The third vertebral scute of the carapace was used to represent the carapace as it was relatively flat which eliminated glare. Using the geometric shape function of the software program, we formed a rectangle that enclosed a majority of the area of the third vertebral scute and determined intensity for that area. While the ventrally-located plastron would not be expected to vary in color as a function of substrate color, we measured intensity of the left abdominal scute of the plastron for comparison with the carapace. We restricted our measurements to a rectangular area of the lateral region of the abdominal scute of the plastron because it lacked black pigment allowing us to evaluate variation in relative darkness between the plastron and carapace. We also took intensity readings from the gray cards in each image of the carapace and plastron. Most turtles that were less than 50 mm could not be used because the curvature of the carapace of these individuals caused

noticeable glare. Also, we collected only one individual that was less than 120 mm at the Lake Michigan habitats (Garden Island Harbor and Monitou Bay). Turtles whose shells were greatly flaking or that were opaque because they were in the advanced stages of scale sloughing were also excluded from the data set.

Spectrometric analysis of shell color.—To assess color quality in terms of reflected wavelengths and intensity, we used a spectrometric technique on turtles from three of the seven populations that were studied using the JPEG digital image technique (Garden Island Harbor, Miller's Marsh, and Welke Swamp which represented carapace intensity extremes and an intermediate shell color). Reflectance spectra of turtle carapaces were obtained in the laboratory under standardized conditions (June and July, 2002 and 2003) using a reflectance probe (Ocean Optics R-400) connected to a deuterium-halogen lamp (Ocean Optics) of an Ocean Optics USB 2000 portable spectrometer, and a notebook computer running Ocean Optics OOI Base 32 software. Subjects were placed at a fixed distance of 0.5 cm from the probe and reflectance of the shell surface was sampled at 30° from the perpendicular. A white standard (Labsphere Spectral WS-1) was scanned and dark current removed from the signal immediately before a reading was taken. Our data included wavelengths that spanned both the visible and ultraviolet spectra (330–700 nm). We included a portion of the UV spectrum as some potential fish predators may have visual systems that are UV-sensitive (Bowmaker 1991; Yokoyama and Yokoyama 1996). Intensity was measured as the total area under the spectral curve between 330–700 nm where the median % reflectance of each 20-nm increment was determined and summed per spectral reading (Macedonia et al. 2003).

Statistical analyses.—Carapace and plastron intensities as determined by JPEG and spectrometric techniques were approximately normally distributed and so were analyzed by ANOVA. *Post hoc* tests were conducted using least squares means multiple t-tests. Alpha values for all tests were 0.05.

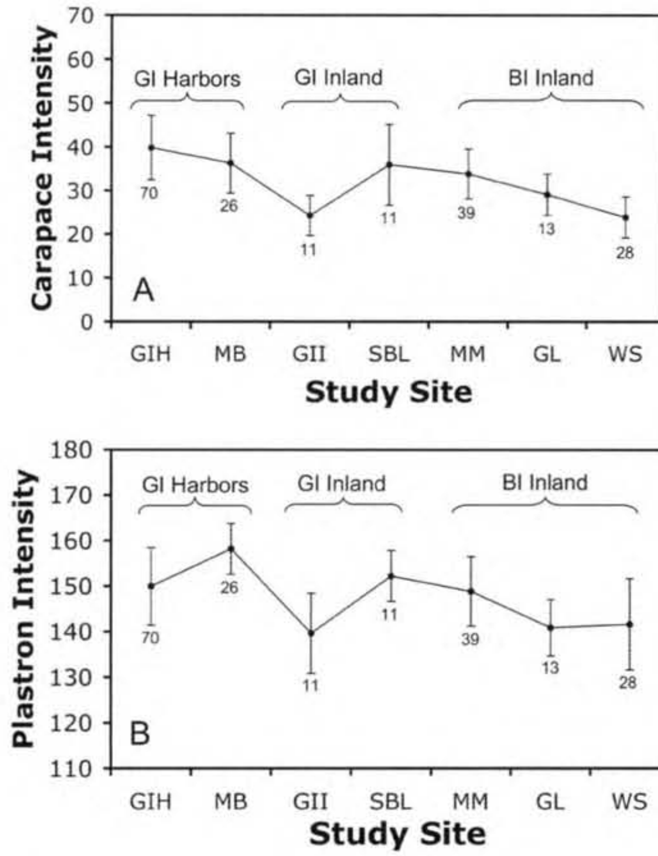

FIG. 2. Mean intensity values for (A) the third vertebral scute and (B) the lateral margin of the left abdominal scute of *Chrysemys picta* from seven different locations on Beaver and Garden Islands. Vertical lines are ± 1 SD and sample sizes are shown below.

RESULTS

Photographic digital images.—Intensities of the third vertebral scute and its associated gray card were not correlated ($P > 0.05$ in all correlations) indicating that variation in lighting conditions among JPEG images was minimal. Within a site, intensity of the third vertebral scute of the carapace (carapace intensity or CI) was not correlated with carapace length ($P > 0.05$ in all cases) nor did it vary between male and female turtles ($P > 0.05$ in all cases). Therefore, we combined juveniles, males, and females into single data sets that represented individuals from each study site. There were significant differences in CI among sites (model: $F_{6,191} = 26.7$, $P < 0.0001$, $R^2 = 0.46$, Fig. 2A and Fig. 3A–C). Least squares (LS) means multiple t-tests indicated that turtles from Garden Island Harbor (a light-substrate Lake Michigan harbor habitat) were lighter (i. e. had greater LS mean CI values) than turtles from other localities, and turtles from Welke Swamp and Garden Island Inland Lake (dark-substrate inland habitats) were darker than turtles from all other populations ($P < 0.05$ in all comparisons). Mean intensity of the third vertebral scute of turtles from Monitou Bay (a light-substrate Lake Michigan harbor habitat), Sorry Burn Lake, and Miller's Marsh (both inland habitats with dark substrates) were not significantly different from one another ($P > 0.05$ in each case) and each had greater LS mean intensity than turtles from the dark substrate, inland Greene's Lake ($P < 0.05$ in all comparisons). Therefore, although mean carapace intensity was highest (lightest in color) and lowest (darkest in color) in environments with light and dark substrates respectively, mean carapace intensity was intermediate in some populations that had either light or dark substrates.

Within populations, plastron intensity (PI) was not affected by gender or body size, and gender and body size data were combined within sites for analyses among sites. There was significant variation in PI among sites ($F_{6,191} = 13.9$, $R^2 = 0.31$)(Fig. 2B and Fig. 3D–F). Turtles from Monitou Bay had significantly greater LS mean PI than turtles from other populations ($P < 0.005$ in all cases). Plastrons of turtles from Sorry Burn Lake, Garden Island Harbor, and Miller's Marsh were similar in intensity ($P > 0.05$ in all comparisons) and each had greater LS mean PI than turtles from Welke Swamp, Greene's Lake, and Garden Island Inland Lake which were all statistically indistinguishable from one another.

We did not notice any obvious dark staining by exogenous factors (e.g., tannins) of the shell within any population, particularly on the plastron where it would be most evident because of its light color (Fig. 3D–F). Within sites, PI and CI were not correlated ($P > 0.05$ in all regressions) as would be expected if an exogenous factor affected intensity values of the shell. When PI is regressed on CI, a slope of approximately one would be expected if exogenous

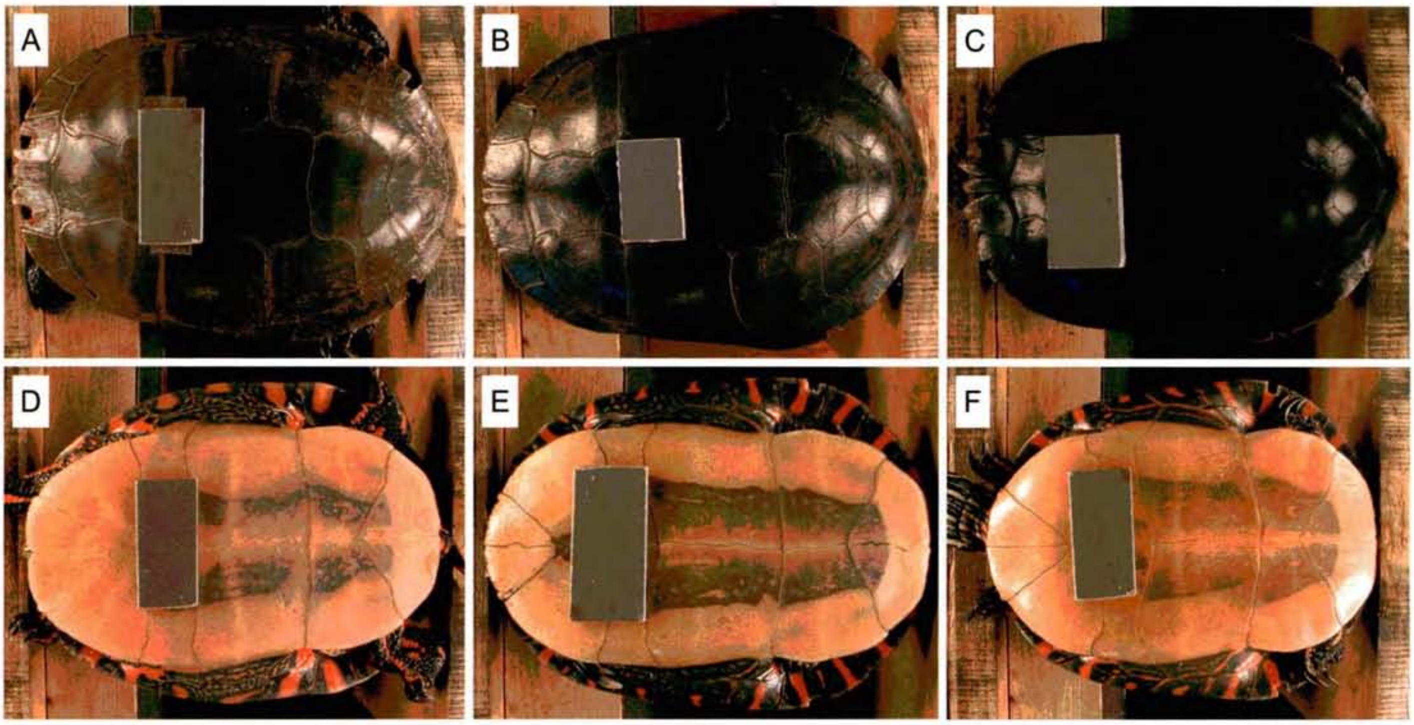

FIG. 3. Dorsal views of *Chrysemys picta* carapaces that represent mean intensity values from (A) Garden Island Harbor (light-shelled extreme), (B) Miller's Marsh (intermediate value), and (C) Welke Swamp (dark-shelled extreme) and ventral views of plastrons that represent mean intensity values from (D) Monitou Bay (light-shelled extreme), (E) Miller's Marsh (intermediate value), and (F) Welke Swamp (dark-shelled extreme).

factors, which would affect both the plastron and carapace in a similar way, affect shell color. Overall, PI was significantly but weakly related to CI (PI = 135.32 + 0.40CI, $F_{1,195} = 26.7$, $P < 0.0001$, $R^2 = 0.13$) but by a slope much less than unity ($t = 4.0$, $P < 0.0001$). A regression of the difference between PI and CI (PI - CI) on CI was significant (PI - CI = 135 - 0.61CI, $F_{1,195} = 62.9$, $P < 0.0001$, $R^2 = 0.26$) indicating that over a range of carapace intensities, dark carapaces diverged greatly from plastrons which would not be expected if exogenous factors were affecting both carapaces and plastrons.

Spectrometric analysis of shell color.—There was significant variation among all sites (Garden Island Harbor, Miller's Marsh, and Welke Swamp) in mean intensity of the third vertebral scute ($F_{2,51} = 27.0$, $P < 0.0001$, $R^2 = 0.54$). Least square mean intensity, expressed as percent reflectance, was highest at Garden Island Harbor (a light-substrate Lake Michigan harbor habitat), lowest at Welke Swamp, and intermediate at Miller's Marsh which were both inland habitats with dark substrates ($P < 0.05$ in all comparisons, Fig. 4A).

Mean intensity of the third vertebral scute, as determined from JPEG images on the same turtles that were used in the spectral analysis, varied significantly among sites ($F_{2,51} = 10.6$, $P < 0.0001$, $R^2 = 29$). Least square mean CI was greater at Garden Island Harbor than at Miller's Marsh and Welke Swamp ($P < 0.05$ in both comparisons, Fig. 4B). Intensities as determined by spectroscopy and from JPEG images were positively correlated ($r = 0.61$, $P < 0.0001$).

Mean percent reflectance of wavelengths between 330–700 nm for Garden Island Harbor, Miller's Marsh, and Welke Swamp are shown in Fig. 5. The elevation of the lines indicates differences in intensity where Garden Island Harbor turtles had the lighest shells and Welke Swamp turtles had the darkest shells. Turtles from Miller's Marsh and Welke Swamp had similar shaped curves with slight increases between 500–600 nm. Carapaces from Garden Island Harbor had lines that diverged from Miller's Marsh and Welke Swamp in the green region of the spectrum.

DISCUSSION

Using both digital image and spectrometric techniques, we detected variation in the degree of carapace darkness of *Chrysemys picta* shells among populations of the Beaver Island Archipelago. Turtles that resided in Lake Michigan harbor habitats with light-colored substrates either had relatively light carapace ground color (Garden Island Harbor) or were intermediate in the degree of darkness (Monitou Bay). In turtles from inland habitats with dark-colored substrates, turtles had either relatively dark-colored carapaces (Garden Island Inland Lake, Greene's Lake, Welke Swamp) or carapaces that were intermediate in the degree of darkness (Sorry Burn Lake and Miller's Marsh). Therefore, our prediction that turtles would show background color convergence in their respective environments seemed valid for some localities but not for others.

Pigmentation patterns of reptile integuments result from differential distribution and activity of epidermal or dermal melanophores or melanocytes that work together with other types of chromatophores to determine color quality (Cooper and Greenberg 1992). Lovich et al. (1990) suggested that in *Trachemys scripta* morphological color (long-term or permanent darkening of the integument) variation might result from hormone-mediated sup-

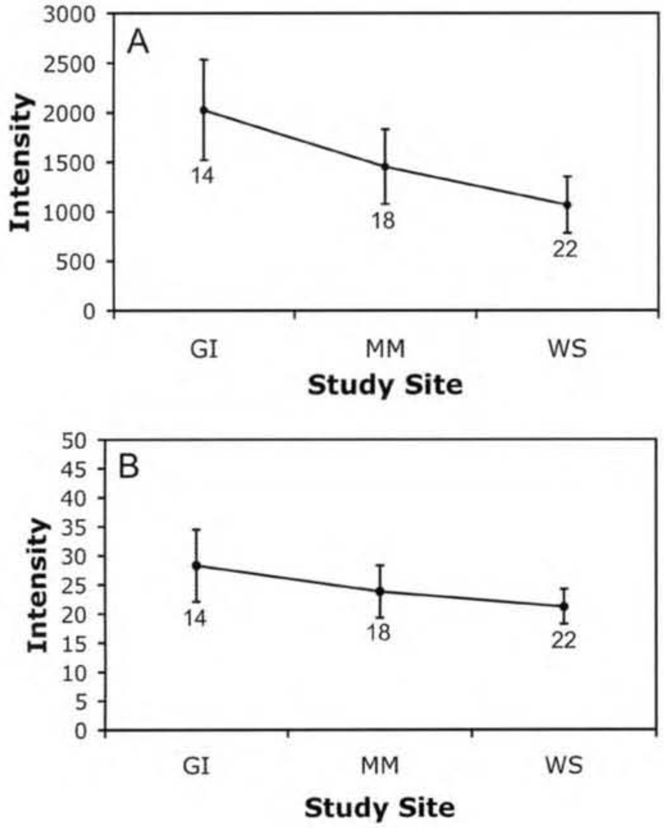

FIG. 4. Mean intensity values for the third vertebral scute of *Chrysemys picta* as determined by (A) spectrometry and (B) JPEG digital analysis for three localities. Vertical bars are ±1 SD and samples sizes are shown below.

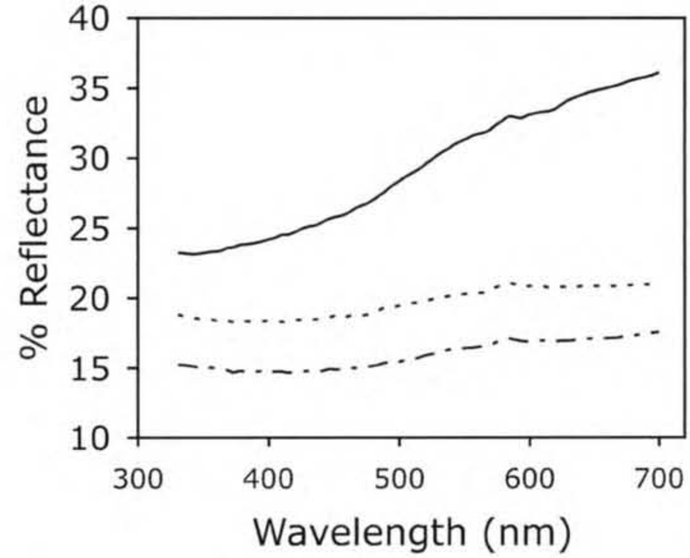

FIG. 5. Mean percent reflectance in wavelengths between 330 and 700 nm for the third vertebral scute of *Chrysemys picta* carapaces from Garden Island Harbor (solid line), Miller's Marsh (dashed line), and Welke Swamp (dot-dash line).

pression of dermal melanophores in light-colored individuals and enhancement of epidermal melanophores in melanistic individuals. A similar mechanism would presumably be operating in the closely-related *Chrysemys picta*. In our study, relatively unpigmented regions of the plastron also varied among populations in roughly the same way as that of the carapace. Such a pattern might represent plastron chromatophore activity that parallels melanophore activity of the carapace. While we cannot discount the influence of exogenous factors (e.g., tannins) on the degree of shell darkening among populations, the degree of carapace darkness strongly diverged from the plastron in dark individuals indicating that most variation in carapace darkness was due to pigment differences between individuals.

Whether the differences in carapace color among the *Chrysemys picta* populations of this study represented phenotypically plastic responses to variations in environmental conditions among habitats or fixed genetic differentiation within populations remains to be determined. Short-term increases in melanin content in the skin can be induced by dark substrate colors in some turtle species (Banks 1986; Woolley 1957) and a similar mechanism of shell color determination may exist in *C. picta*. Assuming that such plasticity would require visual input where melanin deposition is inversely related to substrate light reflection, variables such as water clarity or water depth might affect light conditions independent of substrate color (Marshall et al. 2003; Yokoyama and Yokoyama 1996). Therefore, intermediate carapace color in environments with either dark or light substrates might occur if there is variation in light transmission through water. Alternatively, it is possible that light or dark-colored turtles migrated from habitats with light or dark-colored substrates respectively to habitats with dark and light-colored substrates respectively. As a result, patterns of shell color relative to substrate color could be confounded. It is certainly possible that turtles could migrate between the dark-bottomed inland and light-bottomed Lake Michigan harbor habitats of Garden and Beaver Islands, especially through creeks and cedar swamps. However, long-distance movements away from Miller's Marsh, an inland dark-bottomed habitat on Beaver Island and with turtles with an intermediate degree of shell darkness, are not known to occur (Rowe 2003). While we cannot rule out dietary influences on color variation, we know of no instances where variation in dietary composition has been shown to cause variation in pigmentation of reptiles. Furthermore, we presume that variation in deposition of melanin, a pigment that is not directly derived from the diet (Cooper and Greenberg 1992), is primarily responsible for variation in shell intensity among individuals and populations of *Chrysemys picta*. In some reptiles, short-term darkening of the integument might be associated with enhancing heat absorption under cool conditions (Parker 1998; Pearson 1977). It is unlikely that thermal conditions of the environments of our populations had any influence on color determination as the Lake Michigan habitats, where turtles were light in color, tend to have cooler water temperatures than more inland sites (Rowe 2003; Rowe and Bowen 2005).

Acknowledgments.—We thank J.C. Gillingham and Central Michigan Biological Station for laboratory space and logistic support. M. Elliott, D. Breen, C. Zurenko, D. Vogel, helped collect turtles. Helpful comments on an earlier version of the manuscript were made by J. Macedonia. Turtles were collected under a scientific collector's permit (#1185) issued by the Michigan Department of Natural Resources Wildlife Division. Turtles were handled in accordance with IACUC standards (approval 02-07) issued through Central Michigan University.

Garman (1887) described *Phyllobates trinitatis* based exclusively on specimens from the island of Trinidad. This species was most recently transferred into the genus *Mannophryne* by La Marca (1992) after having been placed into *Prostherapis* and *Colostethus* by previous authors (*Prostherapis*—Mole and Urich 1894, Rivero 1961; *Colostethus*—Edwards 1971, Rivero 1990). It is a commonly encountered inhabitant of streams running through forests in the Northern Range and the Central Hills of Trinidad (Kenny 1969; Murphy 1997). The species description was apparently based on 20 Trinidadian specimens according to a comment at the end of the original description (Garman 1887), although not all of them may now be extant. Even though the type series (Table 1) came from Trinidad, the specific epithet *trinitatis* has also consistently been applied to coastal Venezuelan populations of rocket frogs (under the generic names *Prostherapis, Colostethus,* and *Mannophryne*) since at least the 1920s (e.g., Lutz 1927). The exception for identification of such populations as *M. trinitatis* has been the description of readily distinguishable new species (e.g., *Prostherapis neblina* Test, *P. riveroi* Donoso-Barros, *Colostethus guatopoensis* Dixon and Rivero-Blanco, *C. oblitteratus* Rivero) and the resurrection of *P. herminae* from synonymy by La Marca (1984, 1994). All other rocket frog populations throughout the

Table 1. Syntypes of *Mannophryne trinitatis* in the collections of The Natural History Museum, London (BMNH), the University of Michigan Museum of Zoology (UMMZ), and the Museum of Comparative Zoology, Harvard University (MCZ). Eight additional syntypes may exist according to Garman (1887).

UMMZ 47218	—

Venezuelan coastal range have been rather serendipitously assigned to *M. trinitatis* even after indications that this may be unwarranted.

In the early 1960s, Rivero (1961) already intimated that Venezuelan populations of *M. trinitatis* should be considered distinct from *M. trinitatis* at the species level but fell short of providing a name and a species diagnosis. In his unpublished dissertation, Edwards (1974) proposed the manuscript name "*praecia*" for a population at Cerro Azul in the Península de Paria, but this name is not available since the dissertation was never published. The distinction of Venezuelan populations was again revisited by La Marca (1994), who provided a detailed redescription of *M. trinitatis* based on Trinidadian material. Despite of the differences noted between Venezuelan and Trinidadian specimens, La Marca (1994) initiated no taxonomic change. In his online database, Frost (2004) shows the distribution of *M. trinitatis* as restricted to Trinidad. This restriction first appeared online in the version of the database posted in 2000, but without analysis or further explanation. Kaiser et al. (2003) described inconsistencies between rocket frogs from Trinidad (referred to as *M. trinitatis*) and Venezuela (referred to as *M.* cf. *trinitatis*) at the chromosomal level, providing a data set independent of the morphological information to confirm the assertion that Trinidadian and Venezuelan populations, at least from the Caracas area, are distinct.

We believe that the combined morphological and chromosomal evidence now clearly supports the hypothesis that the distribution of *M. trinitatis* includes only the island of Trinidad. Even though the information posted on the webpage for *M. trinitatis* in Frost's (2004) *Amphibian Species of the World* database indicates that the species is restricted to Trinidad, and has done so since an earlier version in 2000, this information has not entered the literary mainstream. We presume that this may be because *Amphibian Species of the World* is an online-only reference that does not provide the data used to arrive at the decision to restrict the distribution of the species. As a consequence, authors have continued to report *M. trinitatis* from Venezuela (e.g., Barrio-Amorós 1998, 2004; Manzanilla and La Marca 2005). The proper application of the name *M. trinitatis* to the correct populations is of considerable importance, not only from the point of taxonomy or biogeography, but especially since isolated populations in Venezuela have been given the IUCN Red List status of vulnerable (IUCN et al. 2004).

Unfortunately, there is no name available that could be applied to the coastal Venezuelan populations of these commonly encountered rocket frogs. Populations throughout the Venezuelan Cordillera de la Costa and other coastal habitats, however, require additional sampling and further study to ascertain how many species have been hiding under the improperly applied name *M. trinitatis* for the better part of a century.

Acknowledgments.—We thank Jason Trujillo for his assistance and companionship in the field. This project was funded by a grant from the College of Arts and Sciences of La Sierra University to HK.

Subcutaneous Movements of Visible Implant Elastomers in Wood Frogs (*Rana sylvatica*)

DEANNE L. MOOSMAN

Concerns about declines in amphibian populations have increased the need for long-term studies of amphibians (McCoy 1994). These studies often require methods of marking that are readily applied, safe for the organism, and allow reliable identification (Nace 1982). Marks should: 1) not effect mortality rates or behavior; 2) allow identification of individuals; 3) be permanent; and 4) be easily interpreted (Ricker 1956). Toe clipping is commonly used to mark amphibians but may alter feeding behavior, reduce potential for weight gain, cause infection, and toes may regenerate (Clarke 1972; Davis and Ovaska 2001; Ferner 1979; Golay and Durrer 1994). Passive Integrated Transponders (PIT) tags are useful in marking amphibians for long-term studies, however the process of tagging can be time-consuming, materials are expensive, and some animals may be too small for the technique (Ireland et al. 2003; Ott and Scott 1999). Visible Implant Elastomers (VIE; see Anholt et al. 1998; Bailey 2004; Davis and Ovaska 2001; Marold 2001; Nauwelaerts et al. 2000) are long lasting and allow many individuals to be marked (Northwest Marine Technology 2000). Several colors, which fluoresce under blue light, can be injected at various body locations, providing hundreds of unique marks. Another subcutaneous marking technique, alpha numeric fluorescent tags, may have similar advantages over traditional methods (Buchan et al. 2005).

Retention of VIE marks has been studied in *Rana esculenta* (Nauwelaerts et al. 2000), *Plethodon vehiculum* (Davis and Ovaska 2001), *Eurycea bislineata* (Bailey 2004; Marold 2001), and *Desmognathus fuscus* (Marold 2001). Although these studies found that marks were retained, further information is needed on the potential subcutaneous movements of marks away from their original locations. In a laboratory study, Marold (2001) used 14 mark locations on *Eurycea bislineata* and found marks in the mid-body region were easily confused with those in surrounding locations. Davis and Ovaska (2001) marked *Plethodon vehiculum* on six ventral surfaces and noted that 13 of 69 (19%) individuals were difficult to identify due to subcutaneous movements of marks. Bailey (2004) found that observers misidentified *E. b. wilderae* on 39 of 300 (13%) occasions. Our study objectives were to: 1) determine if subcutaneous movement of marks varied depending on where in the body they were applied; and 2) identify optimal regions for marking wood frogs (*Rana sylvatica*).

Twenty-four (23 males and 1 female) adult *Rana sylvatica* were collected on 29 January 2001 at a breeding pond in Madison County, Kentucky, USA. In the laboratory, five frogs were placed into each of four tanks, with four frogs in an additional tank. Each 37.9 L tank contained pebble and soil substrate and a water dish. Tanks were watered daily to ensure moist conditions and temperature was maintained at 20°C. Frogs were inspected for mortality and infection daily and were fed crickets weekly.

Each frog was marked in two regions of the body by injecting VIE under the skin. Six injection sites were tested: the centers of the dorsal and ventral aspects of the forelimb, mid-body, and hindlimb (Fig. 1). Borders of each body region were defined by proximal ends of the limbs and dorso-ventral midlines of the body (Fig. 1). Frogs were not anesthetized and were hand-held during injections. Individuals in each tank were marked in the same combination of body regions, including: tank 1 - ventral surfaces of the mid-body and hindlimb; tank 2 - ventral surfaces of the mid-body and forelimb; tank 3 - dorsal surfaces of the mid-body and hindlimb; tank 4 - dorsal surfaces of the mid-body and forelimb, and; tank 5 - contained one individual from each of the four marked groups.

Frogs were marked on 1 February 2001, and positions of VIE were monitored weekly until 2 March 2001. Marks were inspected using a flashlight with blue light emitting diodes, while wearing

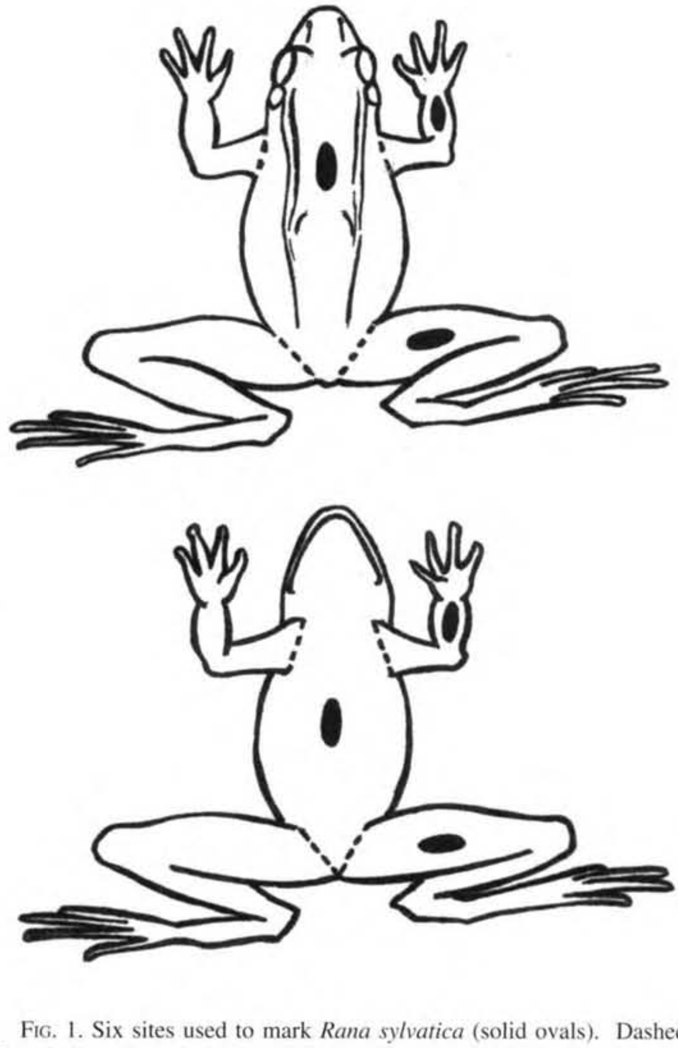

FIG. 1. Six sites used to mark *Rana sylvatica* (solid ovals). Dashed lines indicate boundaries between dorsal and ventral forelimbs, midbody, and hindlimbs.

TABLE 1. Percentages of Visible Implant Elastomer marks that exhibited subcutaneous movements out of assigned body regions (N) in captive *Rana sylvatica*.

	Forelimb (12)	Midbody (24)	Hindlimb (12)	Overall (48)
Dorsal	17	0	0	6
Ventral	0	100	33	44
Overall	8	50	17	—

filter glasses (Northwest Marine Technology) that only permitted green, yellow, orange, and red colors to be viewed. Positions of marks were scored as '0' if they were within defined borders of the marked region, or '1' if they were outside of or touched the borders of the marked region (Fig. 1). Effects of location (forelimb, mid-body, or hindlimb) and aspect (dorsal or ventral) on fidelity of marks to defined body regions were determined at the end of week four using two Chi-square contingency tables at $\alpha = 0.05$ (Zar 1999; SPSS 13.0). A multi-dimensional contingency table was not used because average expected frequencies were < 6 (Zar 1999).

Fifteen of 48 marks (31%) exhibited subcutaneous movements. Movements of marks occurred non-randomly with respect to location ($\chi^2 = 8.05$, $P < 0.018$, d. f. = 2) and aspect ($\chi^2 = 16.39$, $P < 0.001$, d. f. = 1). Marks on limbs and the dorsal aspect showed fewer subcutaneous movements than mid-body and ventral marks (Table 1). Although we did not test for an interaction between location and aspect, marks in some body regions showed relatively high percentages of subcutaneous movements. Specifically, all marks on the ventral mid-body exhibited subcutaneous movements; whereas, all marks on dorsal mid-body and hindlimb, and ventral forelimb remained in defined regions (Table 1). No injuries, infections, or mortalies occurred over the one-month study.

Our results indicate that Visual Implant Elastomers may not be useful in the dorsal forelimb, ventral midbody, and ventral hindlimb of *Rana sylvatica*. Researchers that assign marks in these regions may misinterpret mark combinations. Other regions (dorsal midbody and hindlimb, and ventral forelimb) may be more suitable for marking ranids. Several factors may have contributed to differential mark fidelity, including: how deeply marks were injected, degree of connectivity between skin and underlying muscle, abrasion with substrate, and handling by researchers (frogs were restrained by grasping the mid-body and hindlimbs). On several occasions, we observed that marks moved as a result of handling. Northwest Marine Technologies (2000) recommended handling specimens with care for at least ten days after tagging. If specimens are handled excessively before elastomers cure, marks may be forced out the needle wound (Northwest Marine Technology 2000). Loss of marks did not occur during our study, although subcutaneous movements of elastomers were observed within the first week after injection. On two occasions, marks appeared to be lost when they moved behind dark pigment; the marks became visible again after moving to areas with lighter pigmentation. Additionally, we had difficulty differentiating between red and orange marks, particularly when they were behind pigmented areas.

Our study was limited to four weeks under laboratory conditions; long-term field studies may be needed to determine the overall efficacy of using VIE for marking ranids. Conditions or behaviors in the field (e.g., amplexus, burrowing, or abrasion with substrate) also may result in differential mark movement. Likewise, movement of marks behind dark pigment may increase chances of misinterpreting colors or failing to detect marks. Unfortunately, except for the ventral forelimb, regions with the highest mark fidelity also had the darkest pigmentation (i.e., dorsal regions). Conceivably, other subcutaneous marking methods (alpha numeric fluorescent tags) may suffer from similar problems. We recommend that researchers avoid applying marks in neighboring body regions or those with low mark fidelity. In some cases, it may be necessary to avoid marking densely pigmented regions.

Acknowledgments.–We thank Peggy Hoppe for assistance with injections of the VIE, and Paul Cupp and Anthony Guarino for assistance with data analyses and manuscript preparation.

Buchan et al. (2005) considered their testing of alphanumeric fluorescent tags (VIAlpha tags) to mark frogs and salamanders to be a first for amphibians. However, previously we reported the successful use of these tags in the Indian caecilian *Gegeneophis ramaswamii* in both the laboratory (Measey et al. 2001) and field (Measey et al. 2003a). Our aims here are to compare use of VIAlpha tags in different amphibians now that they have been tested in representatives of all three orders, and to draw attention to other recent progress in caecilian ecology.

Measey et al. (2001, 2003a) both made incisions and inserted VIAlpha tags using only the manufacturer's supplied injector. Buchan et al. (2005) made incisions with a blood lance and used the injector only to deliver the tags. On a subsequent visit to the study site reported by Measey et al. (2003a), we also used a blade (scalpel) to make the initial incision in *G. ramaswamii*, obviating the need to resharpen the injector. This reduced tagging time from up to 5 mins (Measey et al. 2001) to less than 1 min per individual. This is still longer than that reported for frogs and salamanders by Buchan et al. (2005), perhaps because caecilians have annulated bodies with a tighter connection between the skin and external muscular sheath (Nussbaum and Naylor 1982).

Buchan et al. (2005) did not anaesthetize frogs and salamanders, whereas Measey et al. (2001: table 1) asserted that inserting tags into caecilians requires anaesthesia. Restraining caecilians in the hand is difficult so that tagging precision is impractical without anaesthesia, something that might also be expected for some salamanders. Unlike Buchan et al. (2005), we did not sterilize equipment before tagging each individual at our site, but we recognize that this represents best practice. Equipment should also be sterilized before use in other sites to prevent spread of pathogens (e.g., Fellers et al. 1994).

Caecilian biology in general remains much less known than for frogs and salamanders (Gower and Wilkinson 2005). Despite this, much progress has been made recently in quantitative caecilian ecology, including studies of abundance (Measey 2004; Measey et al. 2003a, b), condition (Measey and Gower 2005), niche separation (Gower et al. 2004), diet (Jones et al. 2006; Kupfer et al. 2005a; Measey et al. 2004), and life history (Kupfer et al. 2004, 2005b; Malonza and Measey 2005).

Acknowledgments.—Assistance in the field was provided by R. Janardhanan, S. Vishvambaran, and S. Mathew. G. J. Measey made useful contributions to earlier manuscript drafts. This research was supported by the Zoological Research Fund of the Natural History Museum, London (DJG, MW), and a seed grant from the Declining Amphibian Population Task Force (OVO).

Effects of Tricaine Methanesulfonate (MS-222) Concentration on Anesthetization and Recovery in Four Plethodontid Salamanders

WILLIAM E. PETERMAN
and
RAYMOND D. SEMLITSCH
Division of Biological Sciences, University of Missouri-Columbia
Columbia, Missouri 65211-7400, USA
e-mail: WEPeterman@mizzou.edu

Tricaine methanesulfonate (also known as MS-222, Tricaine, Metacaine, or ethyl *m*-amino-benzoate methanesulfonate) is a commonly used anesthetic for fish and amphibians. Previous research has shown that the pH of MS-222 solutions has an effect on anesthetic efficacy and physiological functions (Letcher 1992; Lowe 2004; Ohr 1975a,b; Robinson and Scadding 1983). Current recommendations are to buffer solutions of MS-222 to a neutral pH (Crawshaw 1993; Robinson and Scadding 1983; Ohr 1975a). MS-222 solutions can be buffered using $NaHCO_3$ (sodium bicarbonate; Cooper 2003), aqueous buffers such as dihydrogen potassium phosphate and sodium hydroxide (Lowe 2004), or can be titrated with NaOH (Ohr 1975a). Although MS-222 is widely used and the benefits of buffering solutions are well known, few studies elaborate on the effects of its concentration on amphibian anesthetization and subsequent recovery time (see Letcher 1992; Robinson and Scadding 1983). We assessed the effects of MS-222 (Sigma, catalogue number A5040-25G) concentration in aqueous solutions on the time to anesthetization and recovery. Four species of semi-aquatic, stream-breeding salamanders (*Desmognathus monticola*, *D. ocoee*, *D. quadramaculatus*, and *Eurycea wilderae*) were tested at three different concentrations (500 mg/L, 1000 mg/L, and 2000 mg/L).

Materials and Methods.—We used 45 salamanders per species for this experiment. Animals were housed with moist paper towels in plastic Gladware™ containers (15.5 × 15.5 × 5 cm) within an environmental chamber on a 12/12 light cycle at 20°C and 75% humidity. Depending upon the species and size of the salamanders, 2–10 animals were kept together in the same container. No salamander was held in the environmental chamber for more than 72 h prior to testing. Fifteen salamanders per species were tested at each of three experimental concentrations (500 mg/L, 1000 mg/L, and 2000 mg/L) of MS-222. Salamanders were tested only once, at one concentration to ensure independence between replicates. After testing, all salamanders were returned to the environmental chamber for at least 24 h before being returned to their stream of capture. Solutions were made using 0.250 g, 0.5 g, and 1.0 g of MS-222 dissolved in 500 ml of distilled water. Solutions had an instantaneous pH of 3.9–2.8, and were neutralized with varying amounts of sodium bicarbonate (0.4 g for 500 mg/L to 0.93 g for 2000 mg/L), added in small amounts while monitoring the pH with a pH meter (Oakton Instruments, product # 35624-33). Solutions were buffered to a pH of approximately 6.5 as the pH would continue to rise throughout testing.

To test the effects of concentration, salamanders were submerged in the MS-222 solution and the time to complete anesthetization was recorded. An animal was deemed anesthetized (the induction time, Robinson and Scadding 1982) when unable to right itself and reflexive and voluntary responses to gentle pinching of the limbs and tail with forceps ceased. Salamanders were then rinsed in pure distilled water and laid in a shallow dissecting tray with distilled water (partially submerging the animal). Salamanders were monitored with gentle pinching of the limbs until a response was detected. Two to three salamanders were tested in the MS-222 solution at a time, being replaced by others after induction. Solution mixtures were used repeatedly until the pH rose above 8. There was a 45 minute cut-off for induction, after which animals were removed from the MS-222 solution and omitted from the data set. The mean body mass, mean pH, mean temperature, mean induction time, mean time to recovery, and all standard errors were calculated. Analyses of covariance (ANCOVA, SPSS v.13) were run for each MS-222 concentration, comparing species to induction and recovery time, with mass as the covariate. All factors were log transformed. Tukey-Kramer's multiple comparisons tests were run to identify significant species differences based on induction and recovery times.

Results.—Induction time generally decreased and time to recovery increased with increasing MS-222 concentration (Table 1). The smaller salamanders, *D. ocoee* and *E. wilderae*, closely followed this pattern with little variation. The larger two species, *D. quadramaculatus* and *D. monticola*, exhibited the most variation in both induction and recovery times. Most notably, *D. quadramaculatus* had a substantially longer recovery time at 1000 mg/L than either the 500 or 2000 mg/L concentrations. It was found that species differences were highly significant ($P<0.001$) at all concentrations for both induction and recovery times. Tukey-Kramer's multiple comparisons showed extreme variability in species differences both between concentrations and between induction and recovery times. The covariate mass was significant for both the 500 and 2000 mg/L concentrations ($F_{1,57} = 6.39$, $P = 0.014$; $F_{1,54} = 7.84$, $P = 0.007$ respectively). Contrary to the low and high concentrations, mass was not significant in the 1000 mg/L concentration ($F_{1,59} = 0.095$, $P = 0.760$). Mass was also not significant in relation to recovery time for any MS-222 concentration, though was nearly significant in the anomalous 1000 mg/L concentration ($F_{1,59} = 3.62$, $P = 0.062$). We had 100% survival of all tested salamanders at all concentrations and no abnormal behavior or visible external impairments were incurred as a result of testing. The temperature of aqueous MS-222 solutions was held constant (mean temperature = 26.9°C, SE = 0.061, N = 173) and the pH was kept neutral (mean pH = 7.15, SE = 0.020, N = 173).

Discussion.—Increasing the concentration of MS-222 in a neutral solution led to shorter induction times and longer recovery times. These results correspond to those found by Robinson and Scadding (1983) and Letcher (1992). As concentration increased, variation in induction time within species generally decreased, while variation in recovery time generally increased. The larger salamander species, *D. quadramaculatus* and *D. monticola*, generally took longer to reach complete induction than the smaller *D. ocoee* and *E. wilderae* (Table 1). *Desmognathus monticola* was the most anomalous species tested, showing no consistent pattern between concentrations, and many individuals did not become inducted within the 45 minute cut-off (note sample sizes in Table 1). For its size, *D. ocoee* reached induction more slowly and re-

TABLE 1. Mean and standard error (±SE) estimates of body mass (g), induction time (min), time to recovery (min), pH, and temperature (°C) for each species in each MS-222 concentration (mg/L).

	Mass	Induction	Recovery	pH	Temperature
D. quadramaculatus

2000 (N = 10)	4.61 (±0.57)	8.29 (±1.77)	7.43 (±0.95)	7.13 (±0.08)	27.00 (±0.33)
D. ocoee					
500 (N = 15)	0.82 (±0.99)	12.73 (±1.86)	3.67 (±0.24)	7.00 (±0.00)	26.00 (±0.00)
1000 (N = 15)	0.83 (±0.12)	4.60 (±0.27)	6.96 (±0.35)	7.30 (±0.00)	27.00 (±0.00)
2000 (N = 15)	0.67 (±0.09)	2.35 (±0.08)	9.72 (±0.78)	7.35 (±0.00)	28.00 (±0.00)
E. wilderae					
500 (N = 15)	0.61 (±0.10)	4.70 (±0.31)	8.50 (±0.36)	7.14 (±0.02)	26.60 (±0.13)
1000 (N = 15)	0.59 (±0.10)	2.36 (±0.12)	14.12 (±0.56)	7.35 (±0.09)	27.00 (±0.00)
2000 (N = 15)	0.71 (±0.07)	1.90 (±0.13)	21.54 (±1.15)	6.91 (±0.00)	26.00 (±0.00)

covered faster than expected in 500 mg/L. *Desmognathus quadramaculatus* also exhibited unexpected variation in its recovery time in the 1000 mg/L concentration.

Contrary to Lowe (2004), mass played a significant role in time to induction in two of the three concentrations (500 and 2000 mg/L), although mass was not significant in time to recovery in any concentration. But in accordance to Lowe (2004), species differences were most significant (P<0.001) and present in all concentrations for both induction and recovery times, but the inconsistency of significant differences between species attests to the variability within this system. The latter may be indicative of a phylogenetic variation (Lowe 2004), but other factors influencing the induction and recovery times of salamanders may include the time since last feeding, age, sex, and reproductive status.

It was our goal to provide information for practical and efficient use of MS-222. Researchers should choose the most appropriate concentration for their needs of handling or operating upon salamanders. At 1000 and 2000 mg/L induction times for all species were 6 minutes or less, making recovery time the most important consideration when selecting a concentration in which to anesthetize salamanders. If longer recovery times are required, animals can be left in MS-222 solutions for an extended period of time beyond the time of last response with no fatal effects (Robinson and Scadding 1983; pers. obs.), although this has not been explicitly tested. Higher concentrations of MS-222 may cause some physiological stress (Robinson and Scadding 1983) and should be avoided if possible.

Although all of these salamander species share similar life history characteristics and three are congeners, extensive variation was present. Preliminary testing of species' responses to MS-222 is recommended. For more control over the pH of a solution, we also recommend following buffering procedures described by Lowe (2004) or Robinson and Scadding (1983). Further, for extended anesthetization, intraceolomic injection may be preferred (Letcher 1992).

Acknowledgments.—All procedures were approved by the University of Missouri Animal Care and Use Committee (protocol #3951). Salamanders were collected under USFS permit number HIG 6493. We thank Highlands Biological Station for laboratory facilities, and Tim Altnether and John Crawford for assistance in collection of salamanders. Valued comments were provided by John Crawford, Andrew Cox, Thomas Pauley, Jason Lowe, and Deanna Olson.

Feasibility of Using Plastron Markings in Young Wood Turtles (*Glyptemys insculpta*) as a Technique for Identifying Individuals

SUSAN COWIN

Being able to recognize individual animals is important in studies of behavior, movements, social structure, population and density estimates, growth rates, as well as survival and mortality estimates. According to Godley et al. (1999) these parameters are essential for the conservation and management of threatened or endangered species.

Traditionally, shell notching has been the main method of marking turtles for identification of individuals (Cagle 1939). In recent years, use of PIT (Passive Integrated Transponder) tags has gained popularity (Godley et al. 1999). While use of PIT tags is non-mutilating, it is still invasive and tags can be too large to implant in hatchlings (Buhlmann and Tuberville 1998) or small juveniles. Similarly, notching an adult turtle's carapace can be relatively quick and easy, but notching hatchlings and juveniles is more difficult and can cause serious shell fractures (Cagle 1939).

The use of natural markings as a means to identify individuals is growing, especially where the animal being studied is secretive (Karanth 1995; Karanth and Nichols 1998), where tag loss is reportedly high (McDonald and Dutton 1996) or where traditional methods of capture to obtain information are not feasible due to threat of harm to the animal (Bretagnolle et al. 1994; Stevick et al. 2001). Some studies of turtle populations have used photocopies or digital photographs of turtle plastron markings as a means of identifying individuals (Janzen et al. 2000a; Janzen et al. 2000b; Kolbe and Janzen 2001).

In order for natural markings to be of value to long-term population studies, it is crucial that they are stable over time and change very little throughout an animal's life (Vincent et al. 2001); the probability of correctly identifying an individual decreases if the pattern changes over time. Hatchling Wood Turtles (*Glyptemys insculpta)* do not hatch with their characteristic black plastron patterns. Instead, the plastrons of newly hatched Wood Turtles are a tawny brown with darker brown flecking. The purpose of this study was to determine if the plastral markings of Wood Turtles change as hatchlings mature and to evaluate the use of digital photographs of plastron markings as a non-mutilating, non-invasive technique for the identification of individuals.

This study was carried out from February 2004 to February 2005 with a group of 24 captive Wood Turtles that hatched in the late summer of 2003. These turtles are part of a head-starting program run by the Ontario Ministry of Natural Resources and the Kawartha Turtle Trauma Centre, in Peterborough, Ontario. Hatchlings were housed in large Rubbermaid containers and separated out according to clutch; clutches were not mixed. In total, there were five separate tanks, one with three turtles (W4), one with eight turtles (W1), one with five turtles (W3b) and two with four turtles each (W2, W3a).

In order to track mortality, weight gain and growth of the hatchlings, volunteers caring for the Wood Turtles had to be able to recognize the individual turtles. Initially, a non-toxic, formaldehyde-free nail polish was painted on the turtles' marginal scutes in individual patterns according to Cagle (1939). Starting in February 2004, digital photographs were taken of each turtle's plastron and a photograph was also taken of the carapace if the turtle had any noteworthy abnormalities. Digital photographs were used primarily for identifying individuals (with the nail polish markings becoming the back-up to the photographs) until the volunteers began to notice that the plastron markings were changing, making identification by the photographs alone more difficult. Photographs of plastron patterns were updated in April, August, and November 2004, with the final set being taken in February 2005. Photographs were used as back up for the nail polish markings as well as to determine the extent to which the patterns changed over time. All photographs were edited in Adobe Photoshop CS to make them the same size, and contrast levels were adjusted; no other alterations of the photographs or the plastron markings were made (Fig. 1).

In order to determine if the plastron patterns changed over time as the turtles grew, 10 volunteers were shown a catalogue of photographs of the turtles and then asked to find the match for a picture taken at a later time. Pictures of 10 turtles were chosen at random from 24 possibilities and these were the ones used for this part of the study. The catalogue represented turtles that had been photographed at a previous time and the pictures of the turtles given to the volunteer were more recent shots of the catalogued turtles. All ten of the 'baby photographs' were laid out in front of the volunteers; they were then given one photo at a time of the pictures that were taken at a later date to match to the earlier photograph. This was repeated until each volunteer had attempted to match all ten turtles to their 'baby' pictures. Volunteers were provided with a best case scenario: the turtles they were given were included in the catalogue of the ten pictures. Volunteers were not timed, to avoid adding pressure. Volunteers were not told if they had chosen correctly or incorrectly to avoid matches being made by a process of elimination.

The first trial involved photographs taken in February 2004, when the turtles were 6 months old, and photographs taken in February 2005, when they were 18 months old. The second trial was conducted in the same manner as the first trial, but used the photographs taken at 12 months of age to compare to those taken at 18 months.

In the first trial the rate of success for correctly matching a picture of the plastron pattern of a test Wood Turtle to the same turtle taken a year earlier was only 29%. There were three instances in the first trial where the volunteers were unable to pick any of the pictures in the catalogue as the one they had in their hand. For the second trial when the catalogue turtles were a year old and the test photos were of 18 month old individuals, the rate of success for correctly matching the turtles was increased to 67%. Volunteer experience ranged from no experience with turtles to being experienced with handling turtles on a regular basis. Seven volunteers mismatched siblings from clutch W4 in at least one of the two trials.

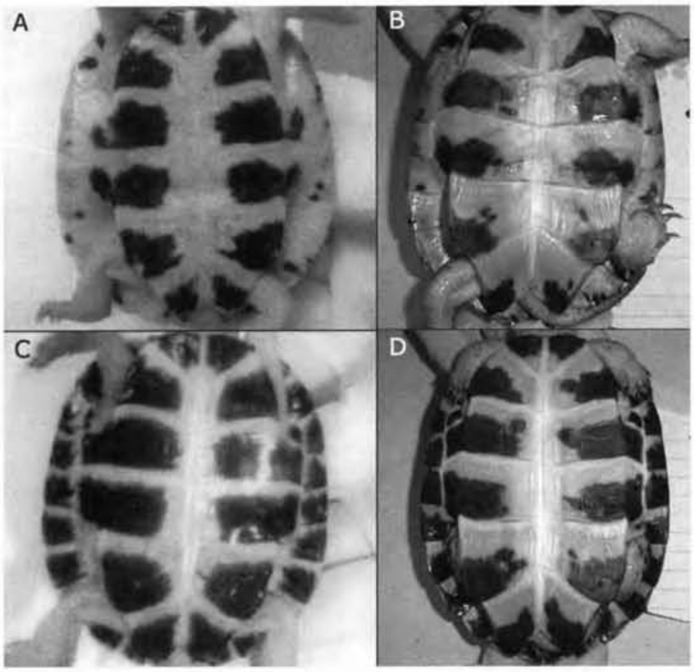

FIG. 1. Digital photographs of the plastrons of juvenile *Glyptemys insculpta*. a) Turtle W1.6 in February 2004 and b) in February 2005. c) Turtle W3.2a in February 2004 and d) in February 2005.

The stability of natural markings over time is essential if they are going to be used for long-term population studies (Vincent et al. 2001); the probability of correctly identifying an individual decreases if the pattern changes over time. Many naturally distinctive markings remain relatively unchanged over an animal's life and prove to be a reliable source of identification. McDonald and Dutton (1996) photographed the pineal (pink) spots of nesting leatherback marine turtles (*Dermochelys coriacea*) to develop life history profiles and size estimates of nesting populations. They discovered that for leatherbacks, photo-identification was a more reliable means of recognizing individuals than was the use of flipper tags. A high success rate with using natural markings has also been found for spotted salamanders (Loafman 1991), tigers, manatees, and many other animals (Karanth and Nichols 1998; Langtimm et al. 1998).

This study looked at the stability of plastron markings in the endangered Wood Turtle (*G. insculpta*) and evaluated the feasibility of using the plastron markings as a means of identifying very young individuals as an alternative to notching or toe clipping. The volunteers matching the plastron patterns on pictures that were taken a year apart had a great deal of difficulty in doing so; the average percentage of correct matches in the first trial was 29%. Volunteers frequently commented on how difficult it was to match pictures taken in February 2005 to those taken in February 2004. A frequent error made during matching was the mistaking of clutch mates for one another as it was found that they often resembled each other in patterning. In the second trial, volunteers still commented on how difficult it was to match the correct picture to one taken 6 months previously, despite a doubling in the rate of successful matches. The rate of success for correctly matching a test turtle from February 2005 to catalogued pictures that were taken in August of 2004 was 67%. The higher success rate in the second trial suggests that markings become more stable as Wood Turtles mature. For other species, including the Box Turtle, the plastron markings appear to become set for life once a turtle reaches subadult size (C. Swarth, pers. comm.).

The purpose of this study was to determine if the plastron patterns of Wood Turtles changed as hatchlings grew and to determine if the plastron markings could be used as a means to identify individual hatchlings over time. The appeal of this technique is that it is less invasive and mutilating than either filing or cutting notches into the marginal scutes or toe clipping. Unfortunately, it does not appear as though the use of plastron markings will be a useful stand-alone technique in the field for identifying individual hatchlings over time; the markings are too unstable and change too much while the turtles are growing.

Acknowledgments.—We thank all the volunteers who helped take the pictures and those who took the time to match plastron photos: Tara De Blois, Steve Sharpe, Regina Varrin, Toby Wells, Malcolm Shepard, Kearsley Schieder-Wethy, Dawn Fidler, Lauren Hughes, and Anne Kidd. We thank all the researchers, zoologists, and herpetologists who took the time to answer our emails and share their findings (published and unpublished) and especially to the volunteers at the Kawartha Turtle Trauma Centre. Thanks also to Erica Nol for comments on the manuscript. Care of the turtles was covered by Ontario Ministry of Natural Resources Authorization to Keep Specially Protected and Game Wildlife in Captivity permit #1026097.

A Note on Effective Basking Trap Size

SUSAN L. TRAN

Basking traps are an effective means of capturing many species of turtles and commonly used in field research (Gibbons 1990; Lindeman 2000; McKenna 2001). However, there is little published information about the relative efficacy of different basking trap sizes. Practical considerations of costs, handling and storage favor smaller traps but we suspected that larger traps were more effective in capturing turtles. Thus we modified a basking trap design that was developed by McKenna (2001), to include both large and small versions for tests in a field study.

All traps were made of a floating, square frame with a mesh basket suspended underneath the frame. Small traps were constructed of 5.1 cm diameter polyvinyl chloride (PVC) pipe, joined with PVC elbows to form a 0.71×0.71 m floating frame. Large traps were constructed of 10.2 cm diameter PVC pipe, joined with PVC elbows to form a 0.93×0.93 m floating frame. Frames pipes were packed with buoyant, closed-cell plastic foam. Baskets had depths ≥ 18 cm and were made of plastic, garden mesh fencing (5.08×5.08 cm) attached to the floating frames with plastic cable-ties. Ramps were constructed from plastic (polyethylene) landscaping lattice, cut into rectangles of the same width and approximately half the length of the traps, and attached on two, opposite sides of the floating frames with cable ties. Ramps extended from the top of the frames into the surrounding water on the outside of each trap. Turtles climb up the ramps to bask and are trapped when they fall or jump inside the floating frame.

We conducted our field test of trap size in the Ottawa National Wildlife Refuge, Ottawa County, Ohio, USA (41°37'N, 83°12'W). The refuge consists of diked marshes separated by deeper channels used to control water levels. Ten traps of each size were set in both marshes and channels, and checked about every third weekday between April 26 and July 21, for an average total of 44 trapping days per trap. A total of 191 turtles were captured (*Chrysemys picta*: 97 female adults, 38 male adults, 2 juveniles; *Graptemys geographica*: 32 female adults, 15 male adults, 5 juveniles; *Trachymus scripta elegans*: 2 males), including 51 recaptures (*C. picta*: 25 female adults and 6 male adults; *G. geographica*: 7 female adults, 11 male adults, and 1 juvenile; *T. s. elegans*: 1 male).

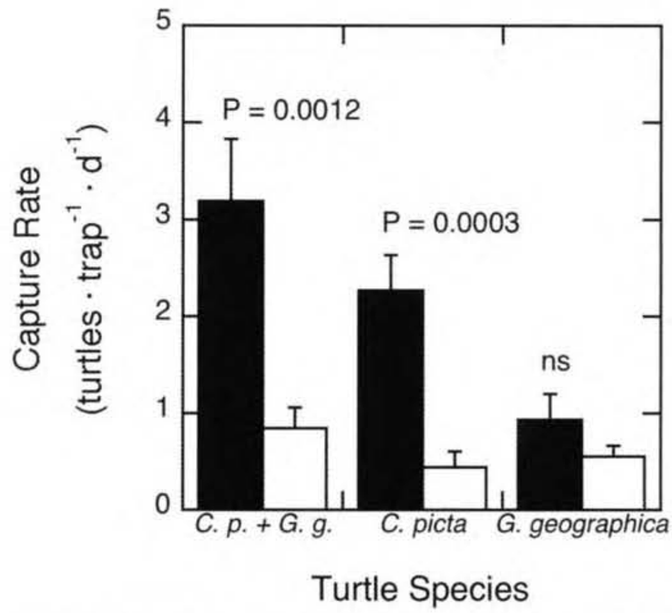

FIG. 1. Trap success for large (black bars) and small (white bars) traps evaluated with Wilcoxon Sign Rank tests for *Chrysemys picta*, *Graptemys geographica*, and both species combined. Error bars represent one standard deviation.

We estimated trapping success as the number of turtles captured per trap per day (turtles • trap^{-1} • day^{-1}) to correct for variations in trapping periods for individual traps, due to occasional drift or wind damage. A Wilcoxon Sign-Rank test used this measure of daily trap success as the dependent variable for comparing mean capture rates for the two trap sizes (SAS version 8.0). Large-framed traps caught significantly more turtles than small-framed traps (Fig. 1) for *C. picta* ($P = 0.003$), and for both species combined ($P = 0.012$), but not for *G. geographica*. Hence, the convenience and monetary savings of small traps is offset by a reduction in their apparent capture effectiveness for at least some species.

Acknowledgments.—This research was made possible by the cooperative efforts of the US Fish & Wildlife Service, Ottawa National Wildlife Refuge, University of Toledo, Department of Earth, Ecological, and Environmental Sciences, and the Lake Erie Research and Education Center and was supported, in part, by the University of Toledo Summer Research Award and Fellowships program and the National Science Foundation Research Experience for Undergraduates program (Grant # SES-0243872). The authors have complied with all applicable institutional Animal Care guidelines and have obtained all state and federal permits in order to conduct this research.

The Relative Efficiency of Basking and Hoop Traps for Painted Turtles (*Chrysemys picta*)

TONY GAMBLE
Conservation Biology Graduate Program, University of Minnesota
100 Ecology Bldg, 1987 Upper Buford Circle
St. Paul, Minnesota 55108, USA
e-mail: gambl007@umn.edu

Trap efficiency, the rate at which a trap catches animals (Novak 1987), is an important factor when gathering quantitative data such as relative abundance. Different techniques may catch individuals at different rates making comparisons across studies difficult or impossible (Heyer et al. 1994). Different trap types may also capture classes of individuals at different rates and lead to an over or under representation of animals of a specific age, size or gender (Frazer et al. 1990; Koper and Brooks 1998; Ream and Ream 1966). Increasing trap efficiency is an important way to increase the precision of population size estimates from mark-recapture data. The precision of population size estimates is increased as a higher proportion of the population is captured and marked (Seber 1982) which will be achieved more readily using a maximally efficient trapping method. Efficient trapping is also important to researchers trying to maximize return for their effort in terms of time and money (Morton et al. 1988).

Several methods exist for trapping aquatic turtles but there have been few studies comparing the relative efficiency and practicality of different trap types. The two trap styles commonly used to capture aquatic turtles are basking traps and hoop traps. Basking traps, as the name suggests, take advantage of the basking behavior of turtles. There are several basking trap designs and most consist of a basking platform with a net or wire basket attached underneath. Turtles are captured in the net after leaving the platform. Hoop traps consist of a cylindrical frame covered in mesh; turtles, attracted by bait, enter the trap through a submerged, funnel-shaped opening. Lagler (1943) claimed that hoop traps were "the most efficient and practical kind of trap for turtles" although he offered no evidence for this claim. Basking traps have been shown to be more effective than hoop traps in capturing Map Turtles (*Graptemys geographica*) and Painted Turtles (*Chrysemys picta*) although both studies examined only single populations (Browne and Hecnar 2005; McKenna 2001). In this paper, I present a comparison of the relative efficiency of basking and hoop traps for catching Painted Turtles in 10 central Minnesota lakes over a two-year period.

Basking traps used for this study were modeled after traps used by local commercial turtle harvesters (Fig. 1). Traps consisted of a wood frame, 60 × 60 cm at the base, with a net basket underneath. Strips of styrofoam were attached to the bottom of the wood frame for buoyancy. The net basket, attached to the wood frame, was ca. 90 cm deep, 122 cm in circumference, and had 3.8 cm square mesh (Memphis Net and Twine, Tennessee, USA). The sides of the trap were sloped inward to facilitate entry and prevent escape. A cross board was attached to the top of the trap to provide additional basking area and to increase the probability of turtles entering the trap. Hoop traps, made by Memphis Net and Twine, contained a single opening and were 72 cm in diameter with 3.8 cm square mesh. Canned sardines packed in soybean oil were used as bait.

I trapped *C. picta* in 10 central Minnesota lakes that ranged in size from 6 to 64 ha. Trapping was conducted from 26 June to 31 August 2001 and 13 May to 30 August 2002. Basking traps and hoop traps were set simultaneously on each lake for 1–5 days at a time. Traps were typically checked and emptied every day (N = 95 days, range = 17–48 h/trap set, median = 24 h). Each lake was sampled at least seven times during the study (Table 1). Traps were set where turtles were observed to be most abundant which was near the shoreline, adjacent to cattails and other emergent

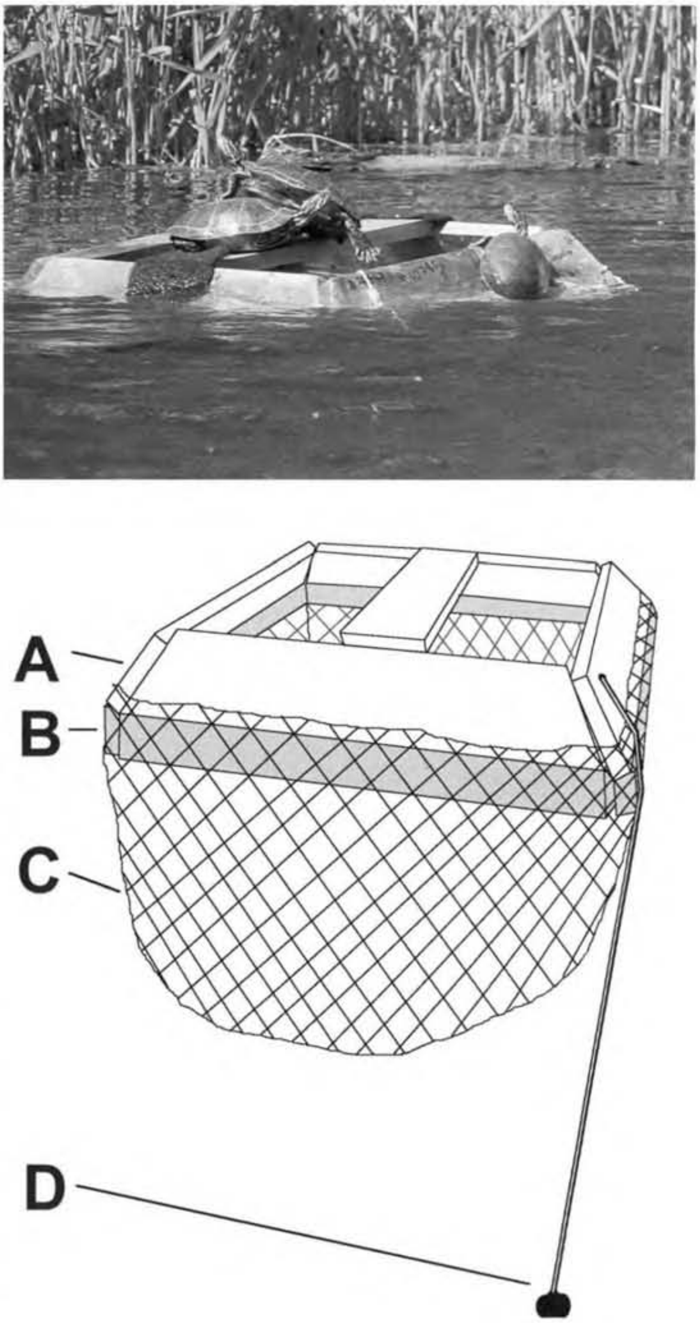

FIG. 1. Top: Painted Turtles (*Chrysemys picta*) on a basking trap in central Minnesota. Bottom: Basking trap design used in this study. A - wood frame; B - foam floats; C - net basket; D - anchor.

TABLE 1. Data summary comparing the mean catch-per-unit-effort (CPUE) of Painted Turtles (*Chrysemys picta*) captured in each lake for hoop and basking traps. Effort is measured in trap-hours. The number of traps is shown as the mean and the minimum and maximum number of traps used to sample each lake.

vegetation, in May and June, and out from shore near floating mats of vegetation in July and August. Traps were also set near sites where *C. picta* were observed basking. Trap efficiency was quantified as catch-per-unit-effort (CPUE) with effort measured as trap-hours, the number of traps on a lake multiplied by the number of hours set. CPUE was calculated for both trap styles for every sample.

I recorded trap style, sex, and straight-line carapace length for every turtle captured. Front claw length and position of the cloaca relative to the rear edge of the carapace was used to classify each turtle as male or female. Juveniles were animals with no discernable secondary sex characteristics and a carapace length less than 10 cm (Ernst and Ernst 1973).

Two statistical analyses were conducted to determine whether catch differences between basking traps and hoop traps were significantly different. The first analysis tested the difference of mean CPUE for basking traps and hoop traps for every sample using a nonparametric Wilcoxon rank sum test for independent groups. A nonparametric test was used because mean CPUE was not normally distributed. The nonparametric analysis compared the relationship between the number of turtles captured and trap style, but it did not take into account the numerous environmental, seasonal, and gender-based factors that are thought to influence trapping success in painted turtles. The second statistical analysis, therefore, included several independent variables in a multiple linear regression model. Effort was analyzed as an independent variable because CPUE data were not normally distributed even after transformation. Independently examining variables that make up a ratio is one way to overcome normality problems (Sokal and Rohlf 1995). Catch data, the number of turtles captured in each sample, were transformed ($\ln[n+1]$) to better fit a normal distribution. Normal quantile plots were inspected *a posteriori* to verify that residuals were normally distributed. The following linear regression model was used to analyze catch data: catch = trap style + lake + month + effort + sex + residual. Trap style was a categorical variable that identified traps as a floating basking trap or submerged hoop trap; lake was a categorical variable that accounted for the numerous individual differences of each lake such as area, productivity, and suitable nesting habitat; month was a categorical variable that accounted for seasonal differences in trappability; effort was measured as trap-hours, the number of traps multiplied by the number of hours they were set; and sex categorized turtles as males, females, and juveniles.

Possible seasonal and gender biases of the two trap types were also explored. I used a series of Chi-square goodness of fit tests to determine if male: female sex ratios differed significantly from 1:1 for each month for both trap types for each lake. The 1:1 sex ratio was chosen as an arbitrary reference point and was not meant to imply a 1:1 sex ratio actually exists in the populations under study. Statistical analyses were conducted using JMP IN Version 4.0.4 (Sall et al. 2001).

I marked 1690 *C. picta* and subsequently recaptured 426 *C. picta* (total captures = 2116). I captured 238 males, 72 females, and 5 juveniles in hoop traps (total = 315) and 1081 males, 464 females, and 256 juveniles in basking traps (total = 1801). Basking traps had a significantly higher CPUE than hoop traps ($\chi^2 = 79.3626$, df = 1, $P < 0.0001$) with a mean CPUE of 0.068 turtles per trap-hour in basking traps compared to 0.029 turtles per trap-hour in hoop

TABLE 2. Significance tests of the multiple linear regression comparing the number of Painted Turtles (*Chrysemys picta*) captured to individual lake effects (lake), seasonal effects (month), effort measured as trap hours (TH), trap style (either basking traps or hoop trap), and sex (male, female, or juvenile).

traps. Basking traps caught more turtles per trap-hour in each age and sex class than hoop traps in most lakes (Table 1). The multiple linear regression analysis found the number of turtles captured was significantly correlated to trap effort, individual lake, turtle gender and age, and trap style, and the number of turtles captured was not correlated with the seasonal variable, month (Table 2).

Both trap types caught more males than females and basking traps caught substantially more juvenile *C. picta* than hoop traps. Male: female sex ratios differed significantly from 1:1 for both trap types consistently in several lakes, particularly Lake Maria (Table 3). Male: female sex ratios also differed from 1:1 in most populations during August. Because not all populations were sampled every month it was not possible to statistically compare seasonal differences in sex ratio across all lakes.

The basking trap design presented in this paper was substantially more efficient than hoop traps for catching *C. picta*, particularly juveniles. Basking traps captured twice as many turtles as hoop traps. The results presented here agree with other comparisons between basking traps and hoop traps in basking turtles (Browne and Hecnar 2005; McKenna 2001). The applicability of these results across the range of *C. picta* is unknown because sampling by either hoop trap or basking trap depends on the behavior of turtles, and geographic variation in behavior is common (Foster and Endler 1999). With this in mind, researchers wanting to maximize the return for their effort, particularly for mark-recapture studies, should consider the use of basking traps for capturing *C. picta*.

Four of the five variables examined in the multiple linear regression contributed to overall trap efficiency. The first variable was effort. Simply increasing the amount of time or the number of traps used increased the number of turtles captured. The second variable contributing to trap efficiency was differences between lakes. Environmental factors such as lake size, productivity, the availability of nesting areas, and proximity to roads can influence

the relative abundance of turtles in the sampled population which should be related to hoop trap and basking trap efficiency (Cagle and Cheney 1950; Seber 1982). Operating under the assumption that the number of turtles caught was proportional to the effort used to catch them (Seber 1982), traps should be more efficient in lakes with abundant turtle populations. Bury (1979) and Zweifel (1989) noted large differences in population density between different *C. picta* populations with some populations having an order of magnitude more turtles per unit area than other populations. The CPUE of both hoop traps and basking traps differed significantly between lakes and was consistent with expected variation related to differences in the relative abundance of *C. picta* in different populations.

The third variable contributing to trap efficiency was sex. Significantly more males than females were captured in both trap types. The high capture rates of males implied: 1) the populations were male biased; 2) both trap types were male biased; or 3) a combination of a male biased population and trap bias. The consistent male capture bias in Lake Maria for both trap styles in every month suggests an actual male bias in that population. Several authors have suggested that hoop traps were male biased because of the attraction of males to captured females (Cagle and Cheney 1950; Frazer et al. 1990; Ream and Ream 1966, Vogt 1979). Because the ratio of males: females was roughly the same between trap styles basking traps were no more or less biased toward capturing males than hoop traps. Basking traps captured a larger proportion of juveniles than hoop traps suggesting that juveniles were either not as attracted to the bait as adults or that juveniles could more easily escape from hoop traps. It is also possible that juveniles were over-represented in basking traps. Because of their size, juveniles gain and lose heat more quickly than adult turtles (Lefevre and Brooks 1995) and may need to bask more frequently, resulting in more frequent captures in basking traps.

The fourth variable contributing to trap efficiency was the trap style. I observed both *C. picta* and *Chelydra serpentina* escaping from set hoop traps during this study, an occurrence also reported by Frazer et al. (1990). The decreased efficiency of hoop traps may have been related to the inability to retain captured turtles and not to differences in the attraction to the traps although these factors could not be separated here.

Hoop trap and basking trap efficiency are affected by the trap's ability to attract turtles (Novak 1987). Turtles can be attracted to traps for several reasons such as the need to bask on basking traps (Plummer 1979) and the bait in hoop traps (Cagle and Cheney 1950). My results may have been influenced by the choice of bait used, as some baits may be more effective at attracting *C. picta* than others (Jensen 1998), although Ernst (1965) found canned sardines, the bait used in this study, to be the most effective for trapping painted turtles. Male turtles may also be attracted to traps containing females and trap efficiency should increase for male turtles during periods of mate-searching activity (Cagle and Cheney 1950; Frazer et al. 1990; Thomas et al. 1999, Vogt 1979). The increased male capture bias during August was likely a result of mate searching behavior as copulation in *C. picta* most often occurs in the fall (Gist et al. 1990).

The ability to detect differences in basking trap efficiency, based on the seasonal and reproductive energy requirements of *C. picta*, was not confirmed here. Basking trap efficiency should increase as the need to bask increases. The primary purpose of basking is thermoregulation (Boyer 1965) and turtles bask more or less based on seasonal and reproductive energy requirements (Krawchuk and Brooks 1998; Lefevre and Brooks 1995; Ream and Ream 1966; Thomas et al. 1999). Egg development and nesting in females and mate-searching and spermatogenesis in males are energetically demanding and correlated with increased basking (Krawchuk and Brooks 1998; Thomas et al. 1999). Detecting differences in male basking behavior due to differing energy requirements was confounded by the possibility of male turtles being attracted to females already in the traps. Furthermore, monthly differences in the CPUE of male turtles were observed in both trap types and could have been related to mate-searching behavior. Additional work with a different experimental design would be needed to tease apart the influence of these behaviors on trap efficiency.

Acknowledgments.—Funding for this project was provided by Minnesota Department of Natural Resources, Division of Ecological Services, Natural Heritage and Nongame Research Program in a grant to A. Simons and the Bell Museum of Natural History. Minnesota State Parks, Three Rivers Park District, and St. John's University and Abbey provided access to lakes. L. Class, J. Egge, T. Faust, C. Phillips, K. Yuvaraj, and C. Zwamanda helped in the field. B. Mies and D. Rodahl provided descriptions and pictures of commercial traps. J. Lang, J. Moriarty, P. Berendzen, and A. Simons provided helpful comments on an earlier version this manuscript. K. Yuvaraj and L. Class helped build and repair traps. All trapping was conducted under Minnesota DNR special permits 10457 and 10785 and Minnesota State Parks permits 2001-35 and 2002-12. Animal use follows University of Minnesota animal care protocol No. 0105A99921.

Amphibian species and populations are declining all over the world (Houlahan et al. 2000; Stuart et al. 2004). Hence, conservation of biodiversity is a globally crucial topic. Genetic characters are essential in order to promote conservation of biodiversity, because they contain much information about populations and species, such as intrinsic variability, population structure, historical patterns of gene flow, and phylogenetic relationships (Avise 2000). By using such information, we can define conservation units for each animal, and monitor genetic diversity.

As a genetic method, protein electrophoresis has been widely used in animals. This method requires fresh materials such as blood or other tissues (e.g., muscle, liver). DNA methods also have become popular since the polymerase chain reaction (PCR) was introduced in the late 1980s (Mullis and Faloona 1987; Saiki et al. 1985). PCR-based genotyping methods have highly progressed, and enable us to use a variety of materials including a small number of cells. These materials include hair, feces, urine, and buccal cells in mammals, feathers and eggshells in birds, and scales and fins in fishes (reviewed by Morin and Woodruff 1996).

In amphibians, both protein and DNA analyses have generally used materials obtained by sacrificing individuals. Therefore, sampling might have a serious impact on declining populations and species. Consequently, it is essential to establish sampling methods that avoid irreversible damage or viability reduction. Conservation genetic surveys should not contribute to the problem they seek to alleviate.

There are several studies that describe sampling methods without physical damage (Davis et al. 2002; Pidancier et al. 2003). Davis et al. (2002) used epidermis as DNA source material. Pidancier et al. (2003) used oral mucosa. In addition to these two materials, we employed molted skin and feces, and investigated four points: 1) collecting cells from oral mucosa, epidermis, molted skin, and fecal samples; 2) extracting DNA from each sample; 3) risk of contamination; 4) practicality of these methods. Materials were collected from Urodela and Anura in previous studies and Gymnophiona in the present study to include three orders of amphibians.

METHODS

Sampling.—Four families (Typhlonectidae, Hynobiidae, Salamandridae, and Rhacophoridae) belonging to three orders of amphibians were tested. Samples were collected from one individual each of the Cayenne Caecilian (*Typhlonectes compressicauda*), the Hokkaido (Yezo) Salamander (*Hynobius retardatus*) and the Japanese Fire-bellied Newt (*Cynops pyrrhogaster*), and three individuals of the Forest GreenTreefrog (*Rhacophorus arboreus*). The oral mucosa (buccal cells), and epidermis and molted skin (epidermal cells) in Gymnophiona and Caudata, and the oral mucosa (buccal cells), epidermis (epidermal cells), and feces (intestinal cells) in Anura were used as genetic source material. Each surface of mouth cavity, skin, and feces was scrubbed off with sterilized cotton swabs. In order to open the mouth for collecting buccal cells, we used a sterilized toothpick. Each sample was shaken off a cotton swab in 1.5 ml tubes filled with 0.6 ml of TNE buffer (10 mM Tris-HCl [pH 7.5], 100 mM NaCl, 1 mM EDTA-2Na [pH 8.0]). A section of molted skin cut with sterilized scissors was thoroughly washed with TNE buffer, and soaked in 1.5 ml tubes filled with 0.6 ml of TNE buffer. To confirm whether or not the DNA sequences obtained from each sample actually represented the target ones, a liver sample of the tested individual, removed in fully anesthetized condition with acetone chloroform, was sequenced.

Cell staining.—We ascertained the existence of cells scrubbed off from each animal by placing the cotton swab on a glass slide, dried in air, and fixed with May-Grunwald stain solution. They were washed with water, stained with Giemsa solution, and washed again with water. After drying, they were examined with a microscope.

Genotyping.—All samples preserved in TNE buffer were treated with 30 µl of 10% sodium dodecyl sulfate (pH 7.2), and digested with proteinase K (final concentration: 0.5 mg/ml) at 37°C for 15 hours. Proteins were removed with a standard phenol chloroform extraction, followed by ethanol precipitation (Sambrook et al. 1989), and DNA was resuspended in 100 µl of TE buffer (10 mM Tris-HCl [pH 7.5], 1 mM EDTA-2Na [pH 8.0]). The concentration of DNA in all extracts was measured using spectrophotometer.

PCRs were performed on a TaKaRa PCR Thermal Cycler 480, with 3 µl of DNA solution and 0.9 units of Expand High Fidelity PCR System enzyme mix (Roche Diagnostics GmbH) in the total 21.8 µl of a reaction mixture contained 2.5 µl of 10X Expand HF buffer with 15 mM $MgCl_2$ (Roche Diagnostics GmbH), 4 mM dNTPs, 25 pmoles of a mixture of a forward and reverse primer, 1

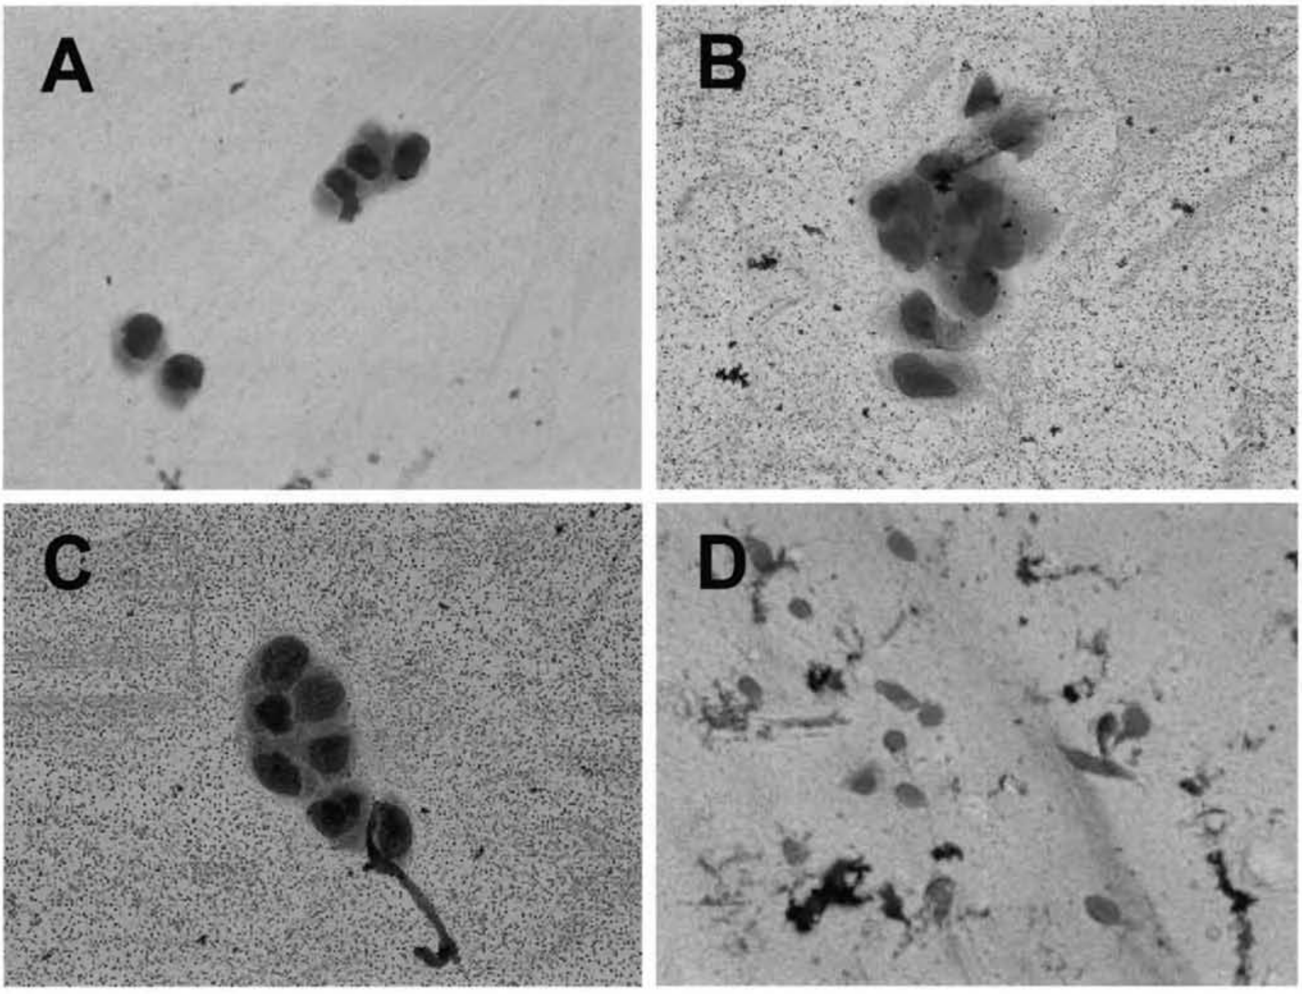

FIG. 1. Buccal cells stained by May-Grunwald Giemsa method: A) Cayenne Caecilian (*Typhlonectes compressicauda*); B) Hokkaido (Yezo) Salamander (*Hynobius retardatus*); C) Japanese Fire-bellied Newt (*Cynops pyrrhogaster*); D) Forest Green Treefrog (*Rhacophorus arboreus*). These cells were observed in all samples.

TABLE 1. Results of PCR in all samples: A) Cayenne Caecilian (*Typhlonectes compressicauda*); B) Hokkaido (Yezo) Salamander (*Hynobius retardatus*); C) Japanese Fire-bellied Newt (*Cynops pyrrhogaster*); D) Forest Green Treefrog (*Rhacophorus arboreus*). A successful PCR is indicated by "yes" and failure by "no." In a case of DNA from molted skin of the *C. pyrrhogaster*, PCRs succeeded by dilution of the quatity of DNA into one third (from 3 µl to 1 µl).

µl of dimethylsulfoxide (DMSO). The primers used were L2606 (5'-CTGACCGTGCAAAGGTAGCGTAATCACT-3') and H3056 (5'-CTCCGGTCTGAACTCAGATCACGTAGG-3')(Hedges et al. 1993) for the 16S rRNA gene of mitochondrial DNA (mtDNA) for Gymnophiona and Urodela, and L14850 (5'-TATCTTCATTATGAAACTTTGGGTC-3') and H15548 (5'-AACAGAAAATATCATTCTGGCTTAAT-3') newly designed for mtDNA cytochrome *b* gene in Anura. The numbering system followed the human sequence (Anderson et al. 1981). A template-free sample was used as a negative control. The PCR profiles consisted of 10 min denaturation at 94°C, and then 35 cycles of 1 min denaturation at 94°C, 2 min annealing at 45°C, and 3 min extension at 72°C, and a final hold of 5 min extension at 72°C. The specific DNA fragments were separated by electrophoresis using 3% NuSieve GTG (BioWhittaker Molecular Applications) agarose gel. A gel containing specific DNA fragments was cut out. Double stranded DNA products for sequencing were purified from the gel by using EASYTRAP™ Ver.2 (TaKaRa).

Thermo Sequenase Cycle Sequencing Kit (USB Corporation) was used for sequencing reaction. Sequencing products were separated on a 5.5% Long Ranger (BioWhittaker Molecular Applications) gel by using a LI-COR 4200S-1 DNA sequencer, and their sequences were subsequently optimized by eye. Sequences were aligned and compared with GENETYX-WIN (ver.4, Software Development Co., Ltd. 1999).

RESULTS

The presence of cells in oral mucosa, epidermis, molted skin, and feces specimens was assessed by cell staining method. Buccal cells could always be observed sufficiently in all samples (Fig. 1), while numbers of cells from epidermis and feces were small.

The concentration of DNA in the molted skin samples from *Typhlonectes compressicauda* and *Cynops pyrrhogaster* showed 0.24 µg/µl and 0.12 µg/µl, respectively, but the others could not be measured. That is, they were under detectable limits. The presence of DNA extracted from each sample was ascertained by PCR. Firstly, PCR product was observed in all samples except a case of molted skin of the *C. pyrrhogaster* (Table 1). The DNA solution extracted from molted skin of the *C. pyrrhogaster* showed brown color instead of usually colorless DNA solutions. In this case, PCR product was observed by dilution of the quantity of DNA into one third: from 3 µl to 1 µl. On the other hand, DNA extracted from buccal cells of *Rhacophorus arboreus* was amplified in large quantities. The amplification was achieved even in a case where the quantity of DNA was diluted into 1/100 (Fig. 2). Finally, PCR products could be obtained from all samples except the negative controls.

All nucleotides between forward and reverse primers were sequenced in all samples. Base sequences were 431 base pairs (bp), 465bp, 454 bp of the 16S rRNA gene in *Typhlonectes compressicauda*, *Hynobius retardatus*, and *Cynops pyrrhogaster*, respectively, and 697 bp for the cytochrome *b* gene in *Rhacophorus arboreus*. Base sequence of different isolates from the same individual were consistent and identical to the sequence of DNA extracted from liver. No evidence of contamination among isolates was detected.

DISCUSSION

The previous genetic surveys in amphibians have employed protein analyses that have usually used materials like blood and tissues. Similarly, mitochondrial DNA analyses have used muscle and liver, even when coupled with PCR methods, and a few researchers used eggs and embryos (e.g., Yang et al. 1994). All of these methods require lethal sampling. Previous non-lethal sampling methods include tail-tip tissues in live newts (Arntzen and Wallis 1991), toe-tip tissues in live frogs (Gonser and Collura 1996), and tadpole tails (Zeisset et al. 2000).

Toe-clipping was introduced more than a half century ago (Bogert 1947), and has been commonly used to identify individu-

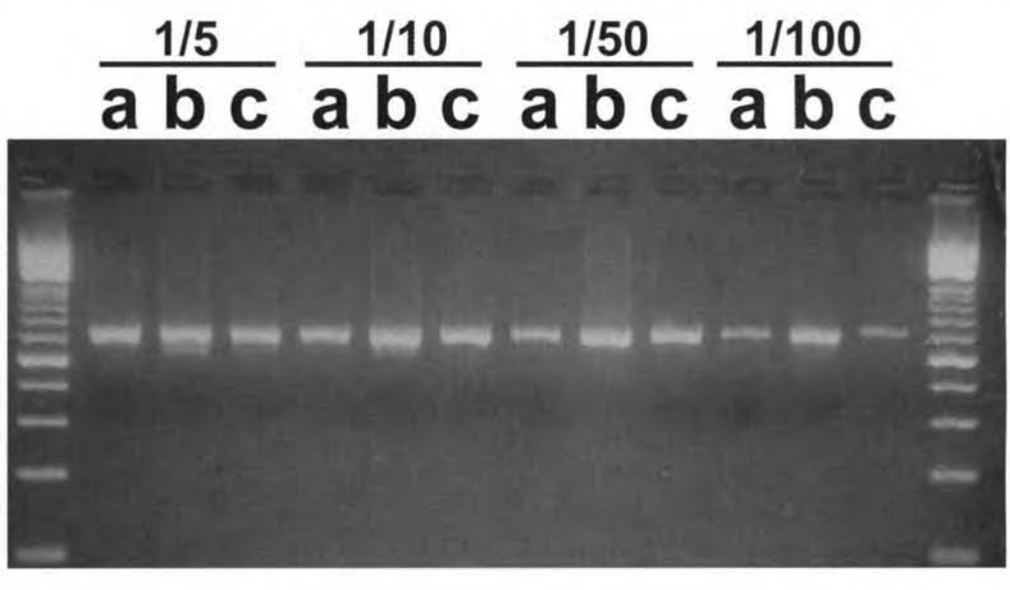

FIG. 2. Electrophenogram of PCRs using DNA extracted from buccal cells of three Forest Green Treefrogs (*Rhacophorus arboreus*). Small letters (a–c) denote individual frog samples. From left to right, dilutions of DNA were 1/5, 1/10, 1/50, and 1/100. The amplification was clearly confirmed even at 1/100.

als in the field (Donnelly et al. 1994). This is very convenient for individual recognition, and clipped toe-tip is available for age determination (e.g., Francillon-Vieillot et al. 1990) as well as genetic analysis. However, negative effects on survival have been shown in Anura (e.g., Clarke 1972; Golay and Durrer 1994). Further, Arntzen et al. (1999) demonstrated that the tail-clipping—as generally used for marking and to obtain material for molecular analyses in Caudata—affected growth in *Triturus cristatus*, although not survival. Recently, McCarthy and Parris (2004) indicated that the estimated decline in return rate of 4–11% for each toe clipped assumed that the adverse effects are independent of the total number of toes clipped. For these several reasons, amphibian biologists should use noninvasive methods to collect DNA resources.

In the present study, we tried several sampling methods that would minimize impacts to individuals. We collected the oral mucosa (buccal cells), epidermis and molted skin (epidermal cells), and feces (intestinal cells) from four families (Typhlonectidae, Hynobiidae, Salamandridae, and Rhacophoridae) representing three orders of amphibians. Many buccal cells were obtained especially from *Rhacophorus arboreus*. Theoretically, more than 3,000 PCRs are possible in this case. The body size (snout–vent length; SVL) of this frog is relatively large, 57 mm SVL on average in males and 72 mm SVL on average in females (Maeda and Matsui 1999). Hence, surface area sampled with a cotton swab was wide. Therefore, it is suggested that buccal cells can be obtained effectively from animals with a large body size and large mouth cavity. Although there is a difference in efficiency among species, these methods must be able to be widely applied to amphibians.

Epidermal sampling seems most convenient as Davis et al. (2002) reported. But as a practical matter, this method requires caution to prevent contamination by researcher because we catch animals by hand. It may be difficult to find either molted skin or feces except in captivity. Additionally, in cases where amphibians eat other amphibians, there is a possibility that the feces contain DNA from both. However, most of the cells ingested by animals are digested and destroyed. DNA in the cell is fragmented by deoxyribonuclease. That is, in feces, DNA from other amphibians has already been fragmented. On the other hand, cells on the "surface" of feces have been in quite recent contact with the intestinal wall, so that they contain DNA in better condition for PCR. In the field, these three sampling methods may not be practical in all cases. Buccal cells have few risks of contamination because researchers seldom directly touch the mouth cavity. However, when buccal cells are collected without anesthetizing the animal, it may be necessary to provide additional restraint to minimize risk of injury to the animal. Notably, we were able to collect buccal cells easily from *Salamandrella keyserlingii* anesthetized by MS-222 (Tanaka-Ueno, pers. obs.). Where the appropriate training is available, it may be better to anesthetize specimens in order to make sampling easy and improve animal welfare. Considering the quantity of DNA included in each sample, the risk of contamination, and practicability in the field, the best sampling method may be swabbing buccal cells from oral mucosa.

Buccal cell collection can minimize physical impact to animals and may enable us to acquire genetic information without reducing survivorship of endangered species. This noninvasive sampling method is convenient and reliable, and is therefore well suited not only for sensitive species but also animal welfare in general.

Acknowledgments.—We thank Dr. Shunji Goto for technical support of cell staining method and Seiji Ikeda for assistance of laboratory work. The project was supported by Research Fellowships of the Japan Society for the Promotion of Science for Young Scientists (No. 5397) to TT-U.

A Device for Excluding Predators from Pitfall Traps

ADAM W. FERGUSON
and
MICHAEL R.J. FORSTNER

e-mail: adamwferguson@gmail.com

Pitfall trapping is a common technique for sampling small vertebrates (Jenkins et al. 2003; Sutton et al. 1999). As with most live trapping methods, trapped animals might incur mortality through desiccation (Jenkins et al. 2003), drowning (Aubry and Stringer 2000), starvation (Yunger et al. 1992), exposure (Padget-Flohr and Jennings 2001), and increased predation risks (Dodd and Scott 1994). However, most studies rarely mention predation and typically only attempt to mitigate the other problems. Only anecdotal evidence of predation is mentioned and mainly deals with predation within the pitfalls (Jenkins et al. 2003) or disturbances to pitfall covers (Sutton et al. 1999). We present a device to reduce predation of animals captured in pitfall traps. Our design provides an alternative to cover boards that are often employed in drift fence studies as anti-predatory mechanisms (Phillips et al. 2002) and is unique in its ability to capture a wide array of small vertebrates, including frogs and toads, while providing secure protection from larger vertebrate predators. We devised predatory exclusion devices (PEDs) in response to increased predator activity (scat, tracks, and disturbance) observed along specific drift fence arrays. Our ultimate goal was to design an inexpensive and time-efficient exclusion device that would reduce predation risks to captured animals in pitfall traps without jeopardizing capture rates of target species.

We operated eighteen terrestrial drift fences year-round and checked them daily at the Griffith League Ranch in north-central Texas, Bastrop County. Our study was part of a long-term study of the endangered Houston Toad (*Bufo houstonensis*). Arrays were either linear or Y-shaped (Bury and Corn 1987) and erected using aluminum flashing (Gibbons and Semlitsch 1981) with 39 19-L buckets distributed among the fences. Only pitfall traps known to have captured adult Houston Toads during previous survey periods were outfitted with PEDs. Eleven of 18 arrays captured *B. houstonensis* among 34 pitfalls. We outfitted 32 PEDs to the terminal pitfalls of the 11 arrays.

PEDs had a cover-board, two strips, four posts, cable ties, and binder clips. We built 40.64 × 40.64 × 1.27 cm cover boards from treated plywood. Each board had four 5.0 cm holes drilled 1.27 cm from each corner and a 30.48 × 1.27 cm gap center cut so the cover board seated at the fence's end. Strips measured 7.62 × 40.64 × 1.27 cm and had two 1.27 cm holes drilled at each end at 1.27 cm from the end. We cut re-bar (1.27 cm) into 60.96 cm lengths for the posts (Fig. 1). For assembly, we first drove the posts 40.64 cm into the ground and oriented the strips parallel to the fence at 10.16 cm high. Second, we cinched cable ties on the posts above and below the strips then placed the cover board snugly on top of the strips. Lastly, we secured the cover board to the strips with two large binder clips. Our design enabled animals to crawl or

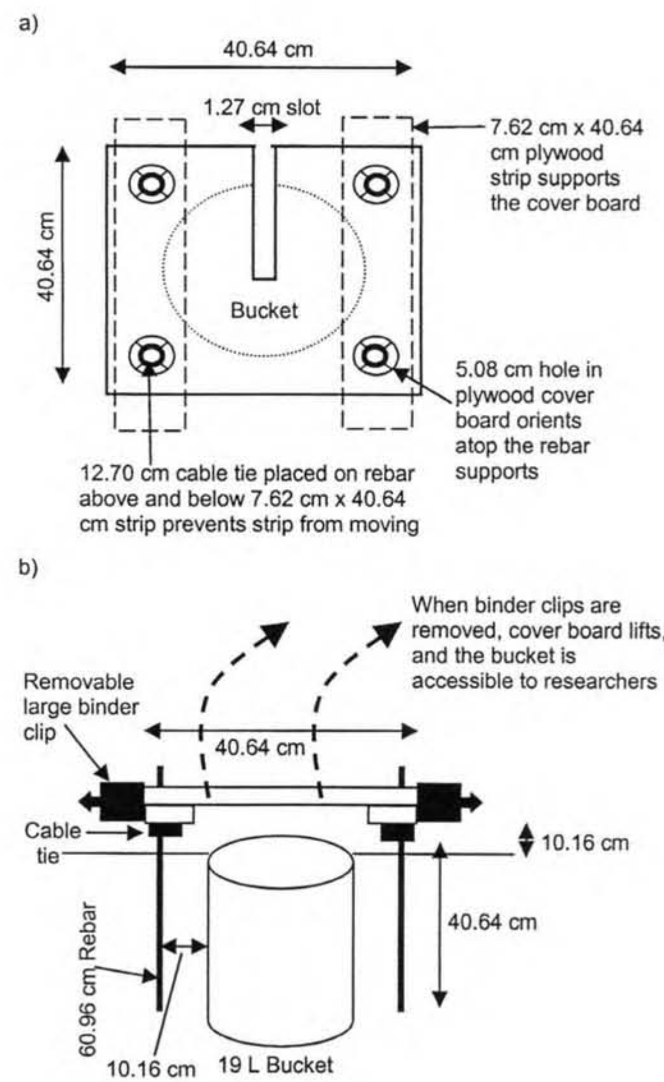

FIG. 1. Detailed drawing of a Predator Exclusion Device illustrating its general operation and an aerial view (a) plus a lateral view (b) of the PED with pitfall trap.

hop underneath the PED thus preventing larger vertebrate predators from reaching the pitfalls' bottom.

Creating a PED secure enough to deter predators yet still readily removed by the researchers was an important goal. With such a large trapping regime, checking each trap, especially on wet spring days with dozens of captures, might take anywhere from a few minutes to several hours. We estimated removal of PEDs added approximately one minute to check each pitfall. Beyond the labor, drift fences can be expensive creating problems in short-term studies with smaller budgets (Malone and Laurencio 2004). We estimated the costs for wood, cable ties, re-bar, and binder clips at approximately US \$5.00 per PED. An added benefit is preventing injury to unaware livestock and personnel, a concern when conducting studies on sites with high activity.

During an eight-month test, all PEDs remained intact with no damage or disturbance. Most importantly, the presence of PEDs did not affect the capture of the target species, the endangered Houston Toad. The proportion of *B. houstonensis* caught in unprotected pitfalls out of total captures from 2003 did not significantly differ from the proportion of *B. houstonensis* caught in PED protected pitfalls during the 2004 season (95% CI P_1-P_2 = -0.0947 < P_1-P_2 < 0.1227) indicating that capture success was not affected by the presence of the PEDs. The same pattern was observed in captures of the Southern Leopard Frog *Rana sphenocephala*, whose proportional captures in protected and unprotected pitfall traps did not significantly differ among the 2003 and 2004 seasons (95% CI P_1-P_2 = -0.0145 < P_1-P_2 < 0.1325). However, a majority of these frogs were juveniles, large adult ranids may be excluded from PED protected pitfalls due to the height limitation of the device.

Three months into the study we documented failed predation attempts at ten pitfalls having PEDs using ten Deercam® motion sensor cameras. Cameras recorded predators entering pitfalls without PEDs and attempting, but failing to enter pitfalls with PEDs (specifically *Procyon lotor*). Despite the PEDs' effectiveness, agile predators (e.g., snakes) can still enter pitfalls and consume animals. Our PEDs provide an inexpensive solution to predation from larger vertebrates. Although alternatives to pitfall trapping that also help limit predation in herpetofaunal studies exist, these techniques are often limited in taxon sampling and even increase other mortality factors such as desiccation (Jenkins et al. 2003; Lohoefener and Wolfe 1984). We think our technique provides an inexpensive and unbiased tool that will aid in reducing predation associated with pitfall trapping for other studies.

Acknowledgments.—We thank Francis L. Rose for comments on an earlier draft. We adhered to all rules and regulations outlined by the Society for the Study of Amphibians and Reptiles and regulatory agencies during this research. We conducted research under Federal Permit # TE039544-1, State Permit # SPR-0102-191, and Texas State University IACUC Permit # 5QRS45-02.

An Improved Blood Sampling Technique for Hatchling Emydid Turtles

GRÉGORY BULTÉ

Blood sampling is useful for the study of behavior, ecology, and physiology. It is a minimally invasive method of obtaining tissue that allows, for example, genetic, toxicological, and stable isotope analyses. Various techniques for obtaining blood from turtles have been described (Avery and Vitt 1984; Bennett 1986; Owens and Ruiz 1980; Rogers and Booth 2004; Wibbels et al. 1998; reviewed by Kutchling 1999). Most published techniques apply to adult turtles, with the exception of Bennett (1986) and Wibbels et al. (1998) who described blood sampling from the dorsal cervical sinus and the subcarapacial vein of hatchling sea turtles. We are unaware of a blood-sampling technique for hatchling emydid turtles, which are smaller (usually < 10 g) than cheloniid hatchlings (≈ 20 g). Although we found the technique reported by Wibbels et al. (1998) to be useful on smaller emydid hatchlings, we successfully used an alternative technique that we believe is more appropriate and less detrimental. Here we describe this technique, report our success, and discuss its advantages over the previously described techniques.

In summer 2005, we collected 34 gravid female Common Map Turtles (*Graptemys geographica*) at a nesting site in Lake Opinicon (100 km S of Ottawa, Ontario) and induced oviposition with oxytocin (10 IU/kg) (Ewert and Legler 1978). We incubated eggs in the laboratory at 29°C and we obtained blood on all hatchlings (N = 338) to determine paternity. Hatchlings weighed 4.7–10.3 g (mean = 7.5, S.D. = 1.1 g). We collected between 0.03 and 0.05 ml of blood with a 0.5 ml insulin syringe (B-D U-100) fitted with a 13 mm long (28.5 ga) needle. We obtained blood from the coccygeal vein, which runs along the dorsal midline of the tail (Fig. 1). The venipuncture site was between the cloaca and the base of the tail, along the dorsal midline (common map turtles have a yellow stripe running along that midline). The needle was directed cranioventrally at a 45° angle and inserted approximately 2 mm deep between two adjacent vertebrae. If the needle went deeper than 2 mm, it meant that the needle was beside the vertebrae and no blood could be obtained. As soon as the opening of the needle was in the skin, the plunger of the syringe was withdrawn gently (up to the 0.2 ml mark) to create a vacuum. Care was taken not to apply excessive negative pressure to prevent collapse of the vein (Rogers and Booth 2004). If blood did not appear in the syringe immediately, we slowly rotated the syringe and/or gently increased or decreased the angle until blood was withdrawn into the syringe. If an insufficient amount of blood was obtained on the first try, we made a second attempt a few mm closer to the base of the tail. If no blood was obtained on the second attempt, however, we sampled the subcarapacial vein (a branch of the external jugular according to Rogers and Booth (2004)) as described by Wibbels et al. (1998) to avoid damaging the tail blood vessels. For 248 of the 338 samples taken, we recorded the presence of extracellular fluid, the number of attempts (up to two), and the volume of blood taken in each attempt.

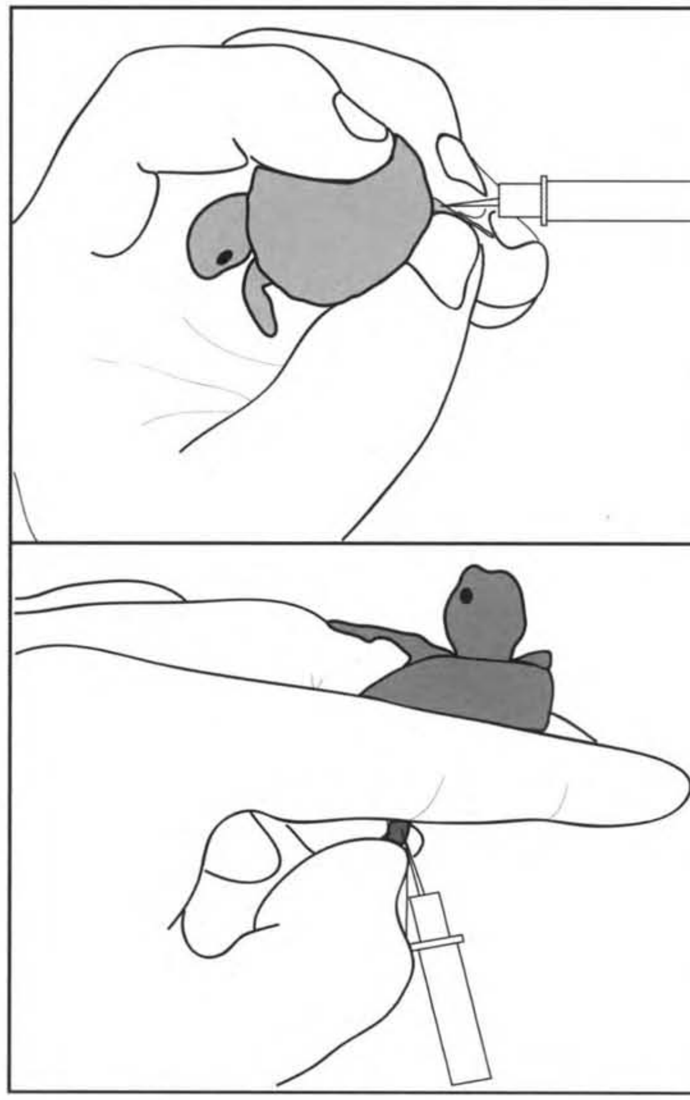

Fig. 1. Two ways of handling hatchling turtles for sampling blood from the coccygeal vein.

In a maximum of two attempts, we were successful in taking at least 0.03 ml (mean = 0.047 ml) of blood from the coccygeal vein for 83% of the hatchlings. For the remaining 17% of the hatchlings, we obtained the blood from the subcarapacial vein (also in a maximum of two attempts). Our success at obtaining blood from the coccygeal vein was independent of hatchling size (logistic regression with carapace length as the independent variable: $\chi^2 = 0.0012$, $P = 0.97$). This result suggests that the technique is practicable on hatchlings of smaller species, such as Painted Turtles (*Chrysemys picta*) or Spotted Turtles (*Clemmys guttata*) that overlap in size with the smaller hatchlings of Common Map Turtle (Ernst 1994). However, this technique may be difficult to apply on species with relatively short tails.

We noted the presence of extracellular fluid or lymph in 16% of the samples from the coccygeal vein, but in 75% of those samples

it was estimated to be ≤ 0.01 ml. In the samples from the subcarapacial vein, extracellular fluid or lymph was noted in 58% of the samples and exceeded 0.01 ml in 86% of those samples. Extracellular fluid and lymph are undesirable in blood samples for both genetic analysis and haematological studies (Lopez-Olvera et al. 2003). We released most turtles 1–3 weeks after blood sampling and none died or showed signs of weakness while in captivity. Another 120 hatchlings were kept in the laboratory for more than a month and none died.

We believe that the coccygeal vein should be preferred over the subcarapacial vein for venipuncture in hatchlings for three reasons. First, bleeding never occurred when we sampled from the coccygeal vein, whereas occasional bleeding occurred when we took blood from the subcarapacial vein. The subcarapacial vein is more likely to produce abundant bleeding because it is a larger vessel. Second, we obtained extracellular fluid more often and in greater amounts when we used the subcarapacial vein. Finally, vital organs are less likely to be injured when blood is taken from the dorsal side of the tail rather than from the head and neck regions.

Acknowledgments.—The animal care committee of the University of Ottawa approved the protocol (BL-179) for this study. For their able help, we are grateful to E. Ben-Ezra, M.-A. Gravel, C. K. McNab (Kawartha Turtle Trauma Center), and F. Phelan. Logistical support was provided by the staff of the Queen's University Biological Station. We also thank two anonymous reviewers for providing valuable comments on an earlier version of the manuscript. Funding was provided by the University of Ottawa, a Discovery Grant from the Natural Sciences and Engineering Research Council of Canada to GBD, Parks Canada, and a graduate scholarship from the Fonds Québécois de Recherche sur la Nature et les Technologies to GB.

Many ecological studies of amphibians and reptiles commonly use toe clipping to permanently mark small species. However, researchers have noted deleterious effects on locomotion and even survival caused by toe clipping (Bloch and Irschick 2004; Clarke 1972; Dodd 1993). Alternatives to toe clipping include implantable and surface-marking techniques, yet the former requires the species of interest to have transparent or semi-transparent skin, and the latter may be highly susceptible to wear or loss by shedding.

The Mediterranean House Gecko (*Hemidactylus turcicus*) is an introduced species that is found in association with human habitation in many regions of the United States (Selcer 1986), including Tucson, Arizona where we conducted our study. In our experience, simple surface-marking techniques (permanent marker, correction fluid, etc.) are inadequate for monitoring individual *H. turcicus* because these lizards shed frequently. Our goal was to provide a permanent marking technique for individual *H. turcicus* for periods in excess of 2 wk to facilitate population monitoring.

Based on our observations, the variation in dorsal patterns is not readily distinguishable among individual *H. turcicus*. For small species like *H. turcicus* (SVL = 44–59 mm; body mass = 2.1 g), external tags are often not appropriate. However, internal microtagging has been used successfully in a number of studies (e.g., Buckley et al. 1994 for fish). Here, we use implantable elastomer tags (Northwest Marine Technology: Shaw Island, Washington) to mark small geckos. This method uses a two-part silicone-based material mixed immediately before use, which is injected subcutaneously. Injected as a liquid, it soon cures into a pliable, biocompatible solid that remains visible under translucent skin. In *H. turcicus* the best tagging area was the ventral skin surrounding the leg joints because the dorsal surface has a darker, leopard-like pattern. Tag visibility can be enhanced by fluorescing the marker with a blue-light LED or UV light. A single color kit, including the injector, a 5-cc tube of elastomer, mixing supplies, blue LED flashlight with amber glasses, carrying case, and instructions costs U.S. $215, although more complicated kits cost significantly more. These implantable microtags have been used in ecological studies of crustaceans (e.g., Godin et al. 1995), fish (e.g., Goldsmith et al. 2003), amphibians (e.g., Pfennig and Murphy 2000), and reptiles (e.g., Losos et al. 2004).

Capture Methods.—Our preferred method involved a clear "cup" (we used half of a clear plastic water bottle, approximately 8-cm diam) and a thin, hand-sized manila card. The geckos were found mostly in small groups (usually three or four) surrounding the illuminated radii of porch lights of houses. Individuals were wary, and would dash for recesses and holes very quickly if startled. Using the plastic container, it was possible to slowly enclose geckos without immediately startling them. We then slid the card underneath the cup along the wall and the gecko was captured. Spotting individuals proved difficult without using additional light; however, a flashlight usually startled them. Using a dimmer flashlight or simply reflecting the porch light with the manila card provided sufficient light and did not startle the geckos.

Shedding Observations.—We kept 16 geckos in a glass terrarium ($60 \times 30 \times 40$ cm). Geckos were provided with simulated porch light in the form of a 100-W overhead incandescent bulb, which provided both heat and a nighttime light source. Geckos were exposed to sunlight through the windows of the lab during the day. Inside their terraria, geckos were provided with a refugium (egg crate cardboard). *Hemidactylus turcicus* live in groups under similar conditions (e.g., porch lights) on houses and apartment buildings (Davis 1974; Selcer 1986). Each day we fed the geckos small crickets (*Acheta domesticus*) and mealworms (larval *Tenebrio molitor*) and misted them with water. During a 2-wk observation period, five of the 16 geckos shed including one individual that was observed abrading its loose layer of skin against a rough surface. These observations reinforced our impression that shedding would limit the utility of simple surface-marking methods in the field.

Retention Rates of Various Marking Methods.—After the initial 2 wk of observation, each gecko was assigned to one of six groups. Two terraria ($60 \times 30 \times 40$ cm) were placed end-to-end lengthwise with two walls (5-mm foam board held in place with silicon) that divided each tank into three cells. Each cell contained a refugium (made of the same foam board) on one wall, accessible by small holes that provided shelter and darkness (as well as abrasion for shedding). The floor of each terrarium was covered in aquarium rock and artificial plants, which provided cover for ground foraging and another surface to aid in shedding. Two 100-W incandescent lamps were suspended just above the terraria to provide an evenly distributed light and heat source (close enough to simulate porch lights, but with shade provided by refugia). Seven more recently captured geckos were randomly assigned to the four treatments with the original 16 geckos. Thus, we had a total of 23 individuals, four placed in each of five compartments and three individuals in the last compartment (similar to the group sizes observed at porch lights in the field). Without marking any of them, we fed the geckos and allowed them to acclimate to the experimental conditions for 2 d.

We marked individual *H. turcicus* using one of three methods. The first method involved placing a raised cyanoacrylate superglue dot (SGD) on the back, measuring ca. 0.5 cm diam. The second method involved gluing an elastomer alphanumeric tag (ANT: Northwest Marine Technology's VI Alpha Tags, adhered with the same superglue) on the back to create a more visible external marking for comparison with SGD. The third method involved injecting a visible implant elastomer (VIE) into a leg. Geckos were held by hand and the hind leg was extended so the VIE could be injected into the ventral knee joint with a 1-ml syringe.

TABLE 1. Calendar of shedding for 12 *Hemidactylus turcicus* with two surface-marking methods (SGD = superglue dot and ANT = alphanumeric tag). Geckos were marked on day 0. Numbers are the cumulative number of animals that had completely shed and lost their surface mark. Numbers in brackets are the number of individuals that escaped or died.

Marking Treatment	Day 3	4	5	7	8	10	13	15
SGD	0	0	1	2	3	3	5 [1]	5 [1]
ANT	0	1	1	2	2	3	5	5

Geckos were distributed into the enclosures such that there was an individual marked by each method in each of the six cells. In all but the last compartment (which contained only three geckos), one gecko was left unmarked as a control. The experiment commenced with 23 geckos: six individuals marked with SGDs, six with ANTs, six with VIEs, and five unmarked controls. By feeding the geckos ad libitum, providing them adequate light and heat, and misting them with water, they were expected to achieve high levels of activity, thus providing a vigorous test of each marking method for 2 wk.

By day 15, all but one SGD gecko had shed its skin and therefore its mark. The sixth SGD-marked individual died while shedding. Over the same time period all but one ANT gecko shed its skin and mark. Each VIE gecko retained its mark for the 2-wk duration. Three individuals escaped their terrarium near the end of the experiment, but these were animals that had either been unmarked or shed their mark before escaping. A summary of shedding records and mark retention among geckos in our study is presented in Table 1. Over the course of the 2-wk study, all implanted specimens were easily distinguished upon capture, but the surface marks were consistently shed. As early as day four there were visible signs of wear to surface marks; two SGD geckos were beginning to shed, with raised skin surrounding the glue spot, but the glue itself was retained. Our results indicate that Mediterranean House Geckos might shed as often as every 2 wk under favorable conditions. Our experiment was not designed to determine if external marking promotes shedding, however, our results are suggestive of this and this warrants further testing.

For studies of *H. turcicus*, a more permanent marking method (compared to surface methods) is necessary for observation periods exceeding a few days. Toe clipping is one such alternative, but this technique has proved harmful to *Bufo fowleri* (Clarke 1972) and *Aspidoscelis* [*Cnemidophorus*] *sexlineata* (Dodd 1993). More recently, toe clipping has been shown to reduce the clinging ability of pad-bearing arboreal lizards by 40% and 60% with two and four toes removed, respectively (Bloch and Irschick 2004). The primarily scansorial locomotion of *H. turcicus* warrants consideration for the well being of their toes.

Visible implant elastomer had a minimal impact on survival, growth, health, or behavior of reef fishes (Buckley et al. 1994). Likewise, we did not observe obvious reductions in activity or locomotor performance as a result of implanting elastomer under the left knee of six *H. turcicus*. Elastomer can be used on very small animals (Marold [2001] successfully injected larval salamanders < 2 cm SVL) and, by color-coding, can be readily used to

identify individuals in a population. For example, with 2–4 injection sites on our geckos (i.e., the near-transparent undersides of knee and elbow joints), a large number of unique color combinations was possible given the availability of five readily distinguishable VIE colors, and the experimenter's own injection-pattern variability. The greater effort and higher cost of elastomer, relative to the other surface-marking methods we tested, are outweighed by the longer retention time of the VIE.

Acknowledgements.—We thank R. McCord for anecdotal inspiration and B. Joslin for advice on capture locations and capture tactics. We also thank S. Nolan, M. Sessions, and B. Adelson for field companionship and assistance and K. Wright for loan of the heat lamp. We thank G. Rodda and an anonymous reviewer for their comments. Geckos were captured under Arizona Game and Fish Department collecting permit SP636712, issued to KEB. Geckos were marked under University of Arizona IACUC permit 03–023.

The Evolution of Three Deviations from the Biphasic Anuran Life Cycle: Alternatives to Selection

RONALD ALTIG

e-mail: bcrother@selu.edu

The origins of the diversity of breeding modes in anurans beg for more focused hypotheses, but no suggestion for the evolution of any grade of endotrophy (= development without a free-living, feeding tadpole *sensu* Altig and Johnston 1989) has received rigorous testing (e.g., Salthe and Duellman 1973). Direct development occurs in at least nine anuran families (Thibaudeau and Altig 1999), and other grades of endotrophy add to the list of deviations from the classical biphasic anuran life cycle. Selection has been proposed as the process by which these various reproductive modes arose (e.g., Downie 1993; Magnusson and Hero 1991). The prevalence of these breeding patterns in species rich, tropical assemblages has presumably been caused by selection for escaping crowded (i.e., competitors) and hostile (i.e., predators and abiotic factors) aquatic habitats (e.g., Duellman 1978). Yet, hundreds of species reproduce in aquatic sites in many habitats despite experiencing low and sporadic recruitment (e.g., Greenberg and Tanner 2005). Accordingly, we should not assume that any of these reproductive deviations afford vastly superior recruitment over the typical life cycle (e.g., Roberts 1994; Rödel et al. 2002), especially when egg survival is the only criterion that is commonly reported.

In the near absence of prevailing hypotheses that address the evolution of these various developmental modes (see Callery et al. 2001), we discuss an alternative to selection. We argue for a nonhierarchical approach in a system that suggests a hierarchical structure. Adhering to a hierarchical system oversimplifies a complicated process and inhibits finding a viable solution. Many broad questions need to be answered, and only after the collection of pertinent specimens and data can we eventually revisit the larger question of the evolution of divergent reproductive modes. We discuss three reproductive grades as examples that we propose have arisen independently by different genetic mechanisms, usually multiple times: arboreal eggs, nidicolous larvae (= variously modified, nonfeeding tadpoles usually confined to a "nest"), and direct developers (= froglet hatches from egg jellies). With an understanding of developmental biology increasing daily (e.g., Gilbert 2001; Raff 1996; Robert et al. 2001), discussions of competing hypotheses should help direct future studies.

We argue that those taxa that lay arboreal eggs over water and develop normally as tadpoles achieved those capabilities via se-

HERPETOLOGICAL REVIEW

The Quarterly News-Journal of the Society for the Study of Amphibians and Reptiles

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ssarherps.org

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 2006 in the Society for the Study of Amphibians and Reptiles are as follows: **REGULAR** membership US$60 (Student $30)—includes *Journal of Herpetology* and *Herpetological Review*; **PLENARY** membership US$80 (Student $45)—includes *JH*, *HR*, and annual subscription to the *Catalogue of American Amphibians and Reptiles*; **INSTITUTIONAL SUBSCRIPTION** $115—includes JH and HR. Additional fee for airmail postage outside USA $35 for one year. Additional membership categories available on the SSAR webpage: http://www.ssarherps.org/pages/membership.html.

All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Breck Bartholomew, SSAR Membership Office, P.O. Box 58517, Salt Lake City, Utah 84158, USA. Fax: (801) 453-0489; e-mail: ssar@herplit.com.

Future Annual Meetings

2007 — Saint Louis, Missouri, 11–16 July (with ASIH, HL)
2008 — Montreal, Canada (with ASIH, HL)
2009 — Portland, Oregon (with ASIH, HL)

About Our Cover: *Acanthocercus atricollis*

East Africa's Blue-headed Tree Agamas, with their bright blue heads, live in savanna, woodland, and forest clearings, often in association with human settlements. This species can be found over much of the African continent, from Ethiopia to South Africa. Diurnal and arboreal, much of their time is spent on the trunks of big trees, sometimes on rocks and termite hills. The vividly colored, broad-headed males are strongly territorial, defending territories from elevated vantage points. Home ranges of males are markedly larger than those of females. Ants are their favored food, although a wide range of insects and other arthropods are eaten. Females lay 4–15 eggs, which undergo an incubation period of about 90 days. Hatchlings, which are 70–80 mm total length, grow rapidly and achieve sexual maturity in their second year.

The cover subject, a male *Acanthocercus atricollis*, was photographed just outside of Isasha National Park during the Exo Terra 2005 Ugandan Expedition. This eleven-person, fifteen-day expedition successfully studied the local herpetofauna. Other notable lizard species documented on this trip included *Chamaeleo xenorhinus*, *Chamaeleo johnstoni*, and *C. adolfifrederici*.

The cover photo was taken by **Michael D. Kern**, an exotic wildlife photographer living in Palo Alto, California. As winner of the 2005 Exo Terra Nactus Award, Kern was invited to be the official photographer of the Ugandan Expedition. His work has been published in several leading reptile and photographic magazines as well as nationally in many newspapers. To see more of Kern's photography, including additional images from the expedition (such as the aforementioned species of *Chamaeleo*), visit www.thegardensofeden.org. To learn more about Exo Terra and the 2005 Uganda Expedition visit www.exo-terra.com.

SSAR BUSINESS

Kennedy Student Award Committee Annual Report, 2006

The Kennedy Award Committee (Carl Anthony, Bill Lutterschmidt, Terry Schwaner, Wayne VanDevender, Lynnette Sievert, Chair) has completed its work for Volume 39 of the *Journal of Herpetology*. The Committee has selected "Critical Literature Review of the Evidence for Unpalatability of Amphibian Eggs and Larvae" by Margaret S. Gunzburger (Joseph Travis, coauthor; Vol. 39: 547–571). The Kennedy Award carries with it a cash prize of US $200 or the winner's selection of any SSAR publications valued at twice that amount. The Committee was impressed with the high quality of a number of the eligible papers.

The committee invites all student members of the Society to submit their work to the *Journal*, and encourages regular members who supervise the work of students to draw this award to the attention of those students.

Seibert Award Winners for 2006 Announced

The fifteenth annual Seibert Awards were presented at the 49th Annual Meeting of the SSAR in New Orleans, Louisiana July 12–17, 2006. These awards are named in honor of Henri C. Seibert, an early and tireless supporter of SSAR, serving as an officer for over 20 years. In recognition of outstanding student presentations at the annual meeting, a single award is given in each of four categories: Morphology & Physiology (7 presentations), Evolution & Systematics (5 presentations), Ecology (18 presentations), and Conservation (12 presentations). All winners will receive a check for US $200 from SSAR and a book from University of California Press compliments of Chuck Crumly.

The Winners—Morphology & Physiology: **Raymond A. Hernandez** (coauthors Stephen M. Secor and Robert E. Espinoza), California State University, Northridge, "Can omnivores be dietary specialists? Adaptability of gut form and function in an omnivorous lizard." Evolution & Systematics: **Julie Ray** (coauthor Richard B. King), Old Dominion University, "Long term perspective of Lake Erie Watersnake color polymorphism." Ecology: **Kurt J. Regester** (coauthors Matt R. Whiles and Karen R. Lips), Southern Illinois University, "Trophic basis of production and energy flow associated with emergence among assemblages of larval ambystomatid salamanders in forested ponds in southern Illinois." Conservation: **Tracy A.G. Rittenhouse** (coauthor Raymond D. Semlitsch), University of Missouri-Columbia, "Defining terrestrial habitat use and summer refuge sites of wood frogs in oak-hickory forests."

Honorable Mention—Evolution & Systematics: **Allyson Modra** (coauthor Ronald L. Gutberlet, Jr.), University of Texas at Tyler, "Phylogeny of *Bothrops*, *Bothriopsis*, and *Bothrocophias* species from morphological data (Serpentes: Viperidae: Crotalinae)." Ecology: **Elizabeth B. Harper**, University of Missouri-Columbia, "Density dependence in the terrestrial life history stage of two anurans." Conservation: **Natalie Hyslop** (coauthors J. Michael

Myers and Robert J. Cooper), University of Georgia, "Home range, movements, and survival of the threatened Eastern Indigo Snake (*Drymarchon couperi*) in southeastern Georgia."

The judges for 2006 were Lora Smith (Jones Ecological Research Center, Newton, Georgia), Margaret Gunzburger (US Geological Survey, Gainesville, Florida), Christopher Sheil (John Carroll University, University Heights, Ohio), Fredrick Janzen (Iowa State University, Ames, Iowa), John Maerz (University of Georgia, Athens, Georgia), Patrick Owen (Ohio State University, Lima, Ohio), Matthew Aresco (Nokuse Plantation, Bruce, Florida), Stephen Corn (US Geological Survey, Missoula, Montana), Marion Preest (Claremont College, Claremont, California), and Kirstin Nicholson (Washington State University in St. Louis).

NEWSNOTES

Declining Amphibian Populations Task Force Transition

Effective mid-2006, the Declining Amphibian Populations Task Force (DAPTF) became part of the World Conservation Union (IUCN) Amphibian Specialist Group (ASG). This merger will continue and expand the DAPTF's mission as an organization devoted to amphibian research and conservation. DAPTF's familiar newsletter, *Froglog*, will continue on a bimonthly basis. Electronic versions of back issues, as well as information for contributors, can be found at the DAPTF website:

http://www.open.ac.uk/daptf/froglog/

MEETINGS

Meetings Calendar

Meeting announcement information should be sent directly to the Editor (rwh13@csufresno.edu) well in advance of the event.

4–5 November 2006—33rd Annual Meeting, Kansas Herpetological Society, hosted by Fort Hays State University, Hays, Kansas, USA. Information: http://www.cnah.org/khs/AnnualMeetingInfo.html

6–9 November 2006—9th Reunión Nacional de Herpetología México, hosted by the Mexican Herpetological Society. Universidad Autónoma de Nuevo León, Monterrey, Nuevo León, México. Information: http://www.sociedadherpetologicamexicana.com/.

24–27 November 2006—Herpetological Association of Africa 8th Conference. Potchefstroom campus of the North-West University, South Africa. Information available from the conference website: www.wits.ac.za/haa/2006conf.htm.

6–8 February 2007—Workshop: Understanding Agriculture's Effects on Amphibians and Reptiles in a Changing World. Sponsored by U.S. Geological Survey's Amphibian Research and Monitoring Initiative, Partners in Amphibian and Reptile Conservation, the Natural Resources Conservation Service, Environment Canada, the Association of Fish and Wildlife Agencies, and Conservation International. St. Louis, Missouri, USA. Information: http://www.umesc.usgs.gov/ag_effects_workshop/workshop.html.

16–20 April 2007—First Mediterranean Herpetological Congress, Marrakech, Morocco. Information available from the Congress website: www.ucam.ac.ma/cmh1.

20–23 June 2007—31st International Herpetological Symposium, Toronto, Canada. Information: http://www.kingsnake.com/ihs/.

CURRENT RESEARCH

The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, **María del Rosario Castañeda** or **Michele Johnson**; postal and e-mail addresses may be found on the inside front cover.

The current contents of various herpetological journals and other publications can be found at: http://www.herplit.com/contents.

A New Cretaceous Terrestrial Snake: Implications for the Origin of Snakes

A new fossil snake (*Najash rionegrina* sp. nov.) is described from the Upper Cretaceous period of Patagonia in Argentina, representing the first limbed snake from a fully terrestrial deposit. *Najash* has a sacrum supporting the pelvic girdle, functional hindlimbs outside the ribcage and several features associated with a surface-dwelling or subterranean lifestyle. Previously described fossil snakes with fully formed limbs, *Haasiophis, Pachyrachis* and *Eudopophis*, from the Tethyan coasts of Northern Gondwana, were considered the most primitive snakes and the 'transitional link' between extant snakes and the Mosasauroidea, an extinct group of marine lizards, supporting the hypothesis of a marine origin of snakes. However, *Haasiophis, Pachyrachis* and *Eudopophis* also show other features typical of more advanced macrostomatan snakes (boas, pythons and colubroids) contradicting their basal position and questioning their relevance in the origin of snakes. A phylogenetic analysis of 119 characters coded for 18 relevant taxa, including all relevant fossils, shows *Najash* as the most primitive snake known and all other snake fossils closely related to more advanced recent forms. These results support the hypothesis of a terrestrial origin of snakes.

Captive Breeding and Potential Fitness Loss in a Reintroduced Species

Captive breeding has become an important conservation tool for some endangered species. Because captive populations are founded by a small number of individuals, the resulting loss of fitness due to inbreeding is usually impossible to avoid. Additional concerns result from the absence of natural selection and the rapid adaptation to captivity environments (stable, unchanging environments without predators). The authors examined whether defenses induced by predators in *Alytes muletensis*, the Mallorcan midwife toad, were maintained in populations after several generations in captive breeding. Tadpole induced responses to natural predators (the snake *Natrix maura* and the frog *Rana perezi*) under laboratory conditions include elongation of the tail, shallower tail fins, and faster development. Morphological measurements and developmental stage were compared between 1) a natural population (founder) and a reintroduced population (descendant) with common ancestry, and 2) short-term (3–8 generations) and long-term (9–12 generation) captive populations with different ancestors. Tadpoles from both founder and descendant populations showed induced changes to chemical predator cues in tail shape, with no significant difference between the two. Significant differences between short-term vs. long-term captive populations were found only in the lower tail fin, and despite no significant differences in other measurements, short-term population shape variation was stronger. Genetic variation was also studied using microsatellite DNA analysis, comparing heterozygosity and allelic richness among populations. Results suggest that relatively high levels of heterozygosity and important fitness attributes can be maintained for a few generations in captivity, but in long-term captive populations these start to decline and might have a detrimental effect in reintroduction programs.

Kraaijeveld-Smit, F. J. L., R. A. Griffiths, R. D. Moore, and T. J. C. Beebee. 2006. Captive breeding and the fitness of reintroduced species: a test of the responses to predators in a threatened amphibian. Journal of Applied Ecology 43:360–365.

Deviation from the Frequency-Dependant Selection Model of Batesian Mimicry in Poison Frogs

In Batesian mimicry a palatable species mimics the warning signal of a toxic model to deceive and avoid predation. The mimetic advantage is frequency dependant, as a considerable increase of mimics result in predators learning to ignore the warning. Where more than one model species is available, theory predicts 1) the evolution of polymorphism, so mimics diverge in appearance and are allowed to increase in abundance and maintain the warning signal in low frequency, 2) the evolution of an intermediate phenotype between model species, or 3) a mimetic resemblance to the most highly abundant and/or noxious model. The authors studied a mimicry system composed of two parapatric models (*Epipedobates bilinguis* and *E. parvulus*) that share a similar warning coloration and one mimic (*Allobates zaparo*) that is geographically dimorphic resembling each warning signal where the model is parapatric. Where the two models co-occur, *A. zaparo* resembles only one of the models (*E. bilinguis*), contradicting predictions 1 and 2. The authors used toxicity assays, field abundance measurements, and predator learning experiences to investigate the mechanisms related to this atypical case. In the area where both models occur, *Epipedobates parvulus* was significantly more abundant than *E. bilinguis*. Further, *E. bilinguis* was less toxic than *E. parvulus*. Contrary to expectations, in co-occurring areas *A. zaparo* resembles the least abundant and less toxic model. Predator-learning trials with chickens were conducted to study the psychological 'stimulus generalization' model. Predators educated with the more toxic *E. parvulus* avoided mimics of both models; however, predators educated with the less toxic model only avoided models from their learning experience. Therefore, in the area of overlap, mimics of *E. bilinguis* (the less toxic and less abundant model) received protection generated from both models. The authors suggest the resemblance of *A. zaparo* to the less abundant, less toxic model is stimulus-controlled predator generalization of learned avoidance. Alternative explanations for this pattern are also discussed.

Darst, C. R. and M. E. Cummings. 2006. Predator learning favours mimicry of a less-toxic model in poison frogs. Nature 440: 208–211.

Morphological and Functional Convergence in Herbivorous Lizards

Food capturing and acquisition requirements common to all herbivores provide similar selective pressures that could lead to convergence. The author studied functional and morphological convergence of herbivorous lizards using geometric morphometric techniques and simple functional models. Three questions were addressed: 1) do herbivorous lizards show evidence of convergence in skull and lower jaw morphology? If so, 2) what is the morphospace pattern associated with this convergence? and 3) is it possible to predict the direction of the convergence based on functional models? Relative warp (RW) analysis and a new metric of convergence (multidimensional convergence index, MCI), coupled with a resampling procedure to test for significance, were applied to digitized landmarks of adult skull and lower jaw photographs in lateral view (555 species, 13 families). Three different patterns that could be considered evidence of convergence were tested: 1) occupation of the same area of morphospace, 2) occupation of different areas of morphospace, but putative convergent taxa closer to each other than to relatives, and 3) parallel change of putatively convergent taxa away from their relatives. To test if it is possible to predict the direction of the convergence using functional models, the author compared the mechanical advantages (MA) between herbivores and carnivores, calculated from the lower jaw landmark coordinates and plotted onto warp plots. Results support a morphological convergence among herbivorous lizard skulls, based on a pattern that shows deviations of the herbivores away from their carnivore relatives and towards a common area

of morphospace (second pattern of convergence). In the lower jaws, though no overlap in morphospace occurs, there is a convergent function that can be predicted using a lever model, where herbivores tend to show higher values of MA, supporting the idea that different changes in morphology can result in the same change in function. Finally, the author highlights the importance and the advantages of incorporating functional and morphological perspectives into the same question.

Complex Ornament Evolution In Agamid Lizards

The expression of exaggerated physical features or ornaments in males, used in reproductive displays and aggressive encounters has been regarded as the result of sexual selection. However, the presence of these structures in many females remains a tricky question. Two main hypotheses have been postulated to explain the mutual ornamentation: 1) genetic correlation between sexes, and 2) sexual selection on females as well as males. The former case predicts simultaneous evolutionary gain of ornaments in both sexes, followed by an eventual secondary loss, while in the latter, the historical appearance of the ornaments does not have to occur in concert in both sexes. Using comparative analyses, the authors examined the relative contribution of each hypothesis in the mutual ornamentation of agamid lizards. On a composite phylogenetic tree, linear parsimony was used to reconstruct transitions between monomorphism and dimorphism, and for each sex separately, the gain or loss of ornaments. The Phylogenetic General Least Squares (PGLS) regression model was used to establish if type of shelter used to avoid predators might influence the number of ornaments. Results show a complex history of evolutionary transitions between no ornamentation, mutual ornamentation and dimorphism in agamids for most ornament types studied, supporting the role of both genetic correlation and sexual selection on females. The total number of ornaments exhibited by both males and females was negatively associated with burrowing behavior. Interestingly, and contrary to predictions of the genetic correlation hypothesis, the authors found that males have experienced more evolutionary losses than females for several ornament types and discuss different explanations for this pattern, including risk of predation, type of shelter used, and changes in the dynamics of natural selection (shift in direction of sexual selection, founder effect and genetic drift).

Report of the Amphibian Chytrid Fungus in Costa Rica Prior to Population Declines

The recent decline and extinction of amphibian populations from apparently protected and undisturbed areas is an alarming global trend. Population declines in Costa Rica, mostly in the mid and high elevations, have been linked to climate change and outbreaks of the amphibian fungus *Batrachochytrium dendrobatidis*. The authors studied the presence of the fungus in specimens collected at the Braulio Carrillo National Park (BCNP, 100–2600 m), in 1986 prior to well-documented declines in the area. Histological cuts from the pelvic patch of 202 specimens representing 30 species were examined. For comparison, 18 specimens from 5 species were collected in 2002 from the lower portion of the study area to establish if the chytrid fungus is currently present in lower areas, where no declines have been reported. The authors compared the infection status of host species with altitude (as a temperature indicator), reproductive mode, and current population status. Results show that the chytrid fungus was present in the BCNP in almost all altitudes in 1986, not only in species that have disappeared from the area, but also on those that have persisted as well. Furthermore it was present in the few species that can still be found in high altitudes, where the highest declines have been reported. Species of all reproductive modes were infected, except the direct developing species that inhabit streams. As it is not restricted to species strongly associated to aquatic habitats, the authors suggest the pathogen can survive in moist floors and can be picked up from the ground. In the 2002 survey three out of the five species included were infected, but all five are common and with no signs of population decline.

This study does not support the hypothesis that chytrid infections would occur only in species and sites where subsequent population declines occurred, though the authors do not deny the association between the fungus presence and population declines and highlight the role other factors might be playing in the amphibian population declines.

Habitat Microstructure Predicts the Developmental Life History of *Eurycea* Salamanders

Phenotypic plasticity, the ability to express alternate phenotypes, allows populations to colonize and survive in variable environments. The plethodontid salamander *Eurycea tynerensis*, restricted to the Ozark Plateau of south-central North America, comprises both strictly aquatic paedomorphic populations and more terrestrial metamorphic populations. Populations typically display only one life history mode. The authors tested the relationship between environmental conditions (streambed sediment) and life history (paedomorphic/metamorphic) using independent contrasts and Markov Chain Monte Carlo randomizations to test the significance

of regression results. Sediment particle size, type (clastic or chert) and degree of sorting (a measure of uniformity of particle sizes in the substrate, poor sorting = containing multiple size classes) were highly correlated with life-history mode. Paedomorphic populations were present in streams with well-sorted, large chert particles while metamorphic populations were present in streams with poorly sorted, clastic small material as sandstone or siltstone. All correlations were positive and significant. The authors suggest the streambed material composed by deposits of large gravel creates a loose streambed that allows access to subsurface water in dry months, allowing paedomorphic forms to survive, while streambeds composed of more heterogeneous, densely packed clastic sediments leave no subterranean refuge when water surface dries forcing the exploitation of more terrestrial habitats. These results suggest local microhabitat conditions have a major role in phenotypic expression. However, the authors point out that despite the strong correlations with streambed composition, other factors such as nutrient abundance, persistence of underground water, or availability of suitable surrounding habitat can be playing an important role in determining life history mode in *E. tynerensis*.

Comparison of Species Delimitation Methods Using the *Sceloporus grammicus* Complex

Accurate delimitation of species is a recurrent issue in biology, given that species are the basic unit of analysis in several areas. Recently, a series of methods have been proposed to identify and delimit species, but few studies have compared the results of different methods over the same group. The authors used the *Sceloporus grammicus* complex, composed by at least 8 chromosome races (7 of them morphologically distinguishable) to test genetic distance, character-based and tree based methods for delimiting species. Allozyme, morphology and molecular data from the literature was reanalyzed to determine hypothetical evolutionary species (HES) according to the evolutionary (ESC) and general lineage (GLC) species concepts. The authors tested if the four HES established a priori were recovered under different methods and different types of data (chromosome and allozyme). The methods applied were: 1) Highton (2000) genetic distance, 2) the character-based, Doyle (1995) multilocus field for recombination (mlFFR) and Davis and Nixon (1992) population aggregation analysis (PAA), and 3) Wiens and Penkrot (2002) tree-based method. A total of 662 lizards were included, from 55 localities, representing all chromosome races. Results showed Doyle's mlFFR had low resolution and poor ability to identify distinct lineages. Highton's genetic distance, Davis and Nixon's PAA and Wiens and Penkrot's tree based method recovered all four HES with different degrees of support. However, no single method strongly identified all four HES lineages, though no significant discordance was found between methods. The authors discuss the ability of each method to discriminate among different HES with the types of data used, and conclude that given the complexity of the group in question the results are encouraging regarding the applicability and accuracy of these three methods in delimiting species.

The Origins of Egg Eating in Snakes

Major dietary shifts often begin with the incorporation of novel food items as a minor component of the diet. However, initial stages of diet specialization are usually overlooked because they are not associated with major phenotypic changes. To study the origins of egg eating in snakes, the authors used comparative methods to test if egg eating is more likely to arise in lineages that already include squamates (lizards and snakes) or birds in their diets. This association is expected for two reasons: 1) the occurrence correlation, when a novel food is more likely to be encountered if its density is correlated with a particular food already part of the diet, and 2) the specific feeding predisposition, when traits that facilitate feeding on some food already in the diet might facilitate feeding on the novel food. Quantitative data on snake diet, including 200 species, was taken from the literature and unpublished data from one of the authors. Data on habitat and maximum size was also considered, as these variables are associated with the probability of finding squamate or bird eggs (terrestrial, arboreal, aquatic) and the capability of ingesting them (gape size). Concentrated changes test and a Bayesian estimation of character evolution based on stochastic models were applied on a supertree including all species of interest. Analyses were conducted including all the taxa, and also excluding species highly unlikely to find the eggs or corresponding animals (i.e., aquatic species) and those probably unable to eat them (i.e., small species). In addition, character mapping was used to infer whether the egg specialists arose from lineages that ate the corresponding animals. Results support the hypothesis that feeding on the corresponding animals is correlated with the inclusion of eggs in the diet and all the ancestors of egg specialist species fed on the corresponding animals. The authors discuss the results under the correlated occurrence and specific feeding predisposition explanations and emphasize specialization of egg eating can be related not only to the availability and density of the resource, but to the historical constraints the evolutionary path to specialization entail.

OBITUARIES

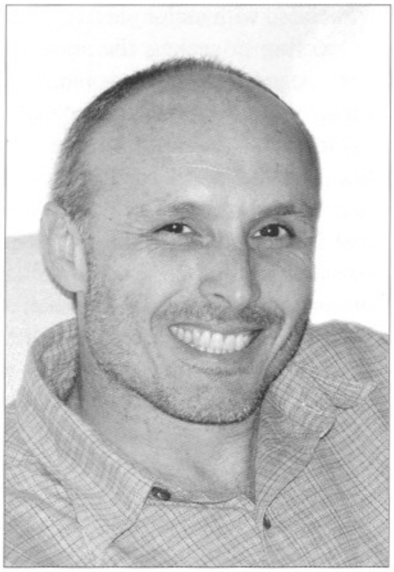
Herpetological Review, 2006, 37(3), 262.

Marcos Di Bernardo
1963–2006

ROBERTO E. REIS
Catholic Pontifical University of Rio Grande do Sul
90619-900 Porto Alegre, RS, Brazil
e-mail: reis@pucrs.br

and

FRANCISCO L. FRANCO
Butantan Institute, 05503-900 São Paulo, SP, Brazil
e-mail: flfranco@butantan.gov.br



Marcos Di Bernardo in the early 2000s.

Marcos Di Bernardo, a prominent Brazilian herpetologist and professor of zoology at the Catholic Pontifical University of Rio Grande do Sul (PUCRS), Brazil, passed away on 16 June 2006 at age 42 in Porto Alegre, following a two-year battle against cancer. Marcos was born 4 November 1963 in Bento Gonçalves, Rio Grande do Sul State, to Ayres Italvino Di Bernardo and Elisa Velenti Di Bernardo. He lived with his family in Bento Gonçalves until finishing high school and then moved to Porto Alegre to attend University and become trained as a biologist.

Marcos entered the same university in which he eventually became a professor in March 1981, and graduated with a degree in Biological Sciences in 1985. A few years later Marcos enrolled in the graduate school at the same university and received a M.Sc. degree in 1991 with a thesis on a cladistic analysis of a group of xenodotine snakes and the resurrection of *Echinanthera* Cope, 1894. In 1986 Marcos accepted his first position as a biologist, as Assistant Researcher in the Museum of Sciences and Technology of PUCRS (MCP). At MCP Marcos was a student of Thales de Lema, who guided his first steps in the field of herpetology. Together with Thales, Marcos constructed an important collection of amphibians and reptiles at MCP that today includes more than 26,000 specimens, mainly from South America. In March 1994, Marcos entered the graduate program of the State University of São Paulo (UNESP) at Rio Claro, under Ivan Sazima. He received his Ph.D. degree from UNESP in 1998 with a dissertation on the natural history of a community of snakes in the Araucaria Plateau in southern Brazil.

In March 2001, Marcos accepted the position of Adjunct Professor at the Catholic Pontifical University of Rio Grande do Sul, where he taught undergraduate courses on the zoology of tetrapods, amphibians, and biodiversity, and graduate courses in herpetology and the natural history of reptiles. During the last several years Marcos was very active in university life, serving in many university committees, teaching, and directing 13 master theses and nine doctoral dissertations. His important contributions to Brazilian herpetology include 46 peer-reviewed papers, one book, and six book chapters published during his career, most of those on natural history and taxonomy of reptiles and amphibians, and several papers co-authored with his former graduate students. He was a gifted photographer and produced thousands of wonderful images of reptiles and amphibians over the courses of many years. Marcos had a deep interest in biodiversity studies, publishing original descriptions of two new species of snake, *Echinanthera cephalomaculata* Di Bernardo, 1994 and *E. cephalostriata* Di Bernardo, 1996, and two new species of frog, *Elachistocleis erythrogaster* Kwet & Di Bernardo, 1998 and *Melanophryniscus admirabilis* Di Bernardo, Maneyro & Grillo, 2006.

In the early 1990's Marcos met Thales de Lema's graduate student Silvia Rodrigues Machado, whom he married in 5 November 1995. Tragically, Silvia died very young of a cerebral aneurism in July 2002, leaving Marcos and their daughter Camila Di Bernardo, then only three years old. Silvia's cousin and Camila's godmother Carla Nogueira assumed much of Camila's care and eventually married Marcos. Carla came to reestablish family happiness, with enormous dedication and love. This passage would have been much more painful without Carla.

Marcos was a successful field and laboratory herpetologist who loved snakes and other reptiles. He was an excellent and dedicated teacher, beloved by his students, and several times elected as Honored Teacher in graduation ceremonies. Marcos had a rare combination of virtues: he was generous without being spendthrift, was proud without being arrogant, was humble without being simple, and was serious without losing the joy of life. The happiness and the peace that he transmitted to all around him earned the affection of adults and children, as well as prominent personalities and those of more modest backgrounds. This way, he built friendship and respect everywhere he traveled. He was righteous in his beliefs, and lived to high standards, both in his personal life and in his academic and professional life. It was always a pleasure interact with him. He is now resting after the glorious fight that nobody emerges from as winner. Thankfully he will be remembered not for this final battle, but for living his life with the kind of dignity that distinguishes great men.

A devoted husband and father, Marcos is survived by his only daughter Camila and his wife Carla, and will be forever remembered with the most vivid and happy memories by those colleagues and friends that he cultivated during his life. Marcos, we all will miss you!

Acknowledgements.—We thank G. M. F. Pontes, who provided assistance in finding proper dates and helped in searching photographs, and J. S. Albert for reviewing the manuscript.

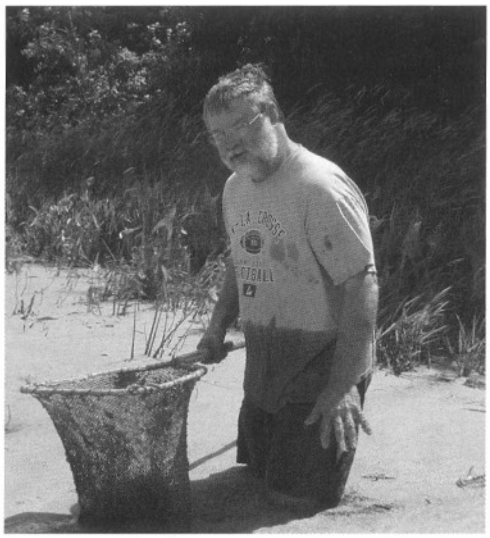
Daniel Robert Sutherland 1952–2006

JOSHUA M. KAPFER
Department of Biological Sciences, University of Wisconsin-Milwaukee Milwaukee, Wisconsin 53211, USA
e-mail: jmkapfer@uwm.edu



Dan Sutherland, pictured here, as those who worked with him in the field will remember him most fondly: slopping through wetlands, wearing shorts (never hip-waders), soaking wet, and covered in muck. This picture was taken at an amphibian malformation "hotspot" in Eden Prairie, Minnestoa. Photo courtesy of Pieter Johnson.

Daniel Robert Sutherland, Ph.D., passed away suddenly and unexpectedly on May 26, 2006 in La Crosse, Wisconsin. He was 54. He is survived, in part, by his wife of 22 years, Becky A. Lasee, Ph.D., and daughter, Alyssa (age 13).

Dan was born on March 26, 1952 in Vermillion, South Dakota to Robert and Vida (Floy). He attended high school in Wayne, Nebraska, where he achieved notable success on the football field, and graduated in 1970. Dan went on to receive his undergraduate degree in biology from Wayne State College (Nebraska) in 1974, and his master's degree in zoology from the University of North Dakota in 1976; his thesis was entitled *"An Analysis of the Piscine Parasitofauna of Four North Dakota Streams."* Upon finishing his master's research, Dan began doctoral work in zoology at Iowa State University under Professor Martin Ulmer. He completed his dissertation (*"Life Cycle and Host-Parasite Relationships of* Khawia iowensis, *Calentine and Ulmer, 1961* [*Cestoidea: Caryophyllidea*]") in 1981 and, after teaching for a year at the University of Wisconsin-Eau Claire, took a post-doctoral position at the University of Wisconsin-Madison. Dan went on to become a professor of biology at Wartburg College (Iowa) from 1987–1993. He then joined the biology faculty at the University of Wisconsin-La Crosse where he remained until his passing.

Although educated and trained as a fish parasitologist, Dan's significant contributions to herpetology are well known to those in the field of amphibian malformations. As an expert in aquatic animal health, Dan was initially drawn to the phenomenon of "deformed frogs" in the mid-1990s after it was suggested that a trematode could disrupt normal development in metamorphosing amphibians. Not long afterwards, he became heavily involved in researching the platyhelminth species *Ribeiroia ondatrae*, a parasite that has been shown to elicit amphibian malformations in both laboratory and field settings. For the past decade, Dan tirelessly collected and dissected thousands of anurans in an attempt to better understand this parasite and its effects on amphibians, quickly becoming a nationally known authority on the subject. Amphibian researchers from throughout North America would annually send field-collected anurans to him for dissection and proper identification of the parasites they contained.

He co-authored a number of important scientific papers on the subject and his research was featured in William Souder's book, *A Plague of Frogs: The Horrifying True Story* (2000), and Dan recently wrote an authoritative chapter on anuran parasites in *Declining Amphibians: The Conservation Status of United States Species* (2005).

Although an outstanding scientist and researcher, Dan will be most affectionately remembered for the passion with which he taught. Having mentored hundreds of undergraduate and graduate students (including me) throughout his professional career, Dan excelled at getting the best out of his students. Well known for his gregarious, affable personality and highly respected on campus, word quickly spread each semester among students registering for classes to "take Sutherland" for introductory biology, parasitology, anatomy and physiology, and aquatic animal health. Dan's love of field biology became apparent when he taught, as all of his parasitology students were taken to nearby wetlands to go "froggin'" and collect their own specimens to analyze in lab, something they all enjoyed. His ability to tell stories, jokes, and his good-natured ribbing of students was also legendary, quickly endearing him to those enrolled in his courses.

Dan will be deeply missed by those who considered him a colleague, a teacher, a mentor, and, most importantly, a dear friend.

ZOO VIEW

When I started in the zoo business in 1965, one of the persons I met a few years later was reptile keeper Ron Goellner from the St. Louis Zoo. A few years later, he was promoted to curator, a position he held until 1995. Since then, Ron was Director of Animal Collections. Some months ago, I learned that Ron was ill and sadly, he passed away on 26 February 2006. An expanded tribute to Ron will appear in *Herpetological Review* by two of his friends and colleagues, Jeff Ettling and Charles Hoessle. Ron was the creator of the Zoo's Center for Hellbender Conservation, now renamed the Ron Goellner Center for Hellbender Conservation. Donations can be sent to the St. Louis Zoo Foundation, P.O. Box 790290, St. Louis, Missouri 63179-0290, USA. Include a note directing funds to the Hellbender Center.

—James B. Murphy, Section Editor

Herpetological Review, 2006, 37(3), 264–268.

Herpetology at the Fort Worth Zoo: A 45-Year History

CLAY M. GARRETT*
Department of Herpetology, Fort Worth Zoo
Fort Worth, Texas 76110, USA

** Present address: Second Nature Wilderness Program*
2711 Santa Clara Drive, Santa Clara, Utah 84765, USA
e-mail: cgarrett@airmail.net

The Early Years

In late summer of 1953, members of the Fort Worth Zoological Association, notably Kirk Johnson, Amon G. Carter Jr., and Park Director Hamilton Hittson, began searching for a professional zoologist for the position of Curator of the Fort Worth Zoo. Although the search committee considered numerous candidates, it was a young chap, merely 23 years old, who piqued their interest. His name was Lawrence Curtis. Curtis, who had earned two natural science degrees from Southern Methodist University, had been working at the Dallas Aquarium for seven years, and was also gainfully employed as General Curator of the Dallas Zoo. Assistant Park Director James Brown frequently visited the Dallas facility and had been very impressed with Curtis. So on the recommendation of Brown, Hittson attempted to recruit Curtis for the position of Curator of the Fort Worth Zoo.

Curtis thoughtfully weighed the merits of each institution. He knew that Dallas was municipally supported and had no immediate plans for capital improvements, whereas the Fort Worth Zoo was supported by a strong association intent on expanding their facilities. Further lured by an increase in salary and the promise of free residence, Curtis accepted the position.

Shortly after joining the staff, he began developing a master plan, which would become the basic design of the modern Fort Worth Zoo. One of his primary goals was to add indoor facilities, for at that time the Zoo was basically a summer attraction. Curtis had a great interest in ichthyology and rather quickly sold the Zoological Association members on the value of a new aquarium. In December of 1953, Amon G. Carter Jr., presented the Zoological Association with a check for $50,000, and shortly thereafter, construction on the new aquarium began. It was named the Record Aquarium, in honor of James R. Record, dynamic Managing Editor of the *Fort Worth Star Telegram*. In two-and-half years the aquarium had drawn more than twice as many visitors as the population of Fort Worth, and had grossed $150,000, much of which was used to finance additional Zoo construction.

The following five years were busy ones for Curtis. He petitioned the Park Board for numerous improvements that included moated exhibits and a Great Ape House. In November of 1958, Curtis initiated a project that would bring the Zoo acclaim for decades. He appeared before the Park Board to announce that the Zoological Association wished to build a reptile house. After receiving authorization to proceed, Curtis flew to New York, Philadelphia, and Washington, D.C. to evaluate various herpetological facilities.

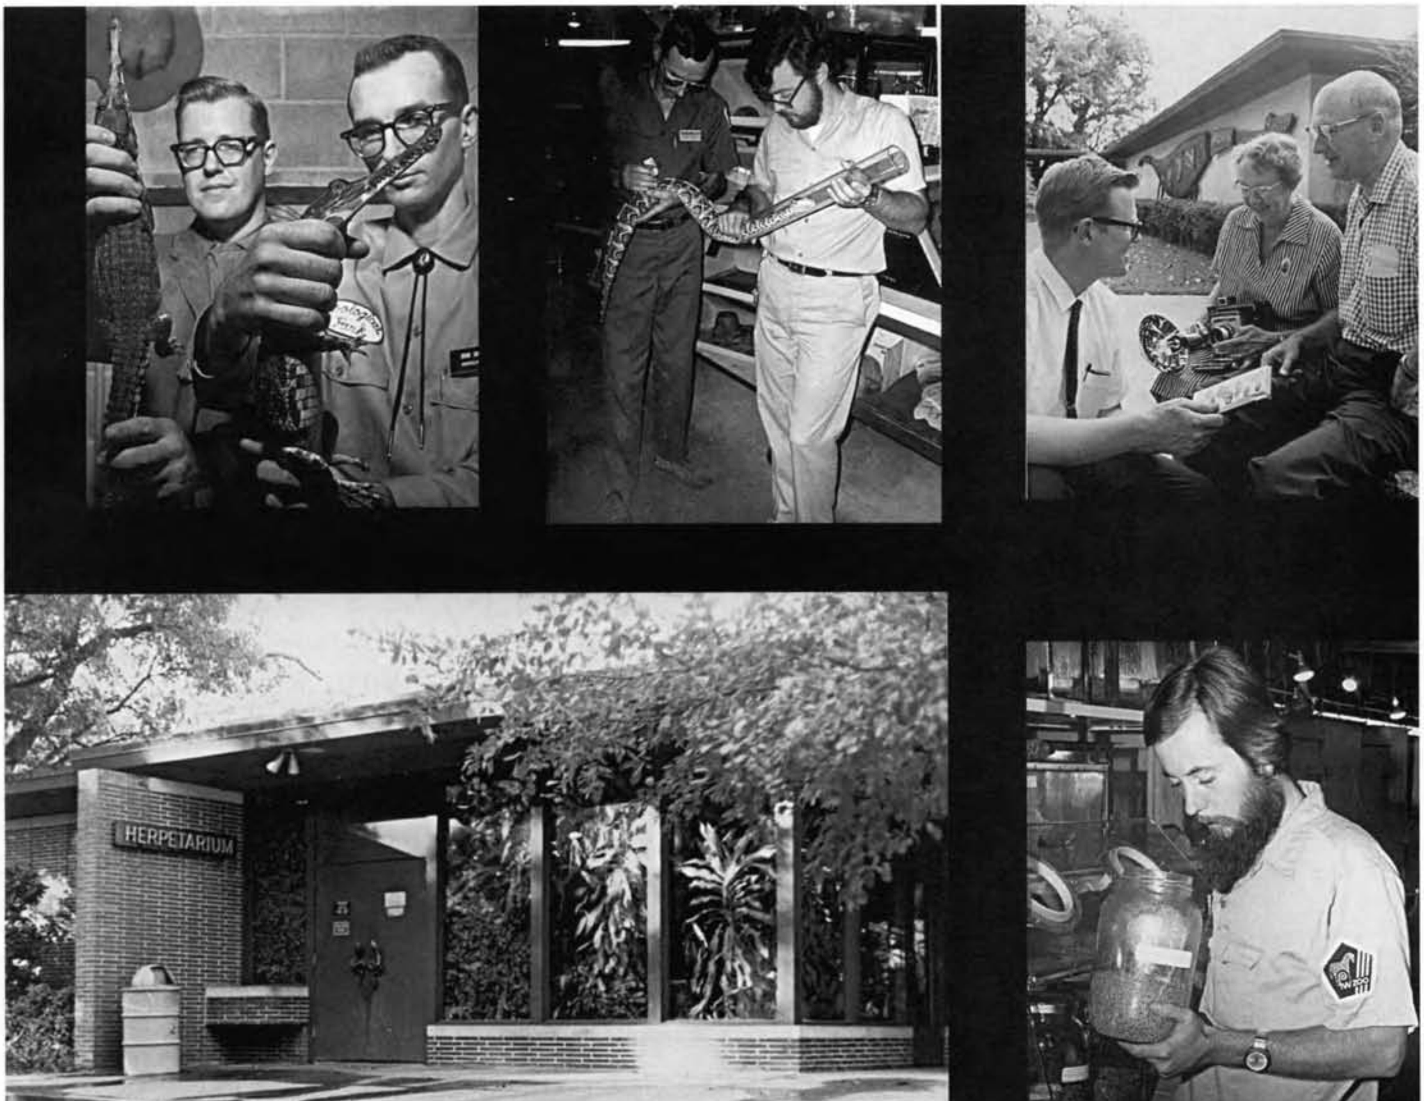
Herpetarium Construction.—In the spring of 1959, Curtis presented Herpetarium plans for final approval. The building was to measure 117 x 55 feet and cost approximately $80,000, including stocking expense (ca. 200 species). The Park Board unanimously approved the proposal, whereupon the Zoological Association received a $93,000 loan co-signed by Amon Carter Jr. The loan was to be repaid by admission fees of 10 cents for children and 20 cents for adults.

The Herpetarium was completed in the summer of 1960 and was the fourth indoor exhibit to open in less than six years. Boasting the largest exhibit of reptiles and amphibians in the world (with 175 vivaria), the facility also included a Zoo hospital and quarantine room. Then contemporary features, such as refrigerated air, operational skylights, temperature controlled water, switch operated emergency alarms, and state-of-the-art service facilities, made this Herpetarium a true marvel. Innovative exhibits such as a display of giant snakes with curved non-reflective glass (creating the illusion of an open-fronted exhibit) were especially popular attractions. The main public area included five exhibit halls covering various geographic regions and another area that was devoted exclusively to amphibians. There were also special exhibits teaching the identification of native venomous snakes and treatment for snakebite.

Staff

Lawrence Curtis had a passion for herpetology that rivaled his interest in ichthyology. In the 1950s he authored papers in numerous journals such as *Copeia*, *Herpetologica*, and the *Texas Journal of Science*. He also contributed regularly to *International Zoo Yearbook*. Over the years he held many board positions including Vice President of the Texas Herpetological Society and President of the American Association of Zoological Parks and Aquariums (now AZA – American Zoo and Aquarium Association).

Curtis was one of the first herpetologists to keep an up-to-date catalogue on antivenin. During the summer of 1966, a young boy—the victim of a rattlesnake bite—was saved after receiving antivenin treatment. Curtis consulted his antivenin catalogue and coordinated the serum shipment to Texas via the US Air Force. Before the year's end, he aided several other people from various states. In recognition of his services he received several awards from the American Aviation Association and the Press Club of Fort Worth. Further, Fort Worth Mayor Willard Barr proclaimed August 15, 1966, as "Lawrence Curtis Day."



Top Row (L to R) — Lawrence Curtis and J. P. Jones; J. P. Jones and Jonathan Campbell; Lawrence Curtis and Roger and Isabel Conant; *Middle Row* — Herpetarium as it appeared shortly after construction; Bern Tryon; *Bottom Row* — David Blody; George Ledvina; Rick Hudson.

After leaving the Fort Worth Zoo, Curtis became Director of the Oklahoma City Zoo in 1970—a position he held for 15 years. In later years he served as a consultant for various zoos and aquaria around the world, and he recently lived in Saudi Arabia where he worked as Director of the Riyadh Zoological Gardens. He presently lives in Oklahoma.

The first Supervisor of the Herpetarium was John M. Mehrtens. He was partly responsible for the quality design of many exhibits in the Herpetarium. Over the years he traveled to many locations, securing animals for display. Mehrtens is probably best known for his book *Living Snakes of the World in Color* (Sterling Publishing, 1987).

Joseph Laszlo, well known internationally for his significant contributions to our understanding of captive management, furthered his career at the Fort Worth Zoo under John Mehrtens. Joe was a colorful character to say the least. He was always eager to talk herpetology and he pursued his interests with unbridled passion. Joe was promoted to Assistant Supervisor in the mid 1960s, and later worked at the Houston Zoo before accepting the position of Supervisor at the San Antonio Zoo in the early 1970s.

John P. Jones was hired as Supervisor in the late 1960s—a position he held for many years. J. P. was a talented man who understood the art of exhibit design, graphic display, and the science of animal husbandry. Moreover, he led a fine crew of young men, some of whom would go on to make significant contributions to herpetology.

Contemporary with Jones was a young stalwart named Jonathan Campbell. Campbell was Assistant Supervisor at the time and had already begun to blaze a herpetological path of accomplishment that would prove difficult to follow. Back in those days he traveled frequently to Mexico and Guatemala with various colleagues, bringing home all manner of reptiles and amphibians—many of them new to science. Campbell left the department in the early 1970s to pursue his master's degree under William Pyburn at the University of Texas at Arlington. Afterwards he wrapped up his graduate studies at the University of Kansas, under William Duellman, where he earned his PhD in 1983. Some of Campbell's early publications covered husbandry techniques and behavioral observations in captivity. He subsequently produced a wave of manuscripts and books that included myriad new species descriptions and taxonomic revisions, mostly on Latin American herps. Campbell now holds a professorship at the University of Texas at Arlington where he is also Chair of the Biology Department and Director of the Amphibian and Reptile Research Diversity Center.

Bern Tryon joined the department in the mid-1970s as Assistant Supervisor. Modeled in the Carl Kauffeld tradition, Bern was another zoo herpetologist who bridged captive management with academic pursuits. He published many peer-reviewed papers on topics such as breeding and rearing bog turtles and captive reproduction of West African dwarf crocodiles, a paper widely regarded as one of the classic studies on crocodilian reproductive behavior. His paper entitled *How to Incubate Reptile Eggs* stands today as the standard cited reference on this topic. Bern's publications helped advance the state of chelonian husbandry, but two of his enduring passions during this time were developing breeding techniques for Arizona Ridge-nosed Rattlesnakes and Gray-banded Kingsnakes. Bern presently lives in Tennessee where he serves as Director of Animal Collection—Herpetology at the Knoxville Zoo.

One of the hallmarks of the Fort Worth Zoo's Herpetarium was the naturalistic quality of the exhibits. The departmental personnel began using live plants to enhance exhibits at a time when this practice was considered anathema (or before this practice became vogue). When it came to quality in herpetological exhibitry, one keeper stood head and hands above the rest—Fort Worth-raised David Heckard. Lead keeper in the department until 1981, David brought an attention to detail for exhibits that was unequaled. David went on to manage the Herp Department at the Abilene Zoo in Texas for many years before moving to San Diego Zoo's Wild Animal Park where he is presently employed.

Certainly one of the more colorful and intense curators in the department's history was Dave Blody. Dave had an unparalleled passion for the "herp of the moment." The result of his addiction was a burgeoning collection that stretched the resources of the department. Dave's primary husbandry interests included arboreal crotalids, boids, and varanids. He was particularly adept at making the drafty and poorly insulated Herpetarium work to his advantage by shuffling animals to appropriate niches, thus inducing many of his charges to reproduce. Perhaps his legacy will be that he oversaw the transformation of an aging and deteriorating facility into a showcase for rare herp species that attracted legions of reptile enthusiasts and became world renowned for successfully breeding difficult-to-manage species.

Rick Hudson was hired in 1980 as Assistant Curator. A Virginia native with degrees in biology and veterinary technology, Rick arrived at a time when the mystique of Texas zoo herpetology was at its peak and the collection in Dallas across the river to the east was earning its highest accolades. Fueled by a competitive spirit to excel, Rick was at once Dave Blody's "partner in crime" and together they built a reproductive program rivaled only by the Dallas menagerie.

Early on Rick became involved in the emerging AZA conservation programs for reptiles, founding and chairing the Lizard Advisory Group for more than ten years. This led to the development of the Rock Iguana Species Survival Plan (SSP) and the Jamaican Iguana Recovery Program, which received the AZA's International Conservation Award in 2000. For years he has worked tirelessly on this project and has played an integral role in the survival of the species. Expanding on this work to include the conservation of other Caribbean iguanids, Rick helped organize the IUCN Iguana Specialist Group, now in its 10th year, which he currently co-chairs. In this capacity, he devotes 50% of his time to traveling, doing fieldwork, building head-start facilities, and organizing reintroduction and recovery programs. To fund and support these efforts, he helped create the International Iguana Foundation in 2001 and serves as the Executive Director. He has long had a special interest in crocodilians and chelonians, and in 2001 organized an international workshop to address the Asian Turtle Crisis. That led to the formation of the IUCN Turtle Survival Alliance that he co-chairs, which raises funds, conducts workshops, and administers conservation programs in five Asian countries. Rick worked in the Herpetarium until 2000, whereupon he became one of the zoo's Conservation Biologists.

Jack Cover, a native of Baltimore, Maryland, was hired as Lead Keeper in the early 1980s. Jack worked at the Fort Worth Zoo for several years where he made significant contributions to the overall program. Jack was a great exhibit artist, published numerous

papers, and was particularly adept at enticing animals under his care to reproduce. Jack left the Fort Worth Zoo in the late 1980s to take a position at the National Aquarium at Baltimore, where he presently serves as General Curator.

Other former staff members worthy of mention are: Johnny Banks, Steve Boyd, Kelly Bradley, Amy Bridegam, Gary Carl, Chris Davis, Steve Dobbs, Ricky Green, Norm Haskell, Terry Hulsey, Randy Johnson, Tim Jones, George Ledvina, Tommy Logan, Doug Mehaffey, Steve Meyers, Ken Morgan, Nate Nelson, Norman Nunley, Rick Reed, Jeff Ross, John Simmons, Marc Spataro, Mike Stewart, Earl Turner, and Mark Wanner.

Currently the department has eight staff members: Curator Diane Barber, Lead Keeper Matt Vaughan, and keepers Grant Ashmore, Andrew Brinker, Mike Doss, Andrea Floyd, and Stephen Hammack.

Captive Reproduction

During the late 1970s and early 1980s herpetologists were finally beginning to grasp the fundamentals of husbandry science—made possible by pioneering studies on sex determination, thermoregulation, hibernation, habitat selection, UV light requirements, social behavior, etc.

The Fort Worth Zoo Herp Department has always had an impressive collection and a staff motivated to provide their animals with the environmental/social conditions necessary to reproduce. In 1988 the department was awarded the prestigious AZA Edward H. Bean award for their breeding program for five species of arboreal boids. Over the years staff elicited reproduction in more than 220 species (crocodilians, 6 species; chelonians, 25 species; lizards, 58 species; snakes, 120 species; anurans, 15 species) resulting in the production of more than 6000 offspring.

Conservation

Staff members at the Fort Worth Zoo have a rich history of involvement in conservation projects. In 1993 the Zoo established a Conservation Department to more actively participate in global programs aimed at habitat protection and species conservation. Although the members have an interest in many non-herp programs, reptile and amphibian projects have always been, and continue to be, an integral part of their overall conservation vision. Herpetology staff is actively involved in the Conservation Department's programs and also pursue projects independently. The following is a brief summary of ongoing herp projects.

Anegada Iguana, *Cyclura pinguis*

In an effort to save *Cyclura pinguis*, the World Conservation Union (IUCN) Iguana Specialist Group, along with the British Virgin Islands National Parks Trust, initiated a head-start program to bolster the wild population until many of the problems facing the iguanas could be minimized or removed. This project is partially funded and managed by staff at Dallas Zoo, with staff from the Fort Worth Zoo providing field support and nutrition studies. The San Diego Zoo's Center for Research of Endangered Species (CRES) also has an active role in this program.

Puerto Rican Crested Toad, *Peltophryne lemur*

In an effort to save this species from extinction, a Species Survival Plan (SSP) was created in 1984. The SSP goals include island-wide education and outreach, research, the protection of existing habitat, and the creation of new ponds. A reintroduction program is a large component of the recovery plan for this species. Each year, captive toads from zoos and aquaria in the United States and Canada are reproduced, and tadpoles are sent to Puerto Rico for repatriation.

In late 2006 program participants will begin a nutritional/dietary analysis of wild tadpoles, and continue a hydrology study on the remaining breeding pond and release sites. Zoo veterinarians will initiate a health assessment study on Marine Toads that are sympatric with the Crested Toad.

SSP Partners are American Zoo and Aquarium Association, Puerto Rican Department of Natural Ecological Resources, U.S. Fish and Wildlife Service (USFWS), University of Puerto Rico, Juan Rivero Zoo, and citizens of Puerto Rico.

Chiricahua Leopard Frog, *Rana chiricahuensis*

Listed as threatened without critical habitat, the Chiricahua Leopard Frog is in decline in many locales across its range. The Fort Worth Zoo has set up a head-start facility where adult frogs from select populations will be bred and resulting tadpoles returned to the field for repatriation.

Partners are USFWS, New Mexico Game and Fish Department, Arizona Game and Fish Department, and Turner Endangered Species Fund.

Jamaican Iguanas, *Cyclura collei*

Shortly after the rediscovery of the Jamaican Iguana in 1990, the Durrell Wildlife Conservation Trust funded initial field work and began to establish husbandry protocols. Subsequently the Fort Worth Zoo began raising funds to further support field research. To formulate a consensus, conservation, and recovery strategy, the Zoo organized a Population and Habitat Viability Assessment workshop in Kingston. Conservation actions were focused on reversing high juvenile mortality due to mongoose predation and called for collection of hatchlings for an expanded head-start program at the Hope Zoo, increased field research, predator control, and an eventual restocking program. In 1994 a team from the Fort Worth Zoo constructed an iguana management and head-start facility, and by 1996 the first pilot releases of iguanas had occurred. Since then the Zoo has conducted nutritional studies, coordinated genetic research, and performed veterinary health assessments. Training of Hope Zoo staff has been ongoing, both in Jamaica and in the U.S. The reintroduction program continues today and since 1996, 76 sub-adult Jamaican Iguanas have been successfully repatriated to the wild in order to boost the remnant population surviving in the Hellshire Hills. In 2002 a milestone was reached when a released iguana appeared at one of two known nesting sites and laid eggs, evidence that head-started iguanas were becoming integrated with the wild population. Today the Jamaican Iguana is recognized as one of the world's leading conservation success stories, and reinforces the concept that captive populations, when properly managed, can be highly relevant to conservation.

Future Plans

Following tradition, the Herp Staff will continue to showcase a diverse collection and focus on the captive reproduction of rare or little-known species. With conservation and in-house research playing an increasing role in the department's master plan, staff members will further expand their ties with the academic herp commu-

nity to more broadly define and address issues of importance.

As the department nears its 50th anniversary, staff are completing plans and raising funds for a new state-of-the-art herpetarium. This improved facility will provide increased off-exhibit holding space, as well as a more dynamic public display that presents naturalistic exhibits with an educational theme of conservation and stewardship.

Acknowledgments.—Numerous people provided information and materials for this manuscript. Some of the information regarding the early history of the Zoo and Herp Department was gleaned from newspaper clippings from the Fort Worth Star Telegram, and an unpublished master's thesis written by Texas Christian University graduate student Paul Pearce in 1969. For various courtesies I thank Diane Barber, David Blody, Margaret Hobart, Rick Hudson, James B. Murphy, Lyndsay Nantz, Tracy Sturrock, Tarren Wagener, Bob Wiese, and members of the Fort Worth Zoo Herp staff.

". . . THAT HE HAD RECEIVED INFORMATION FROM THE INHABITANTS OF THAT ISLAND, THAT IN THE NEIGHBOURHOOD OF LABOEAN BADJO, AND ON THE ISLAND OF KOMODO OCCURED [SIC] A VARANUS SPECIES OF AN UNUSUAL SIZE. THEY CALLED THE ANIMAL 'BOEAJA DARAT' (LAND CROCODILE)."—P. A. OUWENS (1912)

"THE PUBLIC SEES THE KOMODO DRAGON, WITH ITS AWESOME MORPHOLOGY AND UNSETTLING FEEDING BEHAVIORS, AS A COMBINATION OF CROCODILIAN, LIZARD, AND DINOSAUR - A CREATURE THAT MERCILESSLY TRACKS AND DEVOURS ITS PREY. THIS AMALGAMATION OF FEAR, RESPECT, AND ADORATION HAS DRIVEN THE RESEARCH MACHINE FOR MANY YEARS."—KURT AUFFENBERG AND WALTER AUFFENBERG (2002)

"HOWEVER, THOUGH BURDEN (1928) STATED THAT THERE IS NO INDICATION ORAS WILL ATTACK MAN, SOME INDIVIDUALS ARE DECIDEDLY AGGRESSIVE, AND ATTACKS ON HUMANS HAVE OCCURRED ON SEVERAL OF THE ISLANDS . . . ORAS WERE INVOLVED IN TWO DEATHS ON KOMODO."—WALTER AUFFENBERG (1981:320)

"ACCOUNTS OF HUMANS BEING KILLED OR INJURED BY KOMODO DRAGONS HAVE BEEN DOCUMENTED ONLY IN LOCAL CASUALTY RECORDS OF THE MANGGARAI PROVINCE IN WESTERN FLORES ISLAND."—DENNIS R. KING, ERIC R. PIANKA, AND BRIAN GREEN (2002)

In 1926, the first living Komodo Dragons (*Varanus komodoensis*), known as "Oras" in Indonesia, were placed on exhibit in New York's Bronx Zoo (Fig. 1) and the Amsterdam Zoo (Fig. 2), but the effort to display them in New York was less than satisfactory. W. Douglas Burden (1927) painted this gloomy picture, "After watching these great carnivores in the wilderness of romantic Komodo, it was painful to see the broken-spirited beasts that barely had strength to drag themselves from one end of their cage to the other. Surely, it is not all a matter of diet and a change of climate. Perhaps, as in the case of many mammals, *Varanus komodoensis*, in order to survive, demands the freedom of his rugged mountains." In 1934, a dragon on display at the Smithsonian's National Zoological Park (NZP) lived only two years after capture by the Griswold-Harkness expedition (Fig. 3). Five dragons were exhibited at NZP over a forty-year span, the average longevity being five years and the maximum being 12 years (Fig. 4). Because the largest specimens were generally captured, dragons at other North American and European zoos fared poorly as well (see Flower 1937; Jones 1965; Rookmaaker 1975), no doubt due to the fact that adult animals often have difficulty adjusting to captivity. Dragons rarely lived beyond five years in captivity, and most did not survive the first few months. Zoo visitors were excited about viewing these huge, carnivorous lizards, so collecting expeditions to Komodo were mounted to secure specimens for display until World War II brought collecting to an end for many years.

FIG. 2. Komodo dragon with keeper at Natura Artis Magistra in Amsterdam photographed between 1926 and 1931. Komodo dragons were added to the collection in 1926. Five years later, 12 eggs were laid in a hole and protected by the female. Note tortoise in back right corner of exhibit. Credit: provided by Eugène Bruins, Natura Artis Magistra Archives.

At the London Zoo, several intriguing reports on dragon behavior seemed to contradict the belief that dragons were always dangerous to man and were delicate captives. Hill (1946) mentioned a dragon at the Zoo pushing a shovel over the stones in his cage... "and the more noise he can make with it, the more it seems to please him." Curator of Reptiles Joan Beauchamp Procter (1928) discussed tractability and tameness, "The dragon, whose name is Sumbawa, walked around a very long table, and without paying attention to the audience ate a large fowl, several eggs, and a pigeon from her hand, allowing itself to be scratched and patted even when swallowing the fowl with enormous gulps, treatment

FIG. 3. Keeper Roy Jennier next to "Xomo," the first Komodo dragon at Smithsonian National Zoological Park. This lizard was collected by Griswold-Harkness expedition in 1934, cost $780 at that time, and lived two years. Hot water pipes in rockwork provided heat. This image was duplicated in color on a postcard for sale. Photograph courtesy of Smithsonian National Zoological Park Photo Archives.

which even dogs will not always permit." and "She [at death proved to be a male] would tear a pig to pieces but can be trusted with children." Sumbawa was the host at children's tea-parties a few weeks after arrival at the Zoo and was perfectly tame with all the guests. Procter (1928–1929) included a photograph of a two-year-old child standing next to Sumbawa (Fig. 5) and examined dragon behavior, "The question of the ferocity of these lizards is, perhaps, the most misunderstood of all. All the lizards of the genus *Varanus* are savage, predatory, and highly strung, and they use their teeth, claws and slashing tails with great effect, as I have personal cause to know. At the Zoo we consider any large monitor more dangerous to deal with than a crocodile twice its size. But, allowing for this, *V. komodoensis* is the gentlest, most intelligent, and most tractable of them all. This is comparing them with speci-

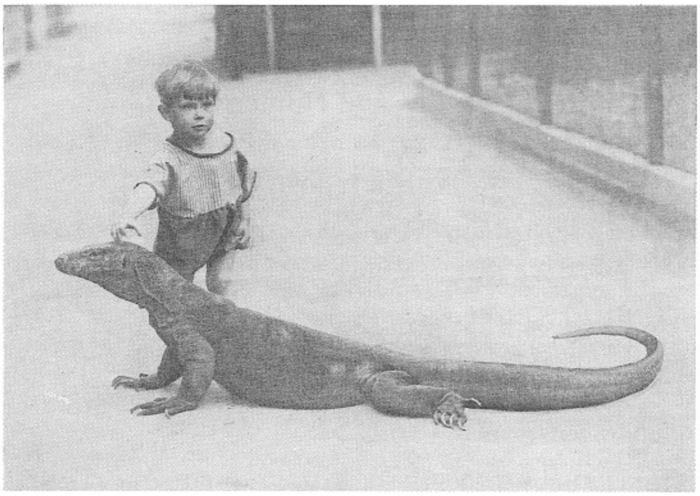

FIG. 5. Photograph by F. W. Wood of Sumbawa standing next to two-year-old child from Joan Procter's article "Dragons that are alive to-day," published in Wonders of Animal Life in 1928–1929. Photograph courtesy of Kraig Adler.

mens only half their weight of species such as *niloticus, albigularis, bengalensis, salvator, nebulosus, varius*, and so on. It is quite true that they are very nervous, and also that they could no doubt kill one if they wished, or give a terrible bite when taking food from the hand greedily, but there is no vice in them." Sumbawa accompanied Procter on strolls through the Zoo during her inspections, ". . . investigating everything which might be of interest." The lizard responded to the voice of its keeper or curator, but disliked having its tympanum touched. There is a photograph of keeper Arthur Budd with Sumbawa in 1928 (Zuckerman 1976); the scar on the lizard's neck was caused by a crocodile bite. Peter Chalmers Mitchell, Secretary of the Society from 1902 to 1935, concluded in 1929, ". . . the better conditions for the reptiles themselves and the feeding and handling of them has made some unexpected creatures docile. Notable instances are the Komodo dragons, which are as tame as dogs and even seem to show affection."

Robert Mertens from the Senckenberg Museum in Frankfurt, Germany acquired two dragons from Mr. H. R. Rookmaaker on Flores (Mertens 1930; see also Rookmaaker 1975). Mertens (translated from German) described the affair, "The next day we met the zoologically very interested assistant-resident of Flores, Mr. Rookmaaker, who immediately showed his willingness to support our expedition in any way. I was especially pleased when Mr. Rookmaaker agreed to comply with my request to get me a Komodo monitor for the Senckenberg-Museum. As the Island of Komodo had been thoroughly investigated the previous year by the American Burden-expedition, it would hardly have served any purpose to visit the Island by ourselves, as a visit to Komodo would have cost a lot of time and money. Mr. Rookmaaker showed great kindness by sending a small expedition of natives from Laboean Badjo, on the West coast of Flores, to the Island Rintja—in between Komodo and Flores—to catch a *Varanus komodoensis* for me; I would then travel to Reo, on the North coast of West-Flores, to collect this valuable animal that would be transported there from Laboean Badjo . . . As the larger *Varanus komodoensis* still persisted in refusing to take food, we decided to kill the animal, in order to prepare the skin and skeleton in a leisurely manner. After

we had tried in vain to kill the animal with chloroform [Mertens uses the term 'chloroformieren'] I reached for the needle and after an injection of 5 ccm nicotin and 10 ccm sublimate it died within a few minutes. The smaller specimen on the other hand quickly decided to start feeding: chicken eggs, chicken entrails, and veal were taken regularly. Mr. Rookmaaker now kindly gave us this lively specimen for the Frankfurt Zoo, while he courteously donated the larger specimen to the Senckenberg-Museum." There is a picture of the live dragon with a rope around its pelvic area. In 1942, curator Gustav Lederer described the habits of this tame dragon named Bübchen which lived at the Frankfurt Zoo between 1927–1944. It was taken on long walks through the zoo by the director. The dragon was in excellent health up to its death from an Allied bombing raid in which the Aquarium was demolished, thus living 16 years, 8 months, and 21 days. In Lederer's 1942 paper, there is a photograph of a woman with this large dragon. Some reptiles can recognize their keeper and are able to distinguish him from other persons. At Frankfurt, the dragon knew the veterinarian after the second treatment and could no longer be persuaded to leave its hiding place as soon as the vet appeared. The lizard even recognized the operating table and fled from it (Lederer 1931). Keeper Albert Schick allowed zoo visitors to interact with a dragon outdoors at the Frankfurt a. M. Zoo (Figs. 6, 7).

Two dragons from Rintja arrived at the Berlin Aquarium in 1927—"Max and Moritz"—presumably named after the characters from a famous old German book for children (Sachs 1927; Jones 1985; Fig. 8). Moritz lived until 1944. There is another photograph of a Berlin dragon with its keeper in a publication by Klingelhöffer (1957:247). Jürgen Lange (1989) reported on a pair of dragons from Flores which arrived at the Aquarium during May 1984, "During the first two months after their arrival both the monitors were aggressive toward visitors so viewing was restricted to the narrow sides of the terrarium and the public prohibited from touching the glass. Since then, however, they have become very tame and show no fear of their keeper."

The first dragons arrived at the Antwerp Zoo in 1930 but these lizards lived only a few years. Seven years later, other dragons began arriving at the Zoo but these varanids also lived a short time. In 1959, Walter Van Den Bergh published two interesting photographs. One pictures the chief guardian of reptiles, J. Van Gorp, next to two large dragons which became tame only a few days after arrival. The other photo shows a dragon being held by its forelegs in an upright position.

In 1937, the only zoo in Indonesia to have dragons was Surabaya. Two years later, on occasion of the 75th anniversary of the then-Dutch Zoo of Batavia (Jakarta), a book was published: "Bataviasche Planten- en Dierentuin 1864–1939" with photographs of the dragons in that old zoo and also a special chapter dedicated to them. There is an account of an expedition that would fulfill an old wish of the Zoo's board—to offer some of these dragons for sale to other zoos. The Ministry of Economic Affairs supported an expedition to collect lizards for Rotterdam, Antwerp, Rome, Edinburgh, Washington, and Philadelphia zoos. They left for Laboen Badjo in early June 1937 and decided to catch dragons by using wooden traps. The traps were baited with deer and pig meat. Only one young dragon was caught but the traps attracted a lot of very skinny dogs so they switched to the methods used by the natives—using wire traps—something they initially had wanted to avoid because of potential damage to the monitors. There is no mention on how many were caught or whether any were shipped

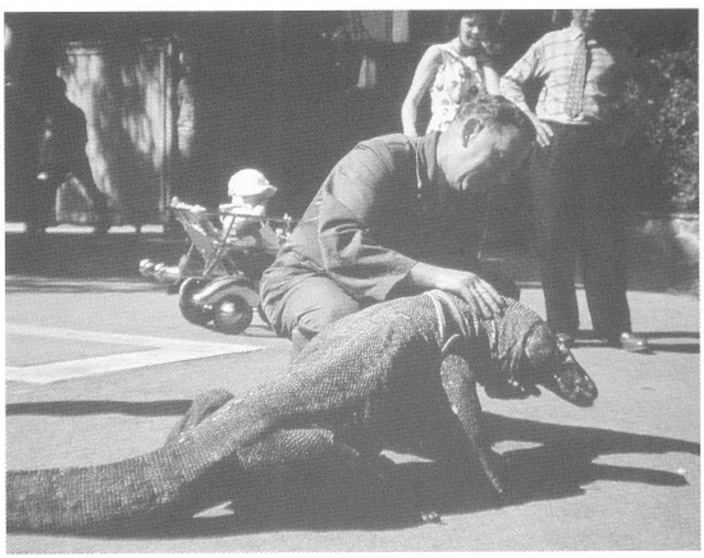

FIG. 7. This adult Komodo Dragon, with keeper Albert Schick, was allowed to walk among zoo visitors at Frankfurt a. M. Zoo in Germany. When the lizard arrived at the zoo in 1958, it measured 2.5 m. Photograph by R. Faust, courtesy of Christian Schmidt.

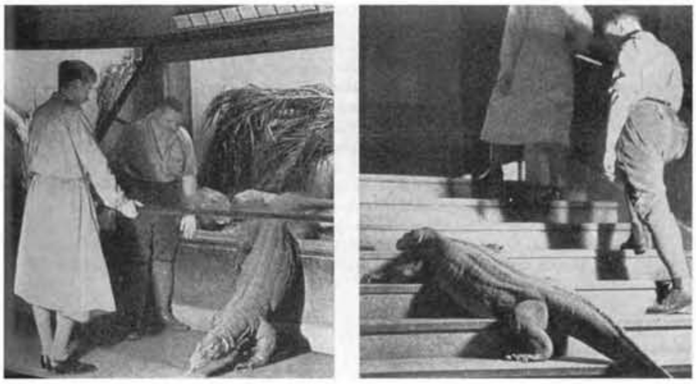

FIG. 8. Moritz, an adult male Komodo Dragon at the Berlin Aquarium. Two dragons from Rintja arrived at the Aquarium in 1927 and Moritz lived until 1944. The other dragon (Max) died shortly after arrival. Moritz is climbing out of his terrarium in the Aquarium and following his keeper like a dog. Photograph courtesy of Archive Zoo-Aquarium Berlin.

FIG. 9. Kraken with Trooper Walsh during one of the experimental trials to determine play behavior at Smithsonian National Zoological Park in 1999.

FIG. 10. Keeper Rob Lewis records Kraken's behaviors during experimental trials to determine play behavior at Smithsonian National Zoological Park in 1999. Photograph by Trooper Walsh.

FIG. 11. Kraken begs pizza from a familiar volunteer at Smithsonian National Zoological Park, 1998. Photograph by Trooper Walsh.

to foreign zoos.

In the National Geographic School Bulletin published on 10 October 1960, a cover photo said to be taken at the Rotterdam Zoo shows a young child walking with a large dragon controlled by a rope harness around its body.

Until recent decades, captive dragons have not been thoroughly investigated, due to lack of success in maintaining viable populations. At the NZP in 1995, a young female named Kraken, approximately 2.5 m in total length and hatched at the Zoo three years earlier, usually exhibited playlike behavior—removing a

FIG. 12. Kraken investigates unfamiliar visitor at Smithsonian National Zoological Park, 1998. Photograph by Trooper Walsh.

handkerchief or notebook from keeper Trooper Walsh's pocket, scraping his shoes with her forearm, playing tug of war with a plastic cup, interacting with empty cardboard boxes, as well as pieces of cloth and scarves (Fig. 9). Kraken stood on her hind legs, directed tongue flicks to Walsh's face, rested her head on his shoulder, and closed her eyes. Kraken carried frisbees, shoes, plastic toy action figures for children, and other objects around in her mouth but made no attempt to swallow them (Fig. 10). The lizard stuck its head into a plastic bucket, raised her anterior trunk so that the container covered her head and walked around the exhibit. The dragon placed her snout inside a shoe, lifted it off the substrate, and moved throughout the cage. When Walsh whistled, Kraken turned her head toward the source of the sound. Kraken could discriminate between prey and non-prey; she would gently take a rat offered with tongs and never showed an inclination to bite Walsh. See Burghardt et al. (2002) for an initial behavioral inventory and quantitative analysis of the trials with Kraken.

Not all dragons are placid toward humans, however. Walter Auffenberg (1995, pers. comm.) told us about a large rogue dragon (later identified as # 34) tracking his fifteen-year-old son Kurt and field assistant Putra Sastrawan during his study on Komodo Island. Kurt and Putra took a small trail from the base camp to work in Poreng, a pass over the mountain ridge that separates the northern and southern watersheds of the island. People used this trail to go to Sabita, a village on the northeast coast. This dragon entered their tent, tore apart articles of clothing, and carried off a soiled handkerchief. When they returned to base camp the next day, # 34 walked up to the house, laid its chin on the deck and watched them. Kurt recognized # 34 and suspected that the lizard had tracked them which was confirmed when they returned to the trail the next day; the dragon's tail drag was superimposed over their footprints. Remarkably, this dragon had tracked Kurt and Putra from Poreng back to the base camp, a distance of several kilometers. Walter interpreted this as a potential predatory episode. Of the 55 hatchlings produced by the NZP female between 1992–1995, at least two were aggressive toward humans at hatching and remained so through adulthood.

FIG. 13. Ultrasonography of dragon at London Zoo in 2005. Photograph courtesy of Richard Gibson, Zoological Society of London.

There are a number of research projects currently running or recently completed at several zoos. At the Dallas Zoo, Curator Ruston Hartdegen and associates have discovered that a dragon could discriminate between its permanent keeper, another reptile keeper who had less contact with the dragon, and a keeper from another animal department. The dragon was calm with the familiar caretaker, nervous around the less-familiar reptile keeper, and displayed defensive behavior to the keeper from another animal department (R. Hartdegen, pers. comm.). Kraken at NZP exhibited the same responses toward familiar and unfamiliar persons (Figs. 11, 12).

At the London and Houston zoos, ultrasonography without anesthesia is used to determine sex and assess reproductive condition on dragons; the dragons remain calm during the procedure (Fig. 13).

In London, a large male dragon (named Raja) was in a restraint box for target training (Fig. 14). Dragons are trained to associate a target on a stick with a food reward. The target is moved into and out of the restraint crate so that the dragons become comfortable entering this restricted space, which facilitates moving them. This interesting example of operant conditioning used food as the initial cue—then the reward frequency was gradually reduced, using

FIG. 14. Large male dragon named Raja in restraint box for targeted operant training to allow bleeding, nail clipping, physical examination, and other procedures requiring handling. Photograph courtesy of Richard Gibson, Zoological Society of London.

FIG. 15. Dolly Ellerbrock and dragon named No-Name at Pittsburgh Zoo. This enormous male dragon is called "No" by the staff and comes to them when called. No-Name hatched at Smithsonian National Zoological Park in 1993 and now measures approximately 3 m in total length and weighs ca. 82 kg. Photograph by Herb Ellerbrock, Pittsburgh Zoo.

a clicker (sound producing device) as a bridge between the target and reward (R. Gibson, pers. comm.).

At the Pittsburgh Zoo, a study was initiated to test a dragon's spatial memory by examining whether dragons use proximal (nearby) or distal (far away) visual cues to remember the location of a food reward hidden in the lizard's exhibit. Preliminary results support the hypothesis that a dragon used proximal cues to remember the location of the food and additional experiments are underway to determine if a dragon can use distal cues in other circumstances (H. Ellerbrock, pers. comm.; Fig. 15).

Dragons will prove to be interesting subjects for future behavioral studies. What we have presented here is mostly anecdotal, but systematic studies to further examine the causes for these unexpected responses by dragons toward humans will be fruitful. But why are humans motivated to interact with dragons and why are these lizards often personalized? It seems as though large reptiles in zoos, especially dragons, are often given pet names but this rarely occurs with smaller ones. Retired NZP curator Dale Marcellini offered an interesting observation—perhaps the size and shape of dragons (and other reptiles such as crocodilians) which are somewhat similar to humans may be the main reason that humans pay more attention to these large reptiles and, as a consequence, may well initiate interactions with them. In an attempt to dominate all animals, some humans may specifically focus attention on large, possibly dangerous reptiles even when there are potential risks. In other cases, humans motivated to understand why reptiles operate the way they do may concentrate on dragons and other gargantuan reptiles. Detailed comparative studies with small reptiles and humans would be very enlightening.

There are examples of habituation ("tameness") in dragons in the wild, wild dragons brought into captivity, and those hatched in captivity. In a series of arresting photographs in her 1992 book called "Les Dragons de Komodo," Nicole Viloteau is interacting with two large wild dragons and one image shows her pulling out a gigantic dragon's tongue and kissing its tip.

In our combined experience working with living reptiles for nearly 90 years, no other species has interacted with humans like Komodo Dragons—these lizards are something special. Noted varanid biologist Eric Pianka put it this way: "Varanid lizards differ from other lizards in several ways. They have more aerobic capacity and greater metabolic scope, most varanids range over larger areas, and they are much more intelligent than other lizards. If you doubt this, go to a zoo that has a Komodo Dragon, make eye contact, and look into its eyes. You will be impressed with the way it looks back at you!"

Acknowledgments.—We dedicate this contribution to Gerard Visser, Curator of Fishes and Reptiles at the Rotterdam Zoo in the Netherlands. He is Co-Chair of the European Amphibian and Reptile Taxon Advisory Group and EEP-coordinator for Komodo Dragons. Gerard has had a positive impact throughout his professional life on studying and conserving dragons.

For various courtesies, we thank Kraig Adler, Eugène Bruins, Judith Bryja, Jessie Cohen, Falk Dathe, Dolly Ellerbrock, Herb Ellerbrock, Richard Gibson, Ruston Hartdegen, Lucian Heichler, Jennifer S. Holland, Bill Holmstrom, the late Marvin Jones, Jürgen Lange, Julie Maher, Jim Pether, Hans-Dieter Philippen, Christian Schmidt, Courtney Shaw, Frank Slavens, Brint Spencer, David Steele, and Gerard Visser. Kraig Adler, Judith Block, Judith Bryja, Ruston Hartdegen, Dale Marcellini, Gerard Visser, and Judy White reviewed an early draft of this manuscript. We have had fruitful discussions about the unique interactions between dragons and humans with John Arnett, Kurt Auffenberg, the late Walter Auffenberg, Gordon Burghardt, Vince Burke, David Chiszar, Claudio Ciofi, Colomba de La Panouse, the late Dennis King, Rob Lewis, Dale Marcellini, Eric Pianka, and John Romano.

Marvin L. Jones, retired registrar at the San Diego Zoo, died after suffering a massive heart attack on 4 April 2006. We consulted Marvin regularly about the history of dragons in zoos and aquariums during preparation of this manuscript, our last conversation occurring two days before his death. His knowledge of zoo history was encyclopedic and he was always willing to share his knowledge with his colleagues. He will be missed.

A Neotype for the Aldabra Tortoise, *Testudo gigantea* Schweigger, 1812

Statement of the problem: nomenclatural instability and confusion

Ever since their discovery by Europeans, giant tortoises of the western Indian Ocean have been at the center of taxonomic debates (Chambers 2004; Crumly 1988). Two clades are now recognized from this region (Arnold 1979): *Cylindraspis* spp., the extinct Mascarene tortoises, and *Aldabrachelys* from the Seychelles-Aldabra-Madagascar region (SAM). During nearly two centuries, no fewer than five generic names, and 13 epithets have been applied to the giant tortoises of SAM, with nearly 30 binomial combinations. Yet, recent genetic research indicates that despite this plethora of names there are but three distinguishable congeneric species in SAM: two fossil forms from Madagascar, and one living taxon, the Aldabra Tortoise (Austin et al. 2003; Karanth et al. 2005; Le et al. 2006; Palkovacs et al. 2002, 2003).

In the eye of this taxonomic tempest is the Aldabra Tortoise. Over the past two decades there has been growing confusion about which scientific name to apply to the giant tortoise that lives on Aldabra Atoll. During this period at least four generic names (*Aldabrachelys*, "*Dipsochelys*," *Geochelone*, and *Testudo*) and three epithets ("*dussumieri*," *elephantina*, and *gigantea*) have been used for this tortoise, with no fewer than six binomial combinations. This nomenclatural uncertainty affects not only the two fossil species on Madagascar, but also ongoing debates about giant tortoises from other islands in the Comores and Republic of Seychelles.

The contemporary surfeit of names for the Aldabra Tortoise stems from three issues: evolving opinions on the intergeneric relationships of land tortoises (Testudinidae), enhanced understanding of the taxonomic relationships of the nominal species that lives on Aldabra and Seychelles, and varying interpretations of how to deal with Schweigger's (1812) description of *Testudo gigantea*, for which there is no known type specimen.

With regard to the question of intergeneric relationships, ever since Loveridge and Williams' (1957:220 ff.) seminal study, the Linnean genus *Testudo* has generally been restricted to certain Old World, non-gigantic species, although as late as 1996 *Testudo gigantea* was still in use (e.g., Blaszkiewitz 1996). Loveridge and Williams (p. 225) proposed the subgenus *Aldabrachelys* for grouping the Aldabra tortoise and other closely related species within *Geochelone* Fitzinger, 1835. "*Dipsochelys*" was coined by Bour (1982) to replace *Aldabrachelys* (see below) as the genus for the Aldabra tortoise and its close relatives. Today the use of

Aldabrachelys (or "*Dipsochelys*") as a full generic name, instead of *Geochelone*, comes from the generally accepted conclusion that *Geochelone* (*s. lat.*) is not monophyletic but that its subgenera are monophyletic, although there are divergent views (see Austin et al. 2003:1415; Caccone et al. 1999:6; Crumly 1982:232; 1985:117; Crumly and Sánchez-Villagra 2004; Gaffney and Meylan 1988:210; Le et al. 2006; Meylan and Auffenberg 1987:74; Meylan and Sterrer 2000:68; Palkovacs et al. 2002:224).

From no later than 1877 until at least 1915 more than one species of giant tortoise was thought to live on Aldabra Atoll. Some of the better known works that reported various species to be sympatric on Aldabra, are Günther (1877:10): *elephantina*, *daudinii*, *hololissa*, and *ponderosa*; Boulenger (1889:167–169): *elephantina*, *daudinii*, *hololissa*, and *gigantea* (with *ponderosa* regarded as a junior synonym to *elephantina*); Rothschild (1897): *gigantea* and *daudini* [*sic*] (with *elephantina*, *hololissa*, and *ponderosa* regarded as junior synonyms of *gigantea*); and Rothschild (1915:425–427): *daudinii* and *elephantina* (with *gigantea* on some other island in Seychelles, and *hololissa* regarded as a junior synonym of *gigantea*, and *ponderosa* regarded as a hybrid of *elephantina* and *gigantea*).

Since 1950 most workers have agreed that just one species of giant tortoise, *gigantea*, lives on Aldabra and the Seychelles (e.g., Mertens and Wermuth 1955:377–378; Wermuth and Mertens 1961:204, 1977:84; Williams 1950:520, 551; 1952:557). However, in the last two decades there have been renewed claims that as many as four species of giant tortoise are living, or have lived, on Aldabra and Seychelles islands (e.g., Bour 1985a:54 ff, 1985b:60 ff., 1988:403; Gerlach 2004); these assertions have been contradicted by recent molecular genetic work (Austin et al. 2003; Karanth et al. 2005; Le et al. 2006; Palkovacs et al. 2002, 2003). Questions about intergeneric relationships and multiple species on Aldabra and Seychelles are beyond the scope of this paper. Here I evaluate only the nomenclatural status of Schweigger's (1812) name, *Testudo gigantea*.

Origin and early use of *Testudo gigantea* Schweigger

In 1812 *Testudo gigantea* was described by Schweigger in two places (page 327 and pages 362–363) in a monograph that was republished partially two years later (1814) (see Bour 1984a:162; Loveridge and Williams 1957:533). According to Schweigger (1812:327), the specimen upon which his description was based, from the royal collection of Lisbon, was examined in a museum in Paris (although not specifically stated, it was later assumed that this specimen was in the Muséum National d'Histoire Naturelle, Paris; see Bour 1984a:162; Crumly 1986:238; Pritchard 1986:522). It has been questioned if Schweigger "specially indicated" a type (Pritchard 1986:522; Rothschild 1915:430), for it was not customary at that time to do so. Nonetheless, the single specimen that Schweigger described is *ipso facto* the holotype, and it has been lost since at least the beginning of the 20th Century (Bour 1984a:162; Crumly 1986:238–239; Rothschild 1915:430). The "habitat" of *T. gigantea* was listed by Schweigger (1812) as "Brasilia." Certain other species described by Schweigger (1812), with erroneous localities, are recognized today (Crumly 1988:2; Pritchard 1986:531).

Between 1831 and 1881 numerous authors referred to *T. gigantea* in varying ways showing that there was considerable confusion about the taxonomy and zoogeography of giant tortoises, and this species in particular. *T. gigantea* was placed within the complex synonymy of *Testudo indica*, a species regarded by Gray (1831a:3, 1831b:9) as highly variable and found in many parts of the tropical world. Later, Gray (1844:5–6, 1855:5–6) placed *T. gigantea* within the synonymy of *Testudo indica*, but simultaneously listed it as "T. gigantea *Schweig.?*" (or "T. gigantea *Schweigger*?") in the synonymy of *Testudo tabulata*. Duméril and Bibron (1835:114, 120, 121, 123) and Duméril and Duméril (1851:5) recognized *T. gigantea* Schweigger as a separate species, of unknown "*patria*," but noted that it resembled closely *T. elephantina*, a species known from the region of the Mozambique Channel, including Aldabra and other islands. Gray (1869:171, 1870:7) made cautionary remarks about the risks of "determining species without the examination of all the parts of the animal, the skull as well as the thorax" raising the possibility that *gigantea*, as well as eight other nominal species of giant tortoise, might not be distinct species. Günther (1877:22 fn.) commented that *T. gigantea* may be the same species as *T. elephantina*, the latter known to live on Aldabra. Other interpretations during this fifty-year period include listing *Testudo gigantea* Schweigger under *Testudo tabulata* (Temminck and Schlegel 1835:69), a synonym of *Geochelone* (*Chelonoidis*) *denticulata* Linneaus 1766, from South America; and using the name *Scapia gigantea* Schweigger (Gray 1872:3, 8) as a new combination based upon a specimen of *Manouria emys* Schlegel and Müller, 1844, a species known from Southeast Asia.

Establishment of *Testudo gigantea* Schweigger as the Aldabra Tortoise

Hubrecht (1881:43) was the earliest author known to explicitly list the locality of *T. gigantea* Schweigger as Aldabra, "the chief dwelling place of the closely allied *Testudo elephantina*." He raised the question if these are distinct species, or "merely varieties of the same species." Boulenger, in his seminal catalogue (1889:168) listed the locality of *T. gigantea* Schweigger as Aldabra, along with *elephantina* and two other nominal species. He later (1894:305) referred to "the true *Testudo gigantea* of Schweigger" having earlier indicated that a fossil form from Madagascar is "most nearly allied to *Testudo gigantea* of the Aldabra Islands" (1893:581).

From 1881 until present, *T. gigantea* has been applied to the Aldabra Tortoise, with varying opinions on the number of other giant tortoise species on this atoll and elsewhere in the Seychelles islands. As many as seven different species have been recognized at one time from the Aldabra and Seychelles area (Rothschild 1915), and as many as four species were thought to occur on Aldabra by Günther (1877:10) and Boulenger (1889:167–169).

Rothschild (1897:407) recognized *T. gigantea* Schweigger as the oldest name for the Aldabra Tortoise, and established *elephantina* and *ponderosa* as subspecies, or "casual aberrations of *T. gigantea*;" he also recognized *T. daudini*. By 1950 *T. gigantea* was the only species of Indian Ocean giant tortoise mentioned in Williams' comparative study (1950:520, 536, 552), and later Williams (1952:557 fn.) drew attention to the fact that "*T. gigantea* is the oldest name" for the Aldabra Tortoise. In 1957 Loveridge and Williams (1957:225) designated *T. gigantea* Schweigger, as the type species of their new subgenus *Aldabrachelys*. Apart from the Aldabra Tortoise and the extinct Madagascar *grandidieri*, the only other species that they specifically included in their new subgenus

was *T. sumeiri* [*sic*], a name applied to a gigantic specimen of confused origin but generally thought to come from the Seychelles. Mertens and Wermuth (1955:377–378) and Wermuth and Mertens (1961:204) listed only one species from the Aldabra and Seychelles area: *Testudo gigantea* Schweigger, 1812, with three subspecies: *T. g. gigantea* from Mahé, *T. g. daudinii* from Aldabra's south island, and *T. g. elephantina* from Aldabra's north island. Other major taxonomic studies of testudines that continued to recognize *T. gigantea* as the only species from Aldabra include Auffenberg (1974:142) and Wermuth and Mertens (1977:84). Moreover, scores of authors in more than a hundred papers in a wide variety of scientific publications have also referred to the species of the Aldabra tortoise as *gigantea* (Gerlach 2001:23 tab. 1; Stimson, in Pritchard 1986:522).

Varying opinions on the established nomenclatural system

In 1982 Bour stated that Schweigger's type description of *T. gigantea* applied "*incontestablement*" [unquestionably] to an extinct Mascarene tortoise, now known as *Cylindraspis indica* (Schneider, 1783). Though acknowledging that *gigantea* had been used for decades, including by himself (e.g., Bour 1979:1225, 1980:543, 544, 1981:120), Bour concluded that the name could not be applied to the Aldabra Tortoise and decided it was a junior synonym of *T. indica* Schneider, 1783. He then revived Duméril and Bibron's (1835) name, *T. elephantina* for the Aldabra Tortoise. Bour further concluded that *Aldabrachelys* (Loveridge and Williams 1957: 225 "Type species: *Testudo gigantea* Schweigger") was not available for the Aldabra Tortoise, but a junior synonym of *Cylindraspis* Fitzinger, 1835. On the basis of these decisions, Bour erected a new genus "*Dipsochelys*" for the giant tortoises of the Seychelles-Aldabra-Madagascar region. He later published more extensive arguments along these same lines (Bour 1984a, b); in all cases his evidence was based solely on Schweigger's (1812) description.

Pritchard (1986) agreed with Bour that Schweigger had not described an Aldabra Tortoise. However, he concluded that the 1812 description applied to the South American *Geochelone* (*Chelonoidis*) *denticulata*. Like Bour, Pritchard developed intricate arguments for reinterpreting the original description. His strongest point was an assertion that "there is persuasive circumstantial evidence that the specimen indeed came from Brazil" (1986:528). While his reinterpretation is compelling, a careful reading of Pritchard's arguments reveals that they are replete with qualifiers and caveats (for example in regard to the reliability of type localities from that era, Schweigger's two recognizable descriptions of *denticulata* listed the species as native to Virginia [Crumly 1988:2; Pritchard 1986:531]; see Rasmussen and Prys-Jones [2003] for a detailed discussion on the complexities of interpreting locality data from 19th Century ornithological specimens). Moreover, Pritchard stated that Schweigger did not designate type specimens, indicating that no type specimen for *T. gigantea* will ever be located. While Pritchard agreed with Bour that *gigantea* should be replaced by *elephantina*, he argued that *Aldabrachelys* should be maintained as per his interpretation of the rules and recommendations of the International Commission of Zoological Nomenclature (ICZN). He admitted that "invalidation of the familiar epithet *gigantea* represents a rather profound upheaval," reporting that this name was well established during the past fifty years of publications (1986:522, 531).

Crumly (1986) adopted a conservative approach to these nomenclatural dilemmas, explaining that Schweigger's (1812) description was not easy to interpret, and observing that *gigantea* was the established name for the Aldabra Tortoise. Given that the priority of the ICZN is to maintain stability and universality, he saw no reason to cause instability in a system that was established and widely used by a diversity of researchers and publications, and he reasoned that both *gigantea* and *Aldabrachelys* are valid and should be retained.

In their taxonomic review published for the Association of Systematics Collections, King and Burke (1989:70) decided to follow Pritchard (1986), as did Broadley and Howell (1991:8) in their checklist and synoptic keys. However, numerous specialists in chelonian systematics have continued to use *gigantea* for the Aldabra Tortoise, employing either *Geochelone* or *Aldabrachelys* as the generic name (e.g., Austin and Arnold 2001:2515; Austin et al. 2002:281, 2003:1417; Crumly 1988:2; Crumly and Sánchez-Villagra 2004:136, tab. 2; Ernst and Barbour 1989:250; Iverson 1992:249; Meylan and Auffenberg 1986:303, 1987:76; Meylan and Sterrer 2000:52; Zug et al. 2001:44 ff.).

A major proponent of name change for the Aldabra Tortoise and rejection of the established nomenclatural system has been Gerlach (e.g., Gerlach 1997, 2001, 2004; Gerlach and Canning 1995; see Frazier 2006 for details), who argued for the use of "*Dipsochelys dussumieri*" for the Aldabra Tortoise, thereby rejecting Bour (1984a:171 fn. 1, 1984b:282) and Pritchard's (1986:532) arguments that Gray's (1831) *T. dussumieri* is a *nomen oblitum*. In fact, Gray (1831a:3, 1831b:9, 1844:5, 1855:6), as well as Temminck and Schlegel (1835:75), clearly used "*Test. dussumieri*" only as a synonym for *Testudo indica* Schneider, 1783; hence, *T. dussumieri* is an unavailable name (ICZN Art. 11.6; Frazier, *in prep.*). Gerlach (2001:23 tab. 1) has presented a summary of names used in tortoise publications that clearly shows that *gigantea* is the established name for the Aldabra Tortoise.

Bour, in proposing the invalidation of *gigantea*, admitted to being "embarrassed to run counter to an apparently satisfying system" (1984b:281), but it is unclear what name he now prefers for the Aldabra Tortoise. Recently he has coauthored publications that have used *Aldabrachelys gigantea* (Austin et al. 2002, 2003). Yet, he has also been a coauthor of a paper in which "*Dipsochelys dussumieri*" was used for the Aldabra Tortoise (Gerlach and Bour 2003). In his review of Gerlach's (2004) popular book, Bour (2004) wrote: "[t]he author [Gerlach] has chosen to use a generic name, *Dipsochelys*, and a specific name, *dussumieri*, which are not absolutely unequivocal."

Possible disadvantages from the continued use of *Testudo gigantea* Schweigger

The only possible problem that has been mentioned for the continued use of *gigantea* for the Aldabra Tortoise is Pritchard's remark (1986:532) that the same species name was used by Grandidier (1868a, b) for an extinct giant tortoise from Madagascar, *Emys gigantea*. However, this junior homonym of *T. gigantea* Schweigger was purposely replaced by Vaillant (1885:876) with *T. grandidieri* (see also Boulenger 1894:305). Hence, *Emys gigantea* has long since been supplanted by *T. grandidieri*, with widespread and continuous use, including by Pritchard himself

(Pritchard and Trebbau 1984:198). The only way that this homonym could cause a problem would be to invalidate Vaillant's established designation and try to supplant it with Grandidier's long disused name—a proposition that would only cause more chaos and instability and contravene ICZN Article 59.1 (1999).

Summary of the contemporary situation regarding *Testudo gigantea* Schweigger

The above discussion clearly shows that there is not only general instability and chaos regarding the valid name of the Aldabra Tortoise, but the major proponents (Bour 1982, 1984a, b; Gerlach 2001; Pritchard 1986) for "invalidating" *gigantea* have admitted that this action causes upheaval in an established nomenclatural system, thereby negating the ICZN objectives of stability, priority, and universality. Other specialists of chelonian taxonomy and systematics have chosen to reject the claim that Schweigger's (1812) *T. gigantea* is not valid (see above). As mentioned earlier, Rothschild (1915) and Bour (1982) reported that the type specimen is lost. Although other workers (e.g., Arnold, Gerlach, Pritchard) have examined type material of giant tortoises in the Muséum National d'Histoire Naturelle, Paris, with special attention to old types, there is no evidence that Schweigger's (1812) type is extant. Consequently, while scholars may continue to reinterpret Schweigger's (1812) description, there can be no unequivocal determination, for this type specimen is lost.

Designation of the neotype for *Testudo gigantea* Schweigger, 1812

To clarify the situation and stabilize the name for the Aldabra Tortoise, I designate USNM 269962, an adult male from Dune Patates, South Island, Aldabra Atoll, Republic of Seychelles, as the neotype of *Testudo gigantea* Schweigger, 1812. This specimen at the National Museum of Natural History, Smithsonian Institution, consists of a skull, mandible, articulated carapace and plastron, scutes (most of which are attached to the shell), postcranial skeleton, and fragments of skin. Skull measurements (mm) are: basicranial length = 110; maximum length = 123; maximum width = 82.9. Shell measurements (cm) are: straight carapace length = 82.4, curved carapace length = 116.2; straight width of 3rd vertebral = 28.0, curved width of 3rd vertebral = 30.1; and plastron length = 65.0 (see Grubb [1971:330] for a description of methods for measuring Aldabra Tortoise shells). There is a conspicuous nuchal scute; and the fourth vertebral has an epoxy-filled circle where a titanium disk was once attached (see Gaymer 1973). This neotype is a specimen of the nominal species *Testudo gigantea* Schweigger, which has recently been defined and diagnosed thoroughly as *Aldabrachelys gigantea* by Arnold (1979:138), as *Geochelone gigantea* by Crumly (1982:218 ff., 1985:124) and Crumly and Sánchez-Villagra (2004:Table 2. ff.), and as "*Dipsochelys elephantina*" by Bour (1994:19–25, 93 ff.). As Loveridge and Williams (1957:225) noted when erecting the subgenus *Aldabrachelys*, this taxon is characterized by having the external naris higher than wide.

The status of *Aldabrachelys* Loveridge and Williams, 1957

As summarized above, Bour (1982:117, 1984a:170, 1984b:282) stated that Loveridge and Williams' (1957:225) subgeneric name *Aldabrachelys* is a junior synonym for *Cylindraspis* Fitzinger, 1835, and is thus not valid for the Aldabra Tortoise. Nonetheless, various authors have reasoned that without a ruling by the ICZN, *Aldabrachelys* continues to be available for the Aldabra Tortoise (Crumly 1986:240; King and Burke 1989:70; Meylan and Auffenberg 1987:74; Pritchard 1986:532). Bour (1994:136–137) contended that these authors were in error, and he stated that he will continue to use "*Dipsochelys*" for the generic name of the Aldabra Tortoise until a "hypothetical decision" is taken by the Commission. It is unclear if he ever submitted a proposal to the Commission, and as Bour (1994:137) admitted, the Commission has not offered an opinion on the status of the purported misidentified type specimen of *Aldabrachelys*. Hence, Loveridge and Williams' (1957) name continues to be available for the Aldabra Tortoise and closely allied species. In any case, *Dipsochelys* Bour, 1982, is a subjective junior synonym and not a valid name for the Aldabra Tortoise. Moreover, the designation of a neotype for the type species (*Testudo gigantea* Schweigger) of the genus *Aldabrachelys* Loveridge and Williams (1957) removes the nomenclatural confusion associated with the generic name of the Aldabra Tortoise. *Aldabrachelys* stands as the valid generic name for *Aldabrachelys gigantea* and other closely allied species (*A. abrupta*, *A. grandidieri*, and *A. laetoliensis*) whenever these species are regarded as generically distinct from other taxa of giant tortoises.

Acknowledgments.—Valuable assistance with bibliographic and collections material and citations was provided by K. Adler, A. Bauer, P. Lasker, L. Overstreet, D. Steere, and A. Wynn. C. Crumly, P. Meylan, R. Redick, G. Zug, and M. Yánez Quezada made valuable comments on earlier drafts, and R. Espinoza provided editorial help. During the preparation of this neotype designation R. McDiarmid gave invaluable collaboration, and the patient, unstinting advice and nomenclatural wisdom of J. Savage has been fundamental.

Histology and Histochemistry of Caudal Courtship Glands in Three Arkansas Plethodontid Salamanders

MICHELLE N. MARY
and
STANLEY E. TRAUTH
Department of Biological Sciences, Arkansas State University
P.O. Box 599, State University, Arkansas 72467, USA
e-mail (MNM): michellenmary@yahoo.com
e-mail (SET): strauth@astate.edu

Breeding behavior in plethodontid salamanders is comprised of several stages that employ tactile, chemical, and possibly visual stimulation (Verrell 1997). Certain integumentary glands called caudal courtship glands, located at the dorsal base of the tail in some male plethodontid salamanders, presumably produce pheromones and are of special interest concerning courtship and mating behavior (Sever 1989). Caudal courtship glands were first reported and histologically described in plethodontids by Noble (1929), who called them "hedonic" glands. Arnold (1977) later renamed them "courtship" glands and suggested these glands be referred to by their anatomical position (hence the name "caudal" courtship glands; Staub and Paladin 1997). Courtship glands may play a pivotal role in reproduction by pheromonally influencing female receptivity during mating (Sever 2003), and thereby influencing individual mating success.

Caudal courtship glands produce secretions during the breeding season (Sever 1989, 2003). During the mating season some male plethodontids (e.g., *Plethodon jacksoni* = *Plethodon wehrlei*—Newman 1954; *Eurycea multiplicata*—Noble 1929) exhibit an elevated ridge or protuberance at the dorsal base of the tail within which caudal courtship glands have been found (Hamlett et al. 1998; Sever 1989; Trauth et al. 1993). The secretions produced by these glands are thought to aid in eliciting the "tail-straddling walk," which is a courtship component unique to plethodontids (Arnold 1977). During this walk the female places her snout directly above the glands on the tail base of the male. Her nasolabial grooves are believed to transfer chemicals from these glands to her vomeronasal organs (Houck and Sever 1994) where pheromonal stimulation presumably maintains the female's interest while the male deposits a spermatophore on the substrate. The female then may pick up the spermatophore with her cloacal lips, essentially completing the tail-straddling walk. Since spermatophore deposition is dependent upon the female being in the tail-straddling position (Houck and Reagan 1990) and because pheromonal secretions from the caudal courtship glands presumably increase the likelihood that the female will remain in this position, these glands would increase success in male insemination of a female. Although sexual dimorphism and hypertrophy during the breeding season provide compelling evidence of a courtship function for these glands (Sever 2003), functional tests have not been performed.

Caudal courtship glands are known in *Desmognathus, Eurycea*, and *Plethodon* (Sever 2003). Histological evidence also exists for several species of *Eurycea* (Hamlett et al. 1998; Noble 1929; Sever

TABLE 1. Staining properties of various epidermal glands of *Plethodon albagula*, *Desmognathus brimleyorum*, and *Plethodon ouachitae*. Negative reaction (-), weak positive reaction (+), strong positive reaction (+++).

Species	Gland type	H&E	Pollak trichrome	Alcian blue	PAS	Secretion type

1985, 1989; Trauth et al. 1993), *Plethodon cinereus* (Houck and Sever 1994; Noble 1929), *Plethodon jordani* (Noble 1929) and several desmognathines (e.g., *Desmognathus phoca* = *Desmognathus monticola*; *Desmognathus fuscus fuscus* = *Desmognathus auriculatus*; *Desmognathus fuscus carolinensis* = *Desmognathus ochrophaeus*—see Noble 1929). Herein, we report the presence of these glands in three additional species of salamanders in the two plethodontid subfamilies: Desmognathinae (*Desmognathus brimleyorum*, the Ouachita Dusky Salamander) and Plethodontinae (*Plethodon albagula*, the Western Slimy Salamander, and *P. ouachitae*, the Rich Mountain Salamander). In addition, our study provides the first histological detail describing caudal courtship glands in a desmognathine salamander.

Methods.—Male specimens were collected from Polk, Montgomery, Crawford, Newton, Logan, and Pike counties in Arkansas (Appendix 1; *P. albagula*, N = 5; *P. ouachitae*, N = 2; *D. brimleyorum*, N = 6). They are deposited in the Arkansas State University Herpetological Museum. The majority of voucher specimens were collected during the spring months (from Mar–May; N = 11). Early spring appears to be the optimal breeding season for these species (Taylor et al. 1990; Trauth et al. 1990), although little is actually known about the mating season in Arkansas. Specimens collected during this period were examined because caudal courtship glands are known to hypertrophy during the breeding season in other species (Sever 1989), thus indicating that they may serve some function related to mating. For comparison, some animals were collected from the non-reproductive season (N = 2). The snout–vent length (SVL) of each specimen was measured from the tip of the snout to the anterior margin of the vent.

Histological examination was performed using routine histological methods (Presnell and Schreibman 1997). Skin was excised from the dorsal base of the tail of preserved specimens and compared to patches of skin excised from the trunk region just

Granular and mucous glands present in the dorsal trunk region of *Desmognathus brimleyorum* stained with alcian blue; scale bar = 50 µm. D. Granular and mucous glands present in the dorsal trunk region of *Plethodon ouachitae* stained with alcian blue; scale bar = 100 µm. Adipose tissue (AD), caudal courtship glands (CC), epidermis (EP), granular glands (GG), mucous glands (MG), muscle (MU).

anterior to the hind legs. Tissue samples were dehydrated in a graded series of ethanol solutions, cleared in xylene, infiltrated and embedded in paraffin, and serially sectioned into ribbons 8 µm thick. Serial ribbons were mounted on glass slides using Haupt's adhesive.

Tissues were stained or treated with four histological stains: hematoxylin and eosin (H & E), alcian blue 8GX (pH 2.5), Pollak trichrome, and periodic acid-Schiff reagent (PAS). General cytology was revealed by using H & E, and alcian blue indicated the presence of carboxylated glycosaminoglycans. Pollak trichrome revealed connective tissue and mucins (common in glandular secretions) and was expected to stain elastin red, fibrin and calcium purple, collagen and mucus blue green. Neutral carbohydrates, mucopolysaccharides, mucoproteins, glycoproteins, and other carbohydrate-protein substances were reveal by PAS (Presnell and Schreibman 1997). Collectively, these stains and reactions revealed the presence of caudal courtship glands and allowed for differentiation among all glands present in the epidermis (caudal courtship, granular, and mucous glands; see Sever 1989). Tissues were examined and photographed using a compound light microscope at 100× magnification.

Caudal courtship glands are, in part, defined by their staining properties. They are known to have an eosinophilic reaction with H&E, a negative reaction with alcian blue, a positive reaction with PAS, and mixed reactions (more than one color evident) with Pollak trichrome (Hamlett et al. 1998; Sever 1989; Trauth et al. 1993). These glands are also defined by their anatomical location on the dorsal tail base.

Results.—Plethodon albagula (mean SVL = 71 ± 0.96 mm; range 62–72 mm), *P. ouachitae* (mean SVL = 58 ± 2.8 mm; range 56–60 mm), and *D. brimleyorum* (mean SVL = 78 ± 6.9 mm; range 76–89 mm) possessed caudal courtship glands in the skin at the dorsal base of their tails. No male specimen examined in this study lacked caudal courtship glands. These glands contain serous secretions and differ in staining properties (Table 1) from granular and mucous glands also located in this region (Fig. 1).

The epithelium of caudal courtship glands in *P. albagula, P. ouachitae*, and *D. brimleyorum* was simple columnar, and nuclei were arranged basally in each gland cell (Figs.1A, 1C, and 2A). Epithelia of mucous and granular glands were modified low simple columnar that almost appeared squamous-like (Figs. 1A, 1D, and 2A).

Caudal courtship glands of *P. albagula* (Fig. 1B), *P. ouachitae* (Fig. 1D) and *D. brimleyorum* exhibited secretions with no reaction to alcian blue and a slightly positive reaction to PAS (Table 1). Caudal courtship glands of *P. albagula* produced secretions that were slightly basophilic with H & E. In *P. ouachitae* and *D. brimleyorum* (Fig. 2A), secretions of caudal courtship glands appeared slightly eosinophilic with H & E. With Pollak trichrome, secretions of *P. albagula, P. ouachitae*, and *D. brimelyorum* stained dark red (*D. brimleyorum* secretions often additionally contained a blue-green component), and epithelia stained blue-green with dark red nuclei (Fig. 1A,1C).

During the breeding season, caudal courtship glands in the tail base region of *P. ouachitae* varied in shape, including triangular, barrel-shaped, or spherical configurations, presumably due to

squeezing from the surrounding hypertrophied granular glands (Figs. 1C and 1D). Caudal courtship glands were spherical in *D. brimleyorum* (Fig. 2A) and spherical or ovoid in *P. albagula* (Figs. 1A and 1B). There was no consistent difference in shape between pre-secretory, secretory, and post-secretory stages.

Granular glands, mucous glands, and caudal courtship glands of specimens of *P. albagula* collected outside the breeding season appeared extremely small relative to their size in specimens examined within the breeding season; moreover, they appeared to be fewer in overall number (Fig. 2B). Courtship glands were rarely observed or were absent in sections of the skin taken from the trunk region of the body (Figs. 2C and 2D).

Discussion.—Although no female plethodontids were examined in this study, we conclude that the glands examined are caudal courtship glands based on staining property similarities between the glands in the present study and glands described by Sever (1989), Trauth et al. (1993), and Hamlett et al. (1998). We predict that these glands will be absent in female plethodontids. The absence or extreme reduction in caudal courtship glands size in specimens collected outside of the breeding season compared with those from specimens collected within the breeding season also supports their classification as courtship glands. The absence of these glands in the trunk region provides additional evidence that they may play a role in the tail-straddling walk stage of courtship.

Staining of caudal courtship glands in *P. albagula* differed from *Eurycea longicauda melanopleura* and *E. lucifuga* in that Trauth et al. (1993) and Hamlett et al. (1998) found the latter two species to appear eosinophilic with H & E. Our study revealed them as basophilic. Caudal courtship gland secretions in *P. ouachitae* and *D. brimleyorum* stained similarly to those in *E. l. melanopleura* and *E. lucifuga* (eosinophilic). Staining properties of caudal courtship glands in *P. albagula, P. ouachitae,* and *D. brimleyorum,* agreed with those in *E. lucifuga* and *E. l. melanopleura*, when PAS, alcian blue, and Pollak trichrome were employed.

All staining properties of glands in *D. brimleyorum* and *P. ouachitae* match those found by Sever (1989) in the *Eurycea bislineata* complex. He reported that caudal courtship glands are eosinophilic. Our results for *P. albagula* differ; a basophilic reaction is indicated. Agreement of staining properties resulting from PAS and alcian blue in our study with Sever (1989) suggests that secretions of caudal courtship glands *in P. albagula, P. ouachitae,* and *D. brimelyorum* are also likely mucoproteins.

Staining with Pollak trichrome indicated the possible presence of elastin (red), fibrin and calcium (purple), and collagen and mucus (blue-green) in caudal courtship glands (Presnell and Schreibman 1997). Positive reactions of caudal courtship glands with PAS and negative reactions of these glands with alcian blue may indicate the presence of a neutral carbohydrate (Hecker et al. 2003).

Courtship glands can occur in areas other than the dorsal tail base (Noble 1929; Thurow 1968), although they are normally concentrated at the tail base. In *D. brimleyorum*, the large caudal courtship glands occupied such an overall high volume during the breeding season that they displaced the adjacent mucous glands in the tail base region.

Our study has revealed the existence of caudal courtship glands in three additional plethodontid species and includes the first detailed histological description of these glands in a desmognathine salamander. Knowledge of the presence of caudal courtship glands is useful because pheromones produced by these glands probably increase female receptivity and, therefore, male mating success. Although overall understanding of the role of glandular secretions and their relationship to salamander behavior in plethodontid salamanders remains insufficient, female receptivity and the probability of insemination are known to increase markedly due to the effects of courtship glands (e.g., mental glands; Houck and Reagan 1990). Further investigations of caudal courtship glands will undoubtedly shed more light on this remarkable method of sexual communication in salamanders.

Acknowledgments.—We thank D. M. Sever and M. L. McCallum for their critical comments regarding earlier versions of this manuscript.

The Panamanian Golden Frog, *Atelopus zeteki* Dunn (Anura: Bufonidae), is a taxon of concern endemic to the Coclé and Panamá Provinces of Panama (Dunn 1933; Savage 1972), principally inhabiting lowland rainforest (Savage 1972) on the Pacific cordilleran slope. Bufonidae are among four families of amphibians containing more "rapidly declining" species than the average (Stuart et al. 2004), and of 34 species of amphibians which have gone extinct since 1500 (Stuart et al. 2004), three were in the genus *Atelopus* (IUCN et al. 2004). In addition, of 77 described species of *Atelopus* (Frost 2004), 61 (82%) are listed as Critically Endangered (IUCN et al. 2004), and it has been suggested that this is the first example of a species-rich lineage being so uniformly imperiled (Lötters et al. 2004). In particular, *Atelopus zeteki* is listed as Critically Endangered (IUCN et al. 2004) and given the highest level of protection by the Convention on International Trade in Endangered Species (CITES I). Development of conservation strategies and long-term monitoring programs for threatened species is contingent upon understanding species' life histories. As basic biological and ecological information is lacking for many *Atelopus* species, collection of such data may be crucial for conservation efforts.

Relatively little is known about the reproductive ecology of *Atelopus* frogs (Lötters 1996). While breeding phenology usually varies somewhat among species and populations depending upon local climatic conditions, limited data suggest that *Atelopus* breeding generally occurs at the beginning of the dry season (Lötters 1996, Savage 2002). *Atelopus* oviposit in cryptic locations, attaching their eggs to the undersides of rocks in swiftly flowing streams generally during periods of low water flow (Savage 1972, Lötters 1996). Previous descriptions of egg-laying and clutch characteristics come principally from captive or dissected animals. The few reported field observations of egg masses or oviposition sites provide limited data on clutch sizes, ovum diameter, and/or oviposition site characteristics in *A. flavescens* (Lescure 1981) and *A. franciscus* (Boistel et al. 2005) from French Guyana, and *A. muisca* (Rueda-Almonacid and Hoyos 1991) from Colombia. To our knowledge, no published information from the field or laboratory exists on the reproductive ecology of *A. zeteki.* Our objectives were to describe the clutches and oviposition sites of *A. zeteki* and compare their reproductive ecology with that of other *Atelopus* species.

Materials and Methods.—In 10–16 December 2004 and 8–15 December 2005, we conducted surveys for *Atelopus zeteki* in Panamá Province, Panama, in a small stream ca. 5–15 m in width with steep rocky slopes. We searched for *A. zeteki* egg masses by overturning rocky substrates and submerged woody debris and examining accumulations of leaf litter within the stream channel along a 200 m reach. These searches were conducted in conjunction with surveys for adult *A. zeteki* along the stream margins and on exposed rocks and small islands within the stream. All frogs were marked by toe-clipping. When clutches were found, we counted the number of eggs per clutch and measured the diameters of at least 20 eggs, randomly chosen, from each of three clutches. Embryo developmental stages were estimated (Gosner 1960). To characterize the microhabitat at oviposition sites, we measured overstory canopy closure using a concave spherical densiometer (only in 2005), size of substrate (Platts et al. 1983) to which an egg mass was attached, predominant size of surrounding substrate (visually estimated within a 1 m^2 area centered on the oviposition substrate), water depth at the location of the clutch (only in 2004), distance of oviposition substrate to wetted edge, wetted width of stream at each oviposition site, stream velocity (m/s) near each egg mass, and instream habitat type (e.g., pool or riffle, Platts et al. 1983). Stream velocity at oviposition sites was estimated by determining the time it took for a floating object to travel a 1 m stream segment centered on the location of an egg mass. Velocity was calculated as the distance traveled divided by the time elapsed. In addition, we measured the distance between clutches within each year. In 2004, we measured general habitat conditions for five of the variables along the stream reach and

UROTHECA DECIPIENS (Collared Glass-tailed Snake). **DIET**. *Urotheca decipiens* is a small, diurnal, terrestrial snake that is reported to consume amphibians and small lizards (Solorzano 2004. Snakes of Costa Rica. Instituto Nacional de Biodiversidad, Santo Domingo de Heredia, Costa Rica. 791 pp.). At 2000 h on 22 September 2005 we found an adult female *U. decipiens* (240 mm SVL; 37 mm tail length; 6.8 g) moving through the leaf litter after dark in Omar Torrijos National Park (Cocle Province, Panama). A portion of the tail was missing, presumably lost as part of the antipredatory defense that is typical of the genus (Savage 2002. The Reptiles and Amphibians of Costa Rica. Univ. Chicago Press, Chicago, Illinois. 934 pp.). After collection the snake regurgitated the head and neck of a small *Sphaerodactylus* sp. This is the first report of *Sphaerodactylus* in the diet of *U. decipiens*, as well as the first report of *U. decipiens* in Cocle Province and Central Panama. In addition, our observation of the active snake at night suggests *U. decipiens* may not be entirely diurnal. The snake and its gut contents were deposited in the Circulo Herpetologico de Panama (*U. decipiens* CH 5975; *Sphaerodactylus* sp. CH 5976).

ELEUTHERODACTYLUS SYMINGTONI (NCN). CUBA: PINAR DEL RÍO: Sierra de la Güira, small cave 2 km SW of Los Bermejales (22°40'5.9"N, 83°26'30.5"W). 14 December 2003. A. Rodríguez. Instituto de Ecología y Sistemática, Colección Zoológica de la Academia de Ciencias de Cuba (CZACC14. 12798). Sierra de la Güira, Los Bermejales, Cueva de Bartolo (22°49'5.9"N, 83°25'53.0"W). 14 December 2003. O. Jiménez and M. Condis. CZACC 14. 12799. Both verified by L. V. Moreno. First records for Sierra de la Güira, and a range extension of 15 km SW from the nearest known locality at Pan de Guajaibón, and only the seventh known locality for this species on Cuba (Schwartz 1957. Proc. Biol. Soc. Washington 70:209–212; Estrada 1989. Rev. Biol. 3:155–165). Both frogs were found during daylight inside caves. The records could influence future assessments on the conservation of this species, which was considered critically endangered by Rodriguez et al. (1999. *In* Perez et al. [eds.], Conservation Breeding Specialist Group (SSC/IUCN). Report of Conservation Assessment and Management Plan Workshop for Selected Cuban Species: SBSG. Apple Valley, Minnesota).

Submitted by **ARIEL RODRÍGUEZ** and **ROBERTO ALONSO**, Instituto de Ecología y Sistemática, Carr. De Varona, Km 3 1/2, Capdevila, Boyeros. AP 8029, CP 10800, Ciudad de la Habana, Cuba; e-mail: ariel@ecologia.cu.

GLYPHOGLOSSUS MOLOSSUS (Blunt-headed Burrowing Frog). THAILAND: PHETCHABURI PROVINCE: Ban Lat District: Huay Luk Subdistrict: Poo Toom Mountain, near Ban Poo Toom. 21 January 2006. O.S.G. Pauwels. Thailand Natural History Museum, Pathum Thani (THNHM 09966). Verified by Wichase Khonsue (Chulalongkorn University, Bangkok). A single adult specimen caught at 1515 h in a rock crevice filled with water and tree leaves on a hilltop in dry dipterocarp forest. It was found

in syntopy with an adult *Bufo melanostictus*. First provincial record and southwesternmost record for the genus. The closest Thai record is from Ratchaburi Province, to the north, without a precise locality (Taylor 1962. Univ. Kansas Sci. Bull. 43[8]:265–599; Nutphund 2001. Amphibians of Thailand. Amarin Printing and Publishing Public Co., Ltd., Bangkok; Chan-ard 2003. A Photographic Guide to Amphibians in Thailand [in Thai]. Darnsutha Press, Bangkok; Nabhitabhata et al. "2000" [2004]. Checklist of Amphibians and Reptiles in Thailand. Office of Environmental Policy and Planning, Bangkok, Biodiversity Series, vol. 9).

We thank Tanya Chan-ard (National Science Museum, Pathum Thani) and Peter Paul van Dijk (Conservation International, Washington, D.C.) for information and Thongchana Chimsunchart (Ban Lat) for assistance in the field.

PSEUDIS CARDOSOI (NCN). BRAZIL: SANTA CATARINA: Municipality of Lebon Régis, Serra da Esperança (26°51'28"S, 50°41'13"W, 1125 m elev.). 25 October 2005. R. Lingnau. Museu de Ciências e Tecnologia da Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil (MCP 8607 male, collected at night, vocalizing at a permanent pond). Verified by A. Kwet. The species occurs in the southern regions of the Serra Geral, and is known from several localities in Rio Grande do Sul State (Kwet 2000. Amphibia-Reptilia 21:39–55). It is assumed that the species also occurs in Santa Catarina, but no voucher is preserved in collections (Kwet, *op. cit.*). First vouchered record from the Santa Catarina State, extending the known range ca. 150 km N airline from the Municipality of Vacaria, in Rio Grande do Sul State.

Submitted by **RODRIGO LINGNAU** (e-mail: rodrigolingnau@yahoo.com.br) and **MARCOS DI-BERNARDO**, Laboratório de Herpetologia, Museu de Ciências e Tecnologia and Faculdade de Biociências, Pontifícia Universidade Católica do Rio

Grande do Sul. Av. Ipiranga, 6681, 90619-900 Porto Alegre, RS, Brazil.

TESTUDINES

APALONE SPINIFERA PALLIDA (Pallid Spiny Softshell). USA: ILLINOIS: JERSEY CO.: Side channel of the Mississippi River, west of the confluence of Piasa Creek and the Mississippi River side channel at approximate River Mile 209 (UTM: zone 15 E 734629m, N 4312837m, NAD27CONUS). 24 October 2005. Collected by John K. Tucker, James T. Lamer, and Chad R. Dolan, Illinois Natural History Survey. INHS 19855. Verified by Chris Phillips, INHS. Specimen is a first county and state record (Phillips et al. 1999. Field Guide to Amphibians and Reptiles of Illinois.) Specimen was live-captured in a fyke net along with 32 Eastern Spiny Softshell Turtles (*Apalone spinifera spinifera*) after a four-day set. This is a significant range extension (~1000 km) for this subspecies as it is typically found in western Louisiana to southern Oklahoma, and most of the northern and eastern parts of Texas (Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Inst. Press, Washington and London. 578 pp.). It is the first specimen reported from Illinois, and may be a released captive. Its true origin and means of arriving in Illinois is uncertain. This specimen is of significance because of its potential to interbreed with *A. s. spinifera*, the native subspecies. Shell dimensions and mass for this male specimen, recorded while still alive, are as follows: carapace length = 165 mm, carapace width = 134 mm, carapace height = 49 mm, plastron length = 119 mm, mass = 510 g.

Submitted by **JAMES T. LAMER, JOHN K. TUCKER,** and **CHAD R. DOLAN,** Illinois Natural History Survey, 8450 Montclair Ave., Brighton, Illinois 62012, USA.

KINOSTERNON LEUCOSTOMUM (White-lipped Mud Turtle, Tortuga Amarilla). HONDURAS: CAYOS COCHINOS ARCHIPELAGO: Bay Island Province: Cayo Cochino Pequeño, SE side of island near a freshwater outlet (15°56'59"N, 86°29'59"W, datum: WGS84), 1 m elev. 25 July 2004. S. M. Boback. Verified by Andy Holycross. Photo vouchers, of complete empty shell with intact scutes, deposited in Arizona State University Museum (ASU HP-00049–00050). First record for Cayo Cochino Pequeño (McCranie et al. 2005. Amphibians and Reptiles of the Bay Islands and Cayos Cochinos, Honduras. Bibliomania, Salt Lake City).

We thank the Honduran Coral Reef Foundation and Operation Wallacea for supporting our research in the Cayos Cochinos.

TERRAPENE CAROLINA TRIUNGUIS (Three-toed Box Turtle). USA: TEXAS: KLEBERG CO.: Hwy 77 south frontage road, ca. 0.2 km S of jct. with General Cavazos Blvd (27°29.432'N, 97°50.882'W). 14 May 2004. Collected by Lucy E. Arispe. Verified by Travis J. LaDuc. Texas Natural History Collections (TNHC 63215). New county record, extends range south two counties (Dixon 2000. Amphibians and Reptiles of Texas, 2nd ed. Texas A&M Univ. Press, College Station. 421 pp.).

Submitted by **RANDY L. POWELL** and **LUCY E. ARISPE**, Natural Toxins Research Center, MSC 158, Texas A&M University, Kingsville, Texas 78363, USA; e-mail: randy.powell@tamuk.edu.

TERRAPENE NELSONI NELSONI (Southern Spotted Box Turtle). MÉXICO: JALISCO: Municipality of Guachinango, ca. 30 km WSW from Ameca, 1250 m elev. 18 June 1999. Omar Montes-Ontiveros. Verified by John Iverson. Bosque Tropical Herpetological Collection, Guadalajara, México (BT, M-018). First record for Jalisco and a 230 km range extension SSE of the nearest record at Pedro Pablo, Nayarit (Milstead and Tinkle 1967. Copeia 1967:180–187).

Submitted by **OMAR MONTES-ONTIVEROS,** Ornitorinco S.P.R. de R. L., Alliot # 3990, C.P. 45070, Zapopan, Jalisco, México (e-mail: ornitorrincomex1@hotmail.com); and **PAULINO PONCE-CAMPOS**, Bosque Tropical, A.C., Apartado Postal 5-515, Guadalajara, Jalisco 45042, México (e-mail: poncecp@hotmail.com).

TRACHEMYS SCRIPTA ELEGANS (Red-eared Slider). USA: FLORIDA: LEON CO.:, multiple localities in the vicinity of Tallahassee, first county records as follows. Lake Jackson (30.52872°N, 84.35580°W). Gravid female. 28 May 2004. Matthew J. Aresco (MJA). Florida Museum of Natural History (FLMNH) Herpetology Department photographic archive (UF 144701, color slide). MJA had earlier observed two adult females and three adult males here in 2000–2001. Additional records from Leon County include: UF 144704, color slide; UF 144703, color slide; and UF 144702, color slide. In addition, we have observed *T. s. elegans* at McCord Pond (30.47400°N, 84.26162°W), Tom Brown Park Pond

(30.4419°N, 84.2146°W), San Luis Pond (30.45951°N, 84.32244°W); Goose Pond (30.47897°N, 84.24391°W), and Hidden Pond (30.47165°N, 84.32929°W).

Besides recording nesting and gravid females, MJA recorded several instances of hybridization with native *T. s. scripta*, based on intermediate color patterns. These included three hybrids from Lake Jackson, 2 July 2000, UF 141456–141458, and nine hatchlings from Lake Jackson, 9 May 2000, 11 June 2000, 14 June 2000, and 28 June 2000 (unvouchered DOR specimens). All specimens and photographic identifications verified by Kenneth Krysko.

Trachemys. s. scripta is the dominant emydid in many lentic freshwater bodies in the Florida panhandle, including Leon County. *Trachemys. s. elegans* poses a real threat of hybridization and genetic swamping to this native subspecies. We have already recorded evidence of hybridization at Lake Jackson and suspect it at most of the listed sites. We therefore have called upon state regulatory agencies to institute an immediate prohibition on further sales and importation of *T. s. elegans* into the state.

Submitted by **MATTHEW J. ARESCO**, Florida State University, Tallahassee, Florida 32306, USA (e-mail: aresco@bio.fsu.edu); and **DALE R. JACKSON**, Florida Natural Areas Inventory, Florida State University, 1018 Thomasville Road, Suite 200-C, Tallahassee, Florida 32303, USA (e-mail: aresco@bio.fsu.edu).

LACERTILIA

AMPHISBAENA DUBIA. BRAZIL: MINAS GERAIS: Belo Horizonte, Serra do Curral (19°55'S, 43°54'W, 1100 m elev.), area of highlands ("campo rupestre") in transition region between the Atlantic Forest and "Cerrado" biomes. 15 July 2005. P. R. Evers Jr., A. L. Silveira and D. S. Lima Filho. Museu Nacional, Rio de Janeiro, Brazil (MNRJ 13254). Verified by R. Fernandes. Species previously known from the states of São Paulo, Paraná, Santa Catarina, and one record in Minas Gerais, Brazil (Barros Filho et al. 2005. Herpetol. Rev. 36[3]:335; Gans 1964. Breviora 205:1–11; Peters and Orejas-Miranda 1970. Catalogue of the Neotropical Squamata: Part II Lizards and Amphisbaenians. U.S. Natl. Mus. Bull. 297:31; Vanzolini 2002. Pap. Avul. Zool. 42[15]:351–362). Second state record and the northern limit of its known distribution, ca.130 km NE from the closest previous record (Brazil, Minas Gerais, Ritápolis municipality; Barros Filho et al. 2002, *op. cit.*).

Submitted by **PAULO R. EVERS JR.** (e-mail: pauloevers@hotmail.com), **ADRIANO LIMA SILVEIRA** (e-mail: biosilveira@yahoo.com.br), and **DORIVAL SANTOS LIMA FILHO** (e-mail: lima.dorival@gmail.com), Setor de Herpetologia, Departamento de Vertebrados, Museu Nacional, Universidade Federal do Rio de Janeiro, Quinta da Boa Vista, São Cristóvão, CEP 20940-040, Rio de Janeiro, RJ, Brazil.

BACHIA PYBURNI. BRAZIL: AMAZONAS: Municipality of São Gabriel da Cachoeira, Parque Nacional do Pico da Neblina: Morro dos Seis Lagos (0°17'28"N; 66°40'57"W), 12 May 2004. Coleção de Anfíbios e Répteis, Instituto Nacional de Pesquisas da Amazônia, Manaus, Amazonas, Brazil (INPA-H 12754, SVL 84.4 mm; body mass in life 4 g); terra firme forest near right bank of the Tucano River (0°37'20"N; 65°55'26"W), 12 November 2004 (INPA-H 12753, SVL 77.8 mm; body mass in life 5.4 g), and trail in terra firme forest (0°38'34"N; 66°00'46"W), 26 September 2005 (INPA-H 14967, SVL 90.7 mm; body mass in life 4 g). Vinicius T. Carvalho and L. Bonora. Verified by M. Hoogmoed. This species was previously known from Colombia and Venezuela (Kizirian and McDiarmid 1998. Herpetologica 54:245–253). These specimens represent the first Brazilian records, extending the known distribution 318 km, 394 km, and 384 km (airline) east, respectively, from the type locality in the Vaupés River drainage, SW Colombia (1°01'N; 69°27'W) and 83 km (airline) from the paratype in the western part of Cerro de la Neblina, southern Venezuela (0°49'50"N; 66°09'40"W) (Kizirian and McDiarmid 1998, *op. cit.*).

PETROSAURUS REPENS (Short-nosed Rock Lizard). MÉXICO: BAJA CALIFORNIA SUR: Coronados Island. (26°7'43.7"N, 111°16'37.1"W). 12 September 2004. Crystian S. Venegas-Barrera. Verified by Jesse L. Grismer. La Sierra University Digital Photo Catalogue (LSUDPC 688–89). First record for this species on Coronados Island; the only other island in the Sea of Cortés where the species is known to occur is Danzante (Grismer 2002. Amphibians and Reptiles of Baja California: Including Its Pacific Islands and the Islands in the Sea of Cortez. Univ. California Press, Berkeley).

Submitted by **CRYSTIAN S. VENEGAS-BARRERA**, **GUSTAVO ARNAUD**, Centro de Investigaciones del Noroeste, Baja California Sur, La Paz, B.C.S. 23090, México; **LEE L. GRISMER**, Departament Biology, La Sierra University, Riverside, California 92515, USA; and **ÁNGEL RODRÍGUEZ**, Centro de Investigaciones del Noroeste, Baja California Sur, La Paz, B.C.S. 23090, México (e-mail: sadiel@cibnor.mx).

PLESTIODON LYNXE BELLI (Bell's Oak Forest Skink). MÉXICO: JALISCO: Municipality of Quila (20°17'N, 104°03'W) 2000 m elev. P. Ponce-Campos, R. and H. Romero-Contreras, and R. Romero-Luna. 5 March 2003. Verified by H. M. Smith. Bosque Tropical Herpetological Collection (BT, M-010). First record for Jalisco and a range extension of ca. 315 km N of nearest confirmed record, 16 mi. W Milpillas, Zacatecas (Webb 1968. Publ. Mus. Michigan State Univ. Biol. Ser. 4:1–28). One possible Jalisco record of *Eumeces l. lynxe*, reported by Taylor (1935. Univ. Kansas Sci Bull XXIII:1–643), was determined by Webb (*op. cit.*) to be a *E. dugesi*.

Submitted by **PAULINO PONCE-CAMPOS** and **RODOLFO ROMERO-CONTRERAS**, Bosque Tropical, A.C. Apartado Postal 5-515, Guadalajara, Jalisco 45042, México; e-mail: poncecp@hotmail.com.

PLESTIODON SEPTENTRIONALIS OBTUSIROSTRIS (Southern Prairie Skink). USA: TEXAS: JACK CO.: immediately adjacent to FM road 3324 (33.112° N, 98.122° W; 380 m elev.). 1 April 2005. Jesse M. Meik and A. Michelle Lawing. Verified by Carl J. Franklin. University of Texas at Arlington transparency collection (UTA 33306–07). Two individuals were found at 1630 h, beneath separate small limestone slabs, part of a small, scattered rock field within a mosaic of open pasture, tallgrass prairie, and post oak woodland. The air temperature was 15.2°C and the surface temperature under the rocks ranged from 18.8–20.6°C. First county record (Dixon 2000. Amphibians and Reptiles of Texas. 2nd Edition. Texas A&M Univ. Press, College Station).

Submitted by **A. MICHELLE LAWING** and **JESSE M. MEIK**, Department of Biology, The University of Texas at Arlington, Arlington, Texas 76012, USA; e-mail: jmeik@uta.edu.

TROPIOCOLOTES STEUDNERI (Steudner's Dwarf Gecko). IRAN: Qeshm Island: in the southern part of Qeshm Isand, out of Qeshm city (26°58'N, 56°16'E), ca. 100 m from the sea. S. M. Dakhteh and K. Kamali. 4 April 2004 at 2200 h. ZMGU 840. Verified by Haji Gholi Kami and Steven C. Anderson. This is the first record of this species from Qeshm Island and the third known specimen from Iran. The specimen fits the diagnosis and color pattern in Anderson (1999. The Lizards of Iran. SSAR Contribution to Herpetoloy, Ithaca, New York) and with the descriptions of Anderson's (MMTT 1048) and Guibé's (MNHNP 1966.18) specimens, both from the vicinity of Bandar-e Lengeh (26°33'N, 54°53'E), on the coastal mainland across a narrow stretch of the Persian Gulf from Qeshm Island. See Anderson (1999:197–198) and Guibé (1966. Bull. Mus. Nat. Hist. nat., Paris, ser. 2, 38[2]:337–346) for further remarks on this taxon.

SERPENTES

CLELIA QUIMI. BRAZIL: BAHIA: Municipality of Paulo Afonso, Usina Hidrelétrica Itaparica (09°21'S, 38°14'W), area with typical caatinga vegetation. 30 September 1988. U. Simon. Fundação Ezequiel Dias, Belo Horizonte, Minas Gerais, Brazil (FUNED 34). MINAS GERAIS: Municipality of Três Marias, Km 289 of BR 040 (18°12'S, 45°15'W). 10 November 2002. A. L. Silveira. Museu Nacional, Universidade Federal do Rio de Janeiro, Rio de Janeiro, RJ, Brazil (MNRJ 10925). Verified by R. Fernandes. Species previously known from the Atlantic Forest in the states of Santa Catarina, Paraná, São Paulo, and Espírito Santo, and areas of Cerrado in states of São Paulo, Minas Gerais, and Distrito Federal, Brazil (Franco et al. 1997. J. Herpetol. 31[4]:483–490). First record from the state of Bahia, extends known distribution ca. 1295 km northeast from the closest previous record (Brazil, Distrito Federal, Brasília Municipality; Franco et al., *op. cit.*), also first record from Caatinga vegetation. The record in Três Marias fulfills a gap of distribution between the south Minas Gerais and Distrito Federal localities (Franco et al., *op. cit.*).

Submitted by **ADRIANO LIMA SILVEIRA**, Setor de Herpetologia, Departamento de Vertebrados, Museu Nacional, Universidade Federal do Rio de Janeiro, Quinta da Boa Vista, São Cristóvão, CEP 20940-040, Rio de Janeiro, RJ, Brazil, e-mail: biosilveira@yahoo.com.br; **GISELLE AGOSTINI COTTA**, Serviço de Animais Peçonhentos, Fundação Ezequiel Dias, Rua Conde Pereira Carneiro, nº 80, Bairro Gameleira, CEP 30510-010, Belo Horizonte, MG, Brazil; e-mail: crotalus@funed.mg.gov.br.

COELOGNATHUS FLAVOLINEATUS (Yellow Striped Ratsnake). THAILAND: PRACHIN BURI: NADI: BUPHRAM. Water Reservoir for the village of Buphram. (14°20'30"N, 101°49'35"E), ~485 m elev. 25 June 2004. (FMNH 263527). Daryl R. Karns and John C. Murphy. NAKHON RATCHASIMA: WANG NAM KHIEO: UDON SAP. Entrance to Sakaeret Biosphere Reserve (~14°30'32"N, 102°02'45"E), 185 m elev. 6 July 2004. CUBMZR 2005.9. Jacques Hill. Verified by Tanya Chan-ard. These localities are about 28 km apart along Highway 304. The adult male specimen from Buphram was salvaged from a fishermen's gill net. The Sakaeret specimen was DOR on highway 304 near the entrance to the Reserve and a second Sakaeret specimen was observed on the Reserve's driveway (JH). Evidence of the Buphram population is also supported by FMNH 180298 collected in 1969 by W. R. Heyer at Khao Yai National Park (the eastern edge of the Park is on the opposite side of the road from the Buphram Reservoir). The 1969 specimen has apparently been overlooked in recent literature (Schultz. 1996. A Monograph of the Colubrid Snakes of Genus *Elaphe* Fitzinger. Koeltz Scientific Books, Havlickuv Brod; Grumprecht 1996. Sauria Suppl. 18:373–376; Grossman and Tillack, 1998. Sauria 20:43–45). Schultz (1996) and Grumprecht (1996) report a single specimen from Pak Chong, Nakhon Ratchasima Province and wrote that it "urgently requires confirmation." Because the Pak Chong specimen was located near an animal dealer's compound, it was suggested that the individual may represent a feral population. This population is also of interest because, prior to its collection at Pak Chong, this species was known only from continental Asia south of 7°N latitude and all Thai specimens were from the Peninsula (Schultz, 1996). However, Grossman and Tillack (1998) also reported specimens from Vietnam suggesting the species may be more widespread than previously thought. The Buphram specimen extends the range about 60 km east. The Sakaeret specimen extends the range about 50 km east of the Pak Chong locality. The Sakaeret Biosphere Reserve had an extensive herpetofaunal survey done in the late 1960s (Inger and Colwell 1977. Ecol. Monogr. 47:229–253). They did not mention this species because the 1969 specimen (FMNH 180298) was collected off the Reserve. It is unlikely that a large (1.5–2 m) diurnal snake would be overlooked during an 11-month herpetofaunal survey that obtained 4400 specimens. Two of us (DRK and JCM) visited Sakaeret in 2003 at which time we found a neonate *Python molurus* on the driveway of the Reserve, this species was also not reported by Inger and Colwell (1977, *op. cit.*) and suggests to us that recent environmental changes might have allowed *C. flavolineatus* and *P. molurus* to expand their distributions into the Sakaeret Reserve.

PITUOPHIS CATENIFER SAYI (Bullsnake). USA:

MINNESOTA: MARSHALL CO.: near Holt: County Rd 141 approx 2 km of Co. Hwy 7 (48° 16'30" 96° 16'00"). 26 September 2005. Joe Hermreck. DOR subadult male on gravel road in good habitat. Bell Museum of Natural History Collection JFBM 14448. Verified by Tony Gamble. Extends range 85 km north of the previous record for the state (Oldfield and Moriarty 1994. Amphibians and Reptiles Native to Minnesota. Univ. of Minnesota Press, Minneapolis).

Submitted by **JOHN J. MORIARTY**, Bell Museum of Natural History, Univ. of Minnesota, Minneapolis, MN 55455; e-mail: frogs@umn.edu.

PSEUDOTOMODON TRIGONATUS (Culebra Enhebrada). ARGENTINA: CATAMARCA: Departamento Tinogasta: 4 km from Río La Punta to Tinogasta city (28°04'S; 67°34W) on National Road 60. 7 December 1985. E. Pereyra, O. Pagaburo and J. Bracamonte. Herpetological collection, Instituto de Herpetología, Fundación Miguel Lillo, Tucumán, Argentina (FML 1635). Medanitos (27°32'S; 67°36'W, 1650 m.a.s.l.), 7 March 1987, O. Pagaburo and J. Bracamonte (FML 1685-1 and 1685-2). TUCUMÁN: Departamento Tafí del Valle: 4 km NW from Amaicha del Valle (26°36' S; 65°55' W) on Ruta Provincial 307. 12 January 2006. G. A. Gallardo (FML 16739). All verified by G. Scrocchi. Endemic Argentinian species, previously known in the west of the country from Neuquén and Río Negro to La Rioja, east to Santiago del Estero and Córdoba, and a supposed disjunct area in southern Buenos Aires and La Pampa (Cei 1983. Reptiles del noroeste, nordeste y este de la Argentina. Museo Regionale di Scienze Naturali, Torino. Monografía XIV: 949 pp.; Giraudo and Scrocchi 2002. Smithsonian Herpetological Information Service 132:1–53). The records from Catamarca confirms the presence of the species in the province, which previous authors (Williams and Francini 1991. Boll. Mus. reg. Sc. nat. Torino 9[1]:55–90; Giraudo and Scrocchi, *op. cit.*) have mentioned that "need confirmation." The record from Tucumán is the first from the province and the northermost for the species, and extends distribution approximatelly 230 km airline from the La Rioja – Catamarca boundary, the closest area mentioned by Cei (*op. cit.*) without voucher reference.

Submitted by **GABRIELA A. GALLARDO** Instituto de Herpetología, Fundación Miguel Lillo, Miguel Lillo 251, 4000 Tucumán, Argentina; e-mail: gabrielagall@gmail.com.

STORERIA OCCIPITOMACULATA (Red-bellied Snake). USA: WISCONSIN: VERNON CO.: U.S. Highway 14/61 just east of County Trunk T (T11N, R3W, S7). 2 August 2002. Joseph A. Cochran. James Ford Bell Museum of Natural History, University of Minnesota (JFBM 14450). Verified by Tony Gamble. Dead on road; first vouchered record from county (Casper, G.S. 1996. Geographic distribution of the amphibians and reptiles of Wisconsin. Milwaukee Public Museum [MPM], Milwaukee, WI). Substantiates sight records ca. 25 km west northwest at ca. 0.4 km east of jct of Tewalt Rd and Anderson Rd (T\h \r 112N, R6W, S22 SW1/4 of NE1/4; Wisconsin Herp Atlas MADA 18, David G. \h \r 1Matheys), and three observations ca. 32–39 km northeast at \h \r 1Wildcat Mountain State Park (T\h \r 114N, R1W, S29, Wisconsin Herp Atlas THSA 51, Sam Thayer; T\h \r 114N, R1W, S11 SE1/4, Wisconsin Herp Atlas THSA 58, Sam Thayer; T\h \r 114N, R2W, S12, Wisconsin Herp Atlas THSA 58, Sam Thayer). Nearest records documented by specimens are southeast ca. 25 km (Richland County, MPM 6939, 6940) and north ca. 66 km (Monroe County, MPM 23404).

SSAR Treasurer Vacancy

The Society for the Study of Amphibians and Reptiles seeks applicants for the office of Treasurer. This is a non-paid position with funds available for work-study assistance. Term length is open-ended. Duties are as follows: maintain fiscal records of the Society; make monetary disbursements; coordinate payment to printers for costs of publications after approval by respective editors; invoice reprint orders; interact with Publications Secretary/Membership Office relative to stocks of publications and counts of current number of members; submit annual report which includes budget request for following year to the Secretary prior to annual meeting of the Board. Membership management, investment management, and IRS reports are not part of current duties. The office provides an important contribution toward continuity of information within the Society, thus, attendance at the annual meetings is mandatory. Individuals interested in the position should contact Kirsten E. Nicholson at knicholson@biology2.wustl.edu no later than 16 July 2006.

Herpetological Review, 2006, 37(2), 244–246.

New Distributional Records for Reptiles from North Carolina

JEFFREY C. BEANE
and
WILLIAM M. PALMER
North Carolina State Museum of Natural Sciences, Research Laboratory
4301 Reedy Creek Road, Raleigh, North Carolina 27607, USA
e-mail (JCB): jeff.beane@ncmail.net

The geographic distribution of reptiles in North Carolina (USA) was summarized by Palmer and Braswell (1995) and supplemented by Beane (1998). We here report new distributional records based upon specimens verified by Alvin L. Braswell and housed at the North Carolina State Museum of Natural Sciences (NCSM).

Crocodylia

Alligator mississipiensis (American Alligator). COLUMBUS CO.: 6.9 km S Lake Waccamaw (town), Lake Waccamaw dam spillway. 24 June 1999. D. G. Cooper et al. NCSM 60135. First voucher for county. Palmer and Braswell (1995) reported observational records.

Testudines

Chelydra serpentina serpentina (Eastern Snapping Turtle). BURKE CO.: South Mountains State Park, 10.8 km WSW Pleasant Grove. 28 June 1999. A. L. Braswell, R. Bowers, and D. Wise. NCSM 60098. New county record. LINCOLN CO.: ca. 4.5 km ENE Lowesville, just SW Cowan's Ford dam. 5 April 1968. E. E. Brown. NCSM 56094. First voucher for county. Palmer and Braswell (1995) reported an observational record. MOORE CO.: 4.0 km SE Southern Pines. 9 June 1973. J. H. Carter III. NCSM 62324. 8.4 km W.SW Pinebluff. 6 September 1998. J. C. Beane and J. T. Finnegan. NCSM 58157. First vouchers for county. Palmer and Braswell (1995) reported an observational record. NEW HANOVER CO.: 2.1 km WNW Carolina Beach, Carolina Beach State Park (34°02'32"N, 77°54'49"W). 14 May 2002. G. S. Grant. NCSM 63500. New county record. STOKES CO.: 0.8 km SSE Danbury. 4 June 1951. E. E. Brown. NCSM 56089. New county record.

Chrysemys picta picta (Eastern Painted Turtle). CUMBERLAND CO.: *ca*. 5.6 km WSW Spring Lake, Fort Bragg (UTM Zone 17: N3890589 m, E678587 m). 3 June 2002. B. S. Ball. NCSM 64211. First voucher for county. Brimley (1944) and Palmer and Braswell (1995) reported an observational record. WARREN CO.: Warrenton. 10 June 1997. S. Fearne. NCSM 55630. New county record.

Deirochelys reticularia reticularia (Eastern Chicken Turtle). CUMBERLAND CO.: ca. 7.2 km ESE Lena, White Pond Bay. 2 June 2000. G. S. Grant. NCSM 60846. First voucher for county. Brimley (1944) and Palmer and Braswell (1995) reported an observational record.

Pseudemys concinna concinna (Eastern River Cooter). DURHAM CO.: *ca*. 8.0 km SE Bahama, Eno River, Butner Game Lands, Butner Depot Waterfowl Impoundment. 18 January 2003. J. S. Zawadowski and R. B. G. Bogwalker. NCSM 64390. New county record. UNION CO.: 4.2 km N New Salem along Rocky River. 7 May 2000. A. L. Braswell, S. L. Braswell, et al. NCSM 60369. New county record.

Sternotherus odoratus (Stinkpot). ANSON CO.: ca. 4.0 km SSE Peachland at Brown Creek. 16 May 1975. E. E. Brown. NCSM 53222. First voucher for county. Brown (1992) and Palmer and Braswell (1995) reported a visual record, apparently from this same locality. HYDE CO.: 10.5 km E Fairfield. 31 August 1998. R. P. Fengya. NCSM 58849. New county record.

Terrapene carolina carolina (Eastern Box Turtle). CALDWELL CO.: 4.0 km NNW Lenoir. 4 August 1962. T. D. Murphy and D. M. Davis. NCSM 54491. 8 km NE Lenoir. 3 August 1962. T. D. Murphy and D. M. Davis. NCSM 54504. 13 km ENE Lenoir. 24 July 1962. J. R. Bailey et al. NCSM 54528. First vouchers for county. Van Devender and Nicoletto (1983) and Palmer and Braswell (1995) reported observational records. IREDELL CO.: 4.3 km W Mooresville. 5 August 1962. T. D. Murphy and D. M. Davis. NCSM 54502. New county record. JACKSON CO.: 4.8 km S Cullowhee. 21 May 1974. J. R. Bailey. NCSM 54533. New county record. MARTIN CO.: 2.0 km SSE Williamston. 25 November 2001. A. B. Braswell and S. L. Braswell. NCSM 62534. First voucher for county. Palmer and Braswell (1995) reported a visual record. YADKIN CO.: ca. 3.2 km W Yadkinville. 3 August 1962. T. D. Murphy and D. M. Davis. NCSM 54527. First voucher for county. Palmer and Braswell (1995) reported observational records. YANCEY CO.: ca. 3.2 km NNE Burnsville. 13 July 1966. A. Sharer et al. NCSM 54512. New county record.

Trachemys scripta scripta (Yellow-bellied Slider). ROWAN CO.: 6.8 km NE Salisbury along Grants Creek. Ca. December 1997. M. J. Baranski. NCSM 58014. New county record.

Lacertilia

Cnemidophorus sexlineatus sexlineatus (Eastern Six-lined Racerunner). FRANKLIN CO.: 6.8 km NNE Franklinton. 20 Sept. 1997. R. Mullins. NCSM 53721. New county record.

Eumeces anthracinus (Coal Skink). POLK CO.: 3.1 km WNW Tryon, Melrose Mountain. 30 September 2001. D. A. Jackan et al. NCSM 62419. New county record. Extends range ca. 33 km SE of nearest record in Henderson County.

Eumeces inexpectatus (Southeastern Five-lined Skink). WARREN CO.: ca. 12.5 km NE Vaughn. 8 October 1972. J. R. Bailey and M. Bailey. NCSM 41436. New county record.

Ophisaurus attenuatus longicaudus (Eastern Slender Glass Lizard). BEAUFORT CO.: 5.0 km ESE Bunyan. 15 May 1992. R. W. Gaul, Jr. NCSM 31806. New county record. GRANVILLE CO.: ca. 6.4 km W Stovall. 24 May 1995. G. Parham. NCSM 57551. New county record.

Ophisaurus ventralis (Eastern Glass Lizard). HARNETT CO.: 9.3 km ESE Spout Springs (35°14'4.25"N, 78°57'51.12"W). 24 August 2001. C. L. Bryan. NCSM 62575. New county record. MONTGOMERY CO.: 8.1 km SSE Emery. 16 June 2000. J. C. Beane and S. L. Alford. NCSM 60405. New county record. Extends range ca. 16 km NW of nearest records in Moore and Richmond counties.

Scincella lateralis (Ground Skink). MACON CO.: ca. 3.2 km NNW Franklin. 29 October 1997. D. Crisp. NCSM 54610. New county record. Fills gap between Clay and Jackson counties. RANDOLPH CO.: ca. 8 km NNE Farmer, Ridges Mountain. 15 March 1998. J.

C. Beane et al. NCSM 57408. First voucher for county. Palmer and Braswell (1995) reported observational records.

Serpentes

Agkistrodon contortrix (Copperhead). Davie Co.: ca. 5.8 km SSE Advance. 27 May 1994. H. Woltz. NCSM 36276. First voucher for county. Palmer and Braswell (1995) reported a sight record. Forsyth Co.: ca. 6.4 km NW center Winston-Salem. 10 August 1998. E. Brandon. NCSM 58148. First voucher for county. Palmer and Braswell (1995) reported an observational record.

Coluber constrictor constrictor (Northern Black Racer). Wilkes Co.: 6.6 km WNW Traphill. 31 May 1999. J. C. Beane and V. K. Rice. NCSM 60083. First voucher for county. Palmer and Braswell (1995) reported an observational record.

Crotalus horridus (Timber Rattlesnake). Alleghany Co.: 4.0 km SW Whitehead. 29 August 1998. P. D. McMillan. NCSM 58188. First voucher for county. Palmer and Braswell (1995) reported observational records.

Farancia abacura abacura (Eastern Mudsnake). Gates Co.: 5.6 km ENE Gatesville. 5 October 2000. J. C. Wyche. NCSM 61568. First voucher for county. Palmer and Braswell (1995) reported observational records.

Farancia erytrogramma erytrogramma (Rainbow Snake). Washington Co.: 12.7 km SSW Cherry, S shore of Lake Phelps. 22 May 1997. S. A. Shearin. NCSM 53554. New county record.

Heterodon platirhinos (Eastern Hog-nosed Snake). Gates Co.: ca. 6.4 km NE Gatesville, Merchants Millpond State Park. 12 April 1998. J. C. Wyche. NCSM 57875. 5.6 km ENE Gatesville. 1997. F. K. Williams. NCSM 57876. 5.6 km ENE Gatesville. 14 October 1998. J. C. Wyche. NCSM 61745. First vouchers for county. Palmer and Braswell (1995) reported an observational record. Surry Co.: 0.6 km SW Low Gap. 5 September 1998. L. Marion. NCSM 58151. 8 km S Low Gap. 10 October 1998. S. K. Eanes. NCSM 60160. New county records.

Lampropeltis calligaster rhombomaculata (Mole Kingsnake). Granville Co.: 3.5 km NNW Butner. 26 April 1998. M. E. Welker. NCSM 57878. 5.3 km NNW Stem. 6 June 2001. M. E. Welker. NCSM 61885. First vouchers for county. Palmer and Braswell (1995) reported an observational record. Wilkes Co.: 6.8 km W Traphill. 9 May 1998. D. T. Sawyer. NCSM 58000. New county record. Extends range ca. 36 km W and ca. 39 km NNW of nearest records in Surry and Iredell counties, respectively. Partially fills range hiatus shown in Conant and Collins (1998).

Lampropeltis getula getula (Eastern Kingsnake). Davie Co.: 3.2 km NE Cooleemee. 13 May 2000. D. T. Sawyer and T. B. Sawyer. NCSM 60386. New county record. Wilkes Co.: 0.6 km SW Traphill. 22 June 1998. D. T. Sawyer. NCSM 58150. 1.6 km ENE Traphill. 16 October 2000. D. T. Sawyer. NCSM 61558. 6.9 km W Traphill. 6 May 2002. T. B. Sawyer. NCSM 63012. First vouchers for county. Beane (1998) reported a photographic record.

Opheodrys aestivus (Rough Greensnake). Alleghany Co.: 3.6 km ESE Citron, Doughton Park Recreational Area. 10 August 1996. D. L. Stephan. NCSM 58513. New county record. Extends range ca. 18 km NW of nearest record in Wilkes County. Partially fills range hiatus shown in Conant and Collins (1998). Specimen was collected at an elevation of ca. 1095 m, exceeding the previous elevation record for North Carolina of ca. 914 m (Huheey and Stupka 1967; King 1939; Palmer and Braswell 1995). Lee Co.: 4.8 km NW Sanford. 15 October 1996. A. L. Kyles. NCSM 45080. New county record. Rutherford Co.: 2.3 km NW Hollis. 26 May 2002. G. R. Mayfield III. NCSM 63772. First voucher for county. Weller (1930) and Palmer and Braswell (1995) reported observational records. Vance Co.: 6.0 km ENE Williamsboro, Kerr Lake State Recreational Area. 31 August 2000. M. M. Mohamed. NCSM 61559. New county record.

Regina septemvittata (Queen Snake). Harnett Co.: 6.4 km SSE Spout Springs, Ft. Bragg, "Overhills Tract" (UTM Zone 17: N3898806 m, E679904 m). 16 July 2002. A. Westmoreland and B. S. Ball. NCSM 64212. New county record.

Storeria dekayi (Dekay's Brown Snake). Franklin Co.: 11.3 km SW Louisburg. 15 June 1999. D. Cash. NCSM 60091. New county record. Hoke Co.: 1.1 km ENE Antioch. 7 January 1998. J. C. Beane and R. A. Davis. NCSM 55511. New county record.

Storeria occipitomaculata occipitomaculata (Northern Red-bellied Snake). Cabarrus Co.: ca. 8 km E Davidson, Egg Rock Woods. 1 May 1949. T. Daggy. NCSM 52428. New county record.

Tantilla coronata (Southeastern Crowned Snake). Craven Co.: 3.9 km SSW Askin, Cool Springs Environmental Center. 2 July 2002. J. G. Hall. NCSM 64952. 4.0 km SSW Askin, Cool Springs Environmental Center. 16 July 2002. J. G. Hall. NCSM 64953. New county records. Harnett Co.: 7.1 km SE Spout Springs, Fort Bragg, Overhills Tract. 25 April 2002. B. S. Ball and A. Young. NCSM 63009. First voucher for county. Palmer and Braswell (1995) reported an observational record.

Virginia valeriae valeriae (Eastern Smooth Earth Snake). Moore Co.: 2.9 km SE Jackson Springs. 11 September 2002. S. L. Alford. NCSM 64001. New county record. Richmond Co.: 5.7 km E Ellerbe. 8 September 1999. S. L. Alford. NCSM 60153. New county record.

Acknowledgments.—We thank all those whose field work resulted in new distributional records. A. L. Braswell and S. D. Busack reviewed the manuscript.

New Geographic Distribution Records of Amphibians and Reptiles in Texas

CHRIS T. McALLISTER
Department of Biology, Angelo State University
San Angelo, Texas 76909, USA
e-mail: drctmcallister@aol.com

Since the publication of Dixon's second edition of *Amphibians and Reptiles of Texas* (2000) and Werler and Dixon's *Texas Snakes* (2000), numerous new county records have been documented for various amphibians and reptiles of the state (Bryson and Mueller 2002; LaDuc and Infante 2001; and others). A recent examination of the Angelo State Natural History Collection (ASNHC) has yielded additional records not documented over the last half-decade. Herein, I report 11 new county records for three amphibian and seven reptilian taxa from Texas. Specimens were verified by J. Kelly McCoy.

Anura

Bufo debilis debilis (Eastern Green Toad). Irion Co.: 1.6 km E Arden Rd. off FM 853. 19 April 1990. D. A. Trudo. ASNHC 12748. New county record that fills a distributional gap between Reagan and Tom Green counties.

Rana berlandieri (Rio Grande Leopard Frog). Crosby Co.: 1.6 km E Cone on FM 193 at Crawfish Creek. 11 April 1969. A. Flury. ASNHC 13675. Nolan Co.: 19.3 km NW Blackwell, Melvin Tubb Ranch. 26 July 1976. A. Flury. ASNHC 13625–13627, 13629–13632, 13652–13653. New county records. The Crosby Co. site is well outside the range depicted in Dixon (2000, see map. 35) and represents the northernmost locale for the species in the state.

Rana blairi (Plains Leopard Frog). Denton Co.: 9.7 km NE Lewisville at State Fish Hatchery. 2 June 1970. A. Flury. ASNHC 13693. New county record that fills small distributional gap between Dallas and Wise counties.

Testudines

Apalone spinifera guadalupensis (Guadalupe Spiny Softshell). Irion Co.: 1.6 km E Arden off FM 853 at Big Rocky Creek. 22 April 1990. D. A. Trudo. ASNHC 12762. New county record that extends range W from Tom Green County. A larger distributional gap remains for *A. spinifera* to the west in the state.

Apalone spinifera pallida (Pallid Spiny Softshell). Callahan Co.: 1.6 km E Eula at Pecan Bayou. 14 April 1990. J. Berry. ASNHC 12701. New county record that fills a distributional hiatus between Eastland and Taylor counties.

Lacertilia

Hemidactylus turcicus turcicus (Mediterranean Gecko). Live Oak Co.: 16.1 km N Mathis at Lake Corpus Christi. 7 April 1990. K. E. Sargent. ASNHC 12860–12864. New county record. This small introduced gecko continues to be reported from new locales in Texas with no less than eight new county records reported in *Herpetological Review* over the last five years.

Serpentes

Elaphe emoryi emoryi (Northern Plains Rat Snake). Mitchell Co.: 11.3 km S Ira on US 380, 12.9 km S on St. Hwy 350. 21 March 1990. A. M. Bragg. ASNHC 12727. New county record that fills a distributional gap between Howard and Nolan counties.

Hypsiglena torquata janii (Texas Night Snake). Runnels Co.: 20.9 km NW Ballinger at Underwood Farm. 27 April 1990. D. C. Stone. ASNHC 12657–12658. New county record filling a distributional hiatus between Coleman and Coke counties.

Tantilla nigriceps (Plains Black-headed Snake). Callahan Co.: 1.6 km W FM 604, 8.0 km S Clyde at Berry Farm. 28 April 1990. J. Berry. ASNHC 12715. New county record. Fills distributional gap between Coleman and Shackelford counties; larger distributional gap exists to the east in a 12-county area of central Texas.

Virginia striatula (Rough Earthsnake). Irion Co.: Butch Davis Place (specific locality not known). 13 May 1975. D. Davis. ASNHC 13101. New county record. This locale is outside the range depicted in Dixon (2000, map. 151) and Werler and Dixon (2000, plate 168) and extends the range two counties westward from Concho County. This record appears to be authentic, not related to specimens reported previously from El Paso, King, and Lubbock counties believed to be accidental introductions related to horticulture trade (see Dixon, 2000). However, Werler and Dixon (2000) do not mention these accidental records but show an additional record for *V. striatula* in Garza County while omitting the record from El Paso County.

Acknowledgments.—I thank J. Kelly McCoy, Curator of Amphibians and Reptiles (ASNHC), for specimen verification and allowing me access to the collection, and Stanley E. Trauth for reviewing this manuscript.

e-mail: atelopus@andigena.org

In recent decades, taxonomic knowledge of Neotropical amphibians has increased rapidly and significantly. In the face of destruction of natural habitats, there is a great need to understand the biota that surrounds us. The availability of new technologies and the increasing number of students of herpetology in the tropics have made advances in this field possible. Signigicantly, the most diverse countries in the world in amphibian diversity (all in the Neotropics) have taken a direct part in reviewing the most problematic groups of amphibians.

Glass frogs of the family Centrolenidae are among those groups of anurans that few people have dared to tackle. Others are *Leptodactylus, Eleutherodactylus*, and *Elachistocleis,* just to mention a few. Prior to the ground-breaking work of Lynch and Ruíz-Carranza in Colombia (Ruíz-Carranza and Lynch 1991 and subsequent papers), the family Centrolenidae was known poorly, chiefly through species descriptions (e.g., Goin 1963; Rivero 1968, 1986 for Venezuela alone), and a more comprehensive understanding of the group was lacking. Nonetheless, much additional study is needed, and this new book on glass frogs has appeared at an opportune time. It presents the results of more than 15 years of observations by José Ayarzagüena and Celsa Señaris in Venezuela (Ayarzagüena 1992; Señaris and Ayarzagüena 1993, 2001; Ayarzagüena and Señaris 1996; Señaris 1999; Duellman and Señaris 2003) and is mainly derived from the Ph.D. thesis of the latter author.

The book starts with acknowledgements and abstracts in Spanish and English. A general introduction to the Amphibia of Venezuela follows. The introduction is completed by an historical resumé of studies of the Centrolenidae throughout their range, a review of supraspecific classifications, and a subchapter about the family Centrolenidae in its Venezuelan context.

The materials and methods, covering both field and lab work, is comprehensive—detailing all measurements taken (morphology and morphometry), osteological methods, the study of tadpoles, and call analysis. The subsequent section is about the study area, which includes most of the Venezuelan bioregions important to glass frogs. It covers the geology and geomorphology of the country, hydrography, and physiographic and phytogeographic regions of Venezuela. Localities representative of different bioregions are described in detail and zoogeographic patterns of the Venezuelan herpetofauna are presented. A separate chapter outlines the 16 taxonomic characters employed in the study.

The longest part of the book provides a detailed account of each of the 23 species known for the country: five *Centrolene*, seven *Cochranella*, and 11 *Hyalinobatrachium*. The only species for which the account is rather sketchy is *Centrolene lema* Duellman and Señaris, 2003, which was not yet described formally when the text was initially sent to the publisher. Each account provides a complete synonymy, diagnosis, description (usually accompanied by drawings of the dorsal and lateral views of the head, and ventral views of hands, feet, and nuptial excrescences), coloration in life and in alcohol, osteology (usually with details of the skull, vertebral column, hand, humerus and spines), natural history, call description (with sonograms and oscilograms of almost all species), and description of the tadpole (also with a good schematic drawing); distribution, and comments or remarks. Accompanying point locality maps illustrate known Venezuelan localities. Following the accounts, the authors provide a dichotomous key to all species of Venezuelan glass frogs. This is quite simple to follow, except that its use requires males of *Centrolene* or *Cochranella.*

A long discussion follows, in which the authors comment on their findings and erect two new groups, one for Guayanan *Centrolene* (the *C. gorzulai* group) and another for Guayanan + Paria *Cochranella* (the *C. oyampiensis* group). In a biogeographic section, geographic, altitudinal, latitudinal, and spatial distribution are analyzed, centrolenid diversity per country is summarized, and instances of sympatry reviewed. "Conclusions and recommendations" summarizes the most significant findings and highlights the need for further research on glass frogs. A bibliography with 194 references ends the text section of the book.

Section IX (wrongly indicateded as VII) is a set of color plates, but only ten of the species are illustrated. It would have been useful to see all of the animals treated in the book in color, however, it is still an important contribution to provide the first color photos of selected species with restricted distributions, such as *Cochranella castroviejoi, C. helenae, C. revocata, C. vozmedianoi, Hyalinobatrachium antisthenesi, H. duranti, H. mondolfii*, and *H. taylori* (non-conspecific with *H. taylori* as treated by Lescure and Marty 2000, fide C. Señaris and S. Castroviejo, pers. comm.).

Finally, there are four annexes: a current checklist of all centrolenids, with summary distributional statements and comments about phenetic grouping; material examined; and a principal components analysis of the Venezuelan centrolenids.

There are a few typographic errors and some editorial inconsistencies. For example, the pagination indicated in the table of contents does not match the actual text and on page 249 the legend for Figure 170 repeats that for Figure 169, when it should say something like: "Distribución altitudinal de las diferentes especies venezolanas"... (Altitudinal distribution of different Venezuelan species...). However, some other issues are relevant to the use of

the volume. First, it appears to be difficult to acquire the book; indeed, I have not been able to locate it for sale in Venezuela. There is no indication of price and the main source of the book in Venezuela is directly from the first author. The problem must be the same in many other countries in which the book is likely to be of particular value. Finally, the book is written in Spanish, which is obviously good for all Spanish speakers, but perhaps makes it less accessible outside of Latin America. On the other hand, all herpetologists interested in Neotropical amphibians and reptiles really must have at least a reading knowledge of Spanish, and this book offers such people great opportunity to practice! Any minor criticisms aside, I must congratulate the authors for such an impressive effort, which undoubtedly contributes significantly to our understanding of this family of anurans.

and

KELLIE A. WATKINS-COLWELL
PriMed, 325 Reef Road, Suite 206
Fairfield, Connecticut 06430, USA

In the preface and introduction of this book, the author explains how she, an admitted non-herpetologist, became fascinated with snakes. Her initial ophidiphobia, caused by ignorance and the same taught fear that many people experience in early childhood, came to a head when her own son's close friend was bitten by a copperhead. Rather than reacting with the mindless fear one might expect, the author took it upon her self to learn more about snakes and overcome her own prejudices, and then to share this new found respect and appreciation with others through public lectures and a book on the subject. The author explains that when she first tried to learn about snakes she found that most of the literature available to her was written by professional herpetologists for other professionals and, thus, not in a language accessible to her. She then set out to produce a book geared specifically to other parents. A few reservations aside, she appears to have succeeded.

Following the Preface, Acknowledgements and Introduction, this book is organized into two main sections: General Information and Specific New England Snakes. The first section includes six chapters on General Biology, Behavior, Venomous Snakes and Snakebite, Mythology and Folklore, and Classification. The second includes sixteen chapters: one each on Colubridae and Viperidae, followed by individual accounts for all native New England snake species. There are five appendices: Diagrams of Important Scale Identification and Terminology of Timber Rattlesnake, Radiotelemetry Studies on Snakes, Captive Care, Range Maps and List of New England Snakes, and Northeast's Only Reptile and Amphibian Rehabilitation Center. A glossary of terms and an extensive bibliography complete the book.

Of the chapters in the first section, probably the most interesting is that on folklore. This section deals with a mixture of folk tales regarding snakes and commonly held snake myths. The coverage, though not by any stretch complete, does deal with the most

frequently encountered myths and provides information on their biological explanations.

The chapter on snake bite warns against some traditional first aide treatments, including the more ridiculous methods such as electroshock, many of which do more harm than good to the victim, and instead advises those bitten to seek medical attention immediately. The only other first aide discussed as viable is the use of an extractor mechanism, but not instead of medical attention. Such suggestions in a non-technical book are a welcome improvement on the diagrams showing the incision and suction technique that were a mainstay of some of the similarly-focused books that many of us grew-up with.

As noted above, the target audience for this book consists of concerned parents and new-comers to the world of snakes who simply want to learn as much as possible in easy-to-swallow morsels. However, it is difficult to say all that is important about such an interesting group of animals in relatively few words that are accessible to the lay person. Only a few pages and few, if any, literature citations are needed to tell a simple snake story, but authors who research the subject matter and learn more, and want to tell the reader more, quickly discover that it cannot be done in a *Readers Digest* format without leaving out significant and valuable information on these fascinating creatures.

There is a lot to say about snakes and the natural history information about each species could (and frequently does) fill volumes. Abbreviating any of this into a bite-sized morsel for the novice is difficult and the author likely discovered when writing the species accounts exactly why it is that other books on this subject originally appeared to her to be long and wordy. Her accounts are also fairly lengthy, but they written in a language and tone that should be palatable to the novice reader. The biological information in the text appears to be accurate and well-researched and some personal observations or human-interest stories are included for each species of snake.

The author of *Snakes of New England* also served as photographer. Her scientific photographs have been published in other works, including books on cell biology and at least one other on snakes. For this book she managed to photograph in the wild adults and juveniles of nearly every species (apparently augmenting with captives in some cases) as well as most of the major color variants within each species known to occur within New England.

Of the more than 350 color photographs of snakes or snake habitat, several are used more than once. For example, Figure 3.11 = 20.2 = 21.1; Figure 10.1 = 10.14 = 8.17 and is also repeated in an un-numbered series of photos on page 64, as are Figures 8.10, 8.14 (same as 9.12), 9.1, 9.9 (which is also 9.13), and 11.1. This causes some confusion and can result in individual photographs, rather than individual species of snake, becoming familiar to the reader. Additionally, while the composition of the photos is generally good, excellent in some cases, the exposure and focus are too frequently less consistent in quality: Figure 13.2 is nearly too dark to see more than the pink belly of the worm snake; Figure 15.5 is a photograph of a black racer on oak leaves and seems to be just out of focus; Figure 16.3 seems fuzzy, though not really out of focus, it could be a digital zoom of a scanned image; Figure 16.13 is a juvenile black rat snake sitting coiled on a rock, out of focus; and Figure 17.13 appears to be upside-down. For all this, however, the photographs capture aspects of the natural history of New England snakes that are rarely seen, let alone captured by a shutter. Among the more amazing shots, regardless of exposure, are photographs of hatching or birth in *Carphophis amoenus*, *Diadophis punctatus*, *Nerodia sipedon*, and *Agkistrodon contortix*. Also of interest are photographs of feeding by *Opheodrys vernalis* and *Storeria occipitomaculata*.

The illustrations are not as impressive as the photographs. Most are hand-drawn outline figures. Many appear to have been done as a high school art project, which may have been the case given the grass-roots aspect of this book. For example, the illustration of a cobra skeleton is crude at best, although it is clear what is intended. Illustrations in the dichotomous key are more useful and probably would be good references for the novice uncertain if a particular snake's scales are keeled or if the anal plate is divided or not. Line drawings of viperid fangs and mouth morphology are also acceptable and of likely use to the target audience. The maps are hand-colored with colored pencil.

This book was clearly a labor of love for the author and her helpers. However it could have benefited from additional external review and editing, including photo editing. Though well-researched and certainly a cathartic project for the author, the small details such as typographical errors, and inconsistent photo reproduction quality may be distracting to some readers. Still, the author has succeeded in producing a book on the snakes of New England (with information on snakes in general) for the non-professional reader. Though Conant and Collins (1998) may also be of use to this target audience, as it is to the rest of us, it covers all of the eastern U.S. and provides only abbreviated information about the biology of the species it covers. Klemmens (1993) is closer to the target focus, being about all amphibians and reptiles of Connecticut and adjacent areas (New York, Massachusetts and Rhode Island), but it contains details that may be too cumbersome for the novice reader and is out of print and not readily available. Behler and King (1979) covers all of North America, but also has inconsistent photo quality and is a generation out of date, though it is readily available in most shopping mall book stores.

Certainly this book could be of value to laypeople wanting information about New England snakes. However, the author appears to have missed an ideal opportunity to make her audience aware of the many local organizations and programs that promote the education and welfare of snakes and other reptiles. An appendix in *Snakes of New England* deals with a specific reptile rescue and rehabilitation center in Connecticut. The author claims that this is the only such organization in New England. Whether this is accurate or not may be subject to debate, but most of the many general wildlife rehabilitators in New England also deal with reptiles from time to time and several veterinarians treat native reptiles and amphibians each year. Nature centers at state parks and those run by private organizations including Connecticut Audubon Society also will care for wounded native reptiles and amphibians. Focusing on a single rehabilitation center may leave the reader unaware that there are, in fact, hundreds of people throughout the region in zoos, museums, herpetological and herpetocultural clubs, and governmental and non-governmental conservation agencies whose work benefits New England reptiles.

Bob Tipton's book and CD are clearly a labor of love. The author set out on an almost quixotic quest to link the common names used most comfortably by "most people" (Jonathan Campbell in the Foreword), especially native peoples and herpetoculturists, to the names used by scientists. To a large degree he has succeeded.

The heart of the CD is an Excel file containing a lexicon of almost 21,000 common names of American snakes, in more than 350 different modern and indigenous languages and dialects. These names are keyed to scientific nomenclature. Data in this huge file are extracted into several smaller subfiles that make their access much simpler. The lexicon is a remarkable document, winnowed from the literature, from personal communications from native speakers, and from the author's personal experiences. I am familiar with the Guaraní names for Paraguayan snakes; Tipton did not miss any that I know of, and he had several unfamiliar ones.

Another file on the CD is Tipton's working file that served as a basis for the hardcover checklist. It lists the American snake taxa to subspecies, the author and date of the name, and the countries in which the taxon occurs. For Latin America south of México, this in effect updates the checklist of Peters and Orejas-Miranda (1970; revised by Vanzolini, 1986).

The book is an exhaustively annotated checklist of American forms to subspecies, with scientific names for all taxa below the Order Serpentes, including authorities for the names, common English names, citations to much of the recent taxonomic literature, range descriptions, and remarks where the author encountered conflicting opinions. The style is that of the partial checklist of McDiarmid et al. (1999), with elements of the Peters and Orejas-Miranda (1970) Latin American synthesis. A section of *incerta sedis* contains 33 snake names that Tipton and other authors have been unable to allocate to currently recognized species. Finally, there is an 81-page bibliography, covering much of the taxonomic literature of New World snakes.

I am not a fan of invented common names. For starters, Tipton used the common names in Crother et al. (2000, 2003) for American species north of México, Liner (1994) for Mexican species, and Frank and Ramus (1995) for Central and South America. Where gaps occurred in these lists, Tipton coined new "recommended" common names. Inventing common names in an unfamiliar language can have confusing and even ludicrous results. For example, Tipton, following Liner, recommended the Spanish name "Culebra Palanaria de Sonora" for *Chionactis palarostris*. "*Palanaria*" is a frequent corruption in several languages of the flatworm genus *Planaria*. I doubt if a desert-dwelling sand snake has much to do with an aquatic worm. Delving further, we see that Tipton (and Liner) often use a translation of the Latin name for constructing a common name, and apparently *palanaria* is simply a misspelling of the Spanish *pala nariz*. This translates loosely as shovel-nosed, and is a direct translation of the Latin *palarostris*. There is another problem, however. *Nariz* is reserved for noses on humans; noses (and snouts) of animals are *hocicos*.

Trained in biophysics, Bob Tipton is, in his own words, an amateur, or serious novice, in the field of snake systematics. Recognizing this deficiency in his background, he became a protégé of one of the best: Jim Dixon of Texas A & M University. He also sought help from a long list of recognized authorities on problematic genera: Dixon for many genera; Hussam Zaher for *Oxybelis*, *Boiruna*, and *Clelia*; Robert Henderson for *Corallus*; Van Wallach for the Scolecophidia, etc.

However, the final result is uniquely Tipton. His lack of formal training shows through in many of his remarks, inconsistencies, and confused interpretations of taxonomic practice and content. For example, on page 3, the term "basal Alethinophidia" is a synonym of Haenophidia (or Henophidia elsewhere) "which are the Pythons and Boas." On page 8, "basal Alethinophidia" is a synonym of Macrostomata, which Tipton says, incorrectly, includes pipesnakes, boas and pythons. On pages 37–38, the term Haenophidia is dropped from the formal classification in favor of "Primitive (or BASAL) ALETHINOPHIDIA," which now includes only the Aniliidae. All other modern snakes, except Scolecophidians, are Macrostomatans, divided into basal Macrostomatans (Bolyeriidae, Tropidophiidae, Boidae, Pythonidae) and Caenophidia (all of the rest).

Reliance on non-peer reviewed publications, the opinions of amateurs, and the intrinsic problems in defining subspecies occasionally leads Tipton into a morass such as the mish-mash of "subspecies" of *Lichanura trivirgata* that have broadly overlapping geographic ranges.

The bibliography is one of the best parts of the book. The references appear to be accurate as far as they go, but key works are missed and secondary sources are often cited. In an especially personal example, Tipton credits a personal communication and the Smith and Smith (1993) checklist for synonymizing *Exelencophis nelsoni* and *Geatractus tecpanecus* with *Tropidodipsas annulifera*. However, this was done in Scott (1967), which is not in the bibliography. How many other, similar cases there are I can only guess.

Krieger Publishing and Tipton share responsibility for what is perhaps the most disturbing aspect of the book; it is replete with errors, both orthographic and factual. Some errors clearly predate the final editorial process, e.g., *Enicagnethus melanoauchen* [sic] for *Enicognathus melanauchen* (page 346) and the unjustified emendation of *Philodryas chamissonis* to *P. chamissona* in a misguided attempt to turn a Greek genitive ending into a feminine Latin nominative (page 201). These and other errors will have to be acknowledged in synonymies from now on.

The final editing was also incompetent. An especially egregious example is three spelling errors in a single phrase "sharing the punitive [sic] synapomorphy of a deeply bilobate hemipene [sic] and other characteristics of unknown polaritization [sic]" (page 343). Suffice it to say that I cannot remember a herpetological work, produced in the USA, with so many errors. It is a shame that the contents of the book do not live up to the excellent presentation and binding.

In summary, professionals and amateurs using the checklist need to check constantly to be sure that what they read is accurate. Tipton's book can be likened to a goldmine. There is much of value in it, but it must be selectively mined, and the resultant ore refined by experienced professionals.

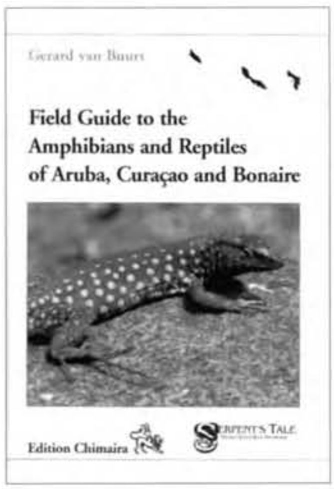
JAMES LAZELL
The Conservation Agency, 6 Swinburne Street
Jamestown, Rhode Island 02835-1414, USA
e-mail: hq@theconservationagency.org



The Netherlands Antilles ("Dutch Caribbean") consist of two remote clusters of three major islands each that could hardly be more different and still fit in the same sea. These two books mirror and surpass that degree of difference.

The first published, van Buurt's *Field Guide*, is about the South American coastal islands of Aruba, Curaçao, and Bonaire (often called the ABC islands or Dutch Leewards) with a collective herpetofauna of 26 native or established exotic species (not counting marine turtles) of largely continental relationships. There is only one native amphibian, the leptodactylid *Pleurodema brachyops*, which will convince anyone of the close relationship of its family to Bufonidae. All the endemics are reptiles: The geckos *Phyllodactylus martini* on Curaçao and Bonaire and *P. julieni* on Aruba, the anoles *Anolis bonairensis* on Bonaire and *A. lineatus* on Aruba and Curaçao, the teiids *Cnemidophorus arubensis* on Aruba and *C. murinus* with geographic variants on all three islands, and the snakes *Leptodeira bakeri* on Aruba (and possibly the proximate mainland peninsula of Paraguana, Venezuela), *Liophis triscalis* on Curaçao, and—most celebrated of all—*Crotalus unicolor*, the rattler of Aruba.

In the preface van Buurt explains that this book began as an

English translation of a previously published Dutch version (not cited and not seen by me), but with extensive upgrading and revision. Still the text would have benefited dramatically from editing by someone schooled in grammar and spelling whose first language was English. Commas appear almost randomly scattered but are conspicuously absent from some places where needed. Novel spellings include "Carribean" (p. 79), the indecisive San "Nicolaas" or "Nicolas" (p. 90), "Cricetidaea" for the rodent family Cricetidae (p. 118) that most of us now subsume into Muridae, and the snake "fer the lance" (p. 114). In fairness, however, these errors are minor and do not seriously detract from comprehension.

The text begins with a discourse on paleogeography going back to Pangaea that is out-of-date. Recent work by Christopher Scotese presented in Lomolino and Heaney (2004) shows that there never was a "Laurasia." The Tethys seaway split Eurasia from North America and the latter remained attached to Gondwana for millions of years before a protocaribbean seaway opened. This ancient history, however, can have little to do with biogeography of living vertebrates. The notion suggested by van Buurt that iguanas date from Gondwanan unity does not fit with the evidence that their radiation is about 12 million years old (Hedges 2001).

A more troubling allusion to plate tectonics appears in a long (pp. 78–80) aside bracketed into the account of *Anolis bonairensis*. Here van Buurt dusts off the idea of the Dominica/Martinique tectonic juxtaposition put forth by Roughgarden (1995) to explain the Lesser Antillean relationship of *Anolis bonairensis* and the South American relationship of *Cnemidophorus vanzoi*. Perry and Lazell (1997) reviewed the geological evidence cited by Roughgarden and asserted that it had been catastrophically misunderstood: no evidence exists for that tectonic theory. Perhaps Perry and Lazell (1997) were wrong, but no one should assume that without checking the data and the geological texts.

The remainder of van Buurt's lengthy biogeographic discourse supports waif dispersal with good, if anecdotal, evidence. Elsewhere, however, he asserts that anurans are virtually unable to disperse across sea water (p. 19) and that the gecko *Hemidactylus mabouia* "does not seem to have a natural habitat in the New World" (p. 59). Many anuran clades have dispersed across sea water, not just in the Antilles, but all the way to the Seychelles in mid-Indian Ocean and *H. mabouia* is frequent on native trees in the Virgin Islands (Lazell 2005).

There is an interesting discussion of herbivory in lizards detailing the remarkable situation of the *Cnemidophorus* in these islands: small to midsize, largely herbivorous species. However extensive evidence of facultative herbivory in other small lizards like anoles (e.g., Lazell and Mitchell 1998) was not noted. Conversely, the assertion that "The adult green iguana is fully herbivorous" (p. 67) cannot possibly apply to Lesser Antillean populations (Lazell 1973) that are aggressive, facultative carnivores whenever possible. While on *Iguana iguana*, I note van Buurt believes all Virgin Islands populations were "probably introduced" but Iverson (1980) documented distinctive *Cyclura*-like gut anatomy in the original St. Croix population. Indeed, van Buurt's evidence from the islands he chronicles argues for great evolutionary diversity within *I. iguana*.

In the discussion of the introduced toad *Bufo marinus* van Buurt points out the potentially devastating effects this poisonous species might have on native predators. He also documents with photos (66, 67) a snake, *Lepidoptera bakeri*, consuming one, but does not report on the fate of the snake. Readers should also note that, technically, the toad's toxin is not a "venom" because it is not injected. Bits like this highlight the lack of a glossary which is needed for various terms used.

Generally, this is a solid guide with lots of interesting information and mostly good (some great) photos. I could wish for more detail on differences between closely related species, such as the geckos in *Phyllodactylus* and *Gonatodes*, and more information generally on a rarity like the lizard *Tretioscincus bifasciatus*, for which van Buurt seems to lack first hand information and shows only 70-year-old, very grainy, black-and-white photos.

In these respects this book tells us what we need to discover more about: a very useful and stimulating tool.

The volume by Powell et al. is a sort of natural history monograph loaded with technical detail (with terms defined in the text and a glossary). There are accounts of 25 species (including three marine turtles) four of which are established introductions: blind snake (*Typhlops* or "*Ramphotyphlops*" *braminus*), slider turtle (*Trachemys scripta*), whistling frog (*Eleutherodactylus johnstonei*), and Cuban treefrog (*Hyla* or "*Osteopilus*" *septentrionalis*). The latter two are the only anurans, so there are no native amphibians. Strictly speaking, there is only one endemic reptile, the Saba Anole, *Anolis sabanus*. This is an artifact produced by colonial history and resulting political boundaries: the three major islands—Saba, St. Eustatius, and St. Maarten—are on three separate oceanic banks (that were separate, larger land areas at glacial maximum). Were one to score endemic species on these banks there would be 11 more: the Red-faced Ground Lizard (*Ameiva erythrocephala*), Anguilla Bank Ground Lizard (*A. plei*), St. Kitts Bank Tree Anole (*Anolis bimaculatus*), Anguilla Bank Tree Anole (*A. gingivinus*), St. Maarten Bush Anole (*A. pogus*), the St. Kitts Bank Bush Anole (*A. schwartzi*), Anguilla Bank Dwarf Gecko (*Sphaerodactylus parvus*), Saba Dwarf Gecko (*S. sabanus*), Island Dwarf Gecko (*S. sputator*) Anguilla Bank Racer (*Alsophis rijgersmaei*), and Red-bellied Racer (*A. rufiventris*). Thus more than half the native herpetofauna is endemic to the banks with Dutch islands on them.

Powell et al. provide a lengthy discussion of conservation efforts and descriptions of conservation organizations active in these islands. Each species account also includes a section on conservation status. Two species, a skink (*Mabuya* sp. indet.) and the Anguilla Bank Racer, have apparently been extirpated from the Dutch islands (both from St. Maarten) but survive elsewhere. The native population of *Iguana delicatissima* also seems to be gone from St. Maarten, replaced by introduced *I. iguana*. Within *I. iguana*, Powell et al. make a strong case for the distinctiveness of the Saba population or form, but it was seriously reduced by human predation for food (a supposed aphrodisiac) a couple of decades ago, and may now be even more threatened by introduced pet trade *I. iguana*. Indeed introgression with exotic *I. iguana* threatens not only the genetic integrity of native *I. iguana* populations but the very survival of *I. delicatissima*.

Every species account in this book includes — in addition to fundamental description, distribution, and natural history data — sections on food, predators, reproduction, behavior, and conservation. Thus, this is far more than a field guide. The photographs are mostly excellent, although some are difficult to decipher (e.g.,

the lower of fig. 150; hint: search for the banded tail). Powell et al. weakly back me up on natural habitats for *Hemidactylus mabouia* (p. 110) but also say things like "Iguanas of all ages are almost exclusively herbivorous" (p. 65); they fess up to the truth occasionally: "... bird eggs and even carrion" (p. 66), "... bird eggs and carrion" (p. 73), and: "Young iguanas... will consume insects and other small animals..." (p. 61) [whenever they get the chance, believe me].

In addition to the regular eight headings in each species account, there may be an additional comment. That for the skink *Mabuya* is especially appealing to me because I believe considerable evolutionary diversity is going unrecognized in these lizards. In addition, many populations, as the authors note, are apparently declining and some have been extirpated before we got them sorted out.

The only account with which I have real problems is for the Asian exotic blind snake *Typhlops* or "*Ramphotyphlops*" *braminus*. The genus "*Ramphotyphlops*" is defined solely on the basis of male hemipenial structure and this species consists entirely of parthenogenetic females. Furthermore, these snakes frequently produce live young although they can also lay eggs (Lazell 2002 and references therein). Lastly, this blindsnake is not confined to the tropics but has apparently established populations as far north as Virginia and even Massachusetts (Savitsky et al. 2002 and references therein).

While a third longer than van Buurt's book, that of Powell et al. is short and compact enough to function as a field guide. The pages are plasticized; this makes for excellent photographic presentation and is water and mildew proof. However, the pages stick together infuriatingly and are very stiff. My copy is already breaking up at the binding and soon will be a bundle of cards. Much more than a field guide, Powell et al. is a virtual introduction to herpetology using the species of this little island cluster as examples. I can strongly recommend Powell et al. as a densely fact-packed good read on geology, geography, conservation, and natural history in general.

A New Facsimile Reprint from the Society for the Study of Amphibians and Reptiles in Cooperation with the Societas Herpetologica Italica

THE LIFE AND HERPETOLOGICAL CONTRIBUTIONS OF MARIO GIACINTO PERACCA (1861-1923)

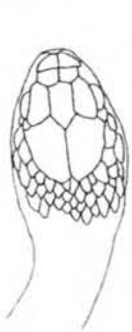
WITH AN INTRODUCTION, ANNOTATED BIBLIOGRAPHY AND SYNOPSIS OF TAXA BY FRANCO ANDREONE AND ELENA GAVETTI

Mario Peracca (1861–1923) was one of the foremost Italian herpetologists of the late 19th and early 20th centuries. Although poorly known today in comparison to some of his contemporaries, Peracca published numerous faunal works, many including descriptions, based on the collections that reached the Turin Museum from the expeditions of Fea, Festa, Borelli and others. In addition, he collected within Italy himself, describing the salamander *Molge italica* (now *Triturus italicus*). He was also a pioneer of reptile husbandry, keeping a great diversity of species, including the tuatara, *Sphenodon punctatus*, and the now extinct skink *Macroscincus coctaei* in specially built enclosures at his villa in Chivasso, outside Turin. Although much of Peracca's work with captive animals remained unpublished, some of his observations formed the basis for papers on reproduction and behavior.

Among his faunal works, Peracca is perhaps best remembered for his papers on Madagascar and South America, although he also published on African and Asian taxa. Peracca published 64 scientific papers over the period 1882–1917. The majority of the papers are in Italian, with a few in English, French and German; all are included in facsimile in this SSAR volume. Peracca described 22 amphibian species (14 still valid) representing the families Bufonidae, Dendrobatidae, Hylidae, Leptodactylidae, Microhylidae, Pipidae, Mantellidae and Ranidae, and 52 reptiles (26 currently valid) in the Anguidae, Gekkonidae, Gymnophthalmidae, Hoplocercidae, Lacertidae, Polychrotidae, Scincidae, Teidae, Tropiduridae, Amphisbaenidae, Colubridae, Elapidae, Tropidophiidae, Typhlopidae and Viperidae.

An introduction by Franco Andreone and Elena Gavetti provides a biography of Peracca, a summary of all of the herpetological names he proposed, and an annotated bibliography. The biography uses archival copies of Peracca's correspondence to highlight his long association with G.A. Boulenger, whom he considered as his herpetological mentor, and to reveal a never-realized plan with Albert Günther to introduce tuataras onto small islands in the Mediterranean. Peracca spent his fortune in support of charity and of his private live animal research interests and died in bankruptcy.

Specifications: 550 pages, 6 x 9 inches, clothbound. ISBN 0–916984–69–9. To be published September 2006.



PRICES AND SHIPPING COSTS: $55 ($45 to SSAR and SHI members for orders received before 1 September 2006) • *Shipping*: USA address, add $4; non-USA add $9.

SEND ORDERS TO: Breck Bartholomew, P.O. Box 58517, Salt Lake City, Utah 84158-0517, USA (*telephone*: 801-453-0489; *fax*: 801-562-2660; *e-mail*: ssar@herplit.com). Orders may also be charged to American Express, Discover, MasterCard or VISA (Please provide the account number and card expiration date). SSAR membership information and a complete list of all Society publications can be obtained on request to Mr. Bartholomew.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address). To submit a manuscript to ***HR***, please consult the SSAR webpage at:

<http://www.ssarherps.org/pages/HRinfo.html>

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution or Natural History notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order form will be sent prior to publication. These are also available upon request from the Editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR Treasurer (Dr. Theodora Pinou; contact information below) or from the SSAR web page (http://www.ssarherps.org/pdf/Adrates.pdf).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Peabody Museum of Natural History, Yale University, P.O. Box 208118, New Haven, Connecticut 06520-8118, USA. Periodical postage rates are paid at New Haven, Connecticut with additional entry offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Attn. Dr. Theodora Pinou, SSAR Treasurer, Western Connecticut State University, Department of Biological & Environmental Sciences, 181 White Street, Danbury, Connecticut 06810, USA. Please notify Breck Bartholomew, SSAR Publications Secretary (contact information below), regarding missing or damaged issues.

SSAR Publications

SSAR publishes seven different series: *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Contributions to Herpetology, Herpetological Circulars, Herpetological Conservation*, and the *Catalogue of American Amphibians and Reptiles* (see below for CAAR details). SSAR members receive pre-publication discounts on all *Facsimiles* and *Circulars* and on volumes in the *Contributions* and *Herpetological Conservation* series. A complete pricelist of Society publications is available at: <http://www.herplit.com/SSAR/>

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 37, Number 1 (March 2006).

CAUDATA

AMBYSTOMA MACULATUM (Spotted Salamander). **MORTALITY**. *Ambystoma maculatum* are winter breeders in the southeastern United States. Individuals are often subjected to unpredictable environmental conditions, such as partial freezing of aquatic habitats, during their breeding activities. Adult mortality from partial freezing of aquatic habitat is known (Harris 1980. Copeia 1980:719–722), but has rarely been described. We report here on observations of *A. maculatum* mortality during reproduction after a partial freeze of a wetland in Mecklenburg County, North Carolina, USA during the winter of 2005.

Warm air temperatures (up to 20°C) and precipitation from 25–27 January proceeded and apparently initiated *A. maculatum* breeding activity. On 28 January, a cold front moved through the area and maximum air temperatures remained below freezing (-6°C) until 30 January. A thin (< 2 cm) layer of ice formed over the majority of the wetland, and remained until 8 February. We surveyed the wetland between 2–10 February 2005 and observed 27 dead *A. maculatum*; 21 females (mean SVL = 103.6 mm, SD = 3.82 mm; TTL = 192.3 ± 7.25 mm; N = 19), and 6 males (mean SVL = 99.2 ± 12.77 mm; TTL = 190.33 ± 28.12 mm). Seventeen of the females contained eggs (mean = 65.47 ± 48.59; range 11–182). Nine individuals had various body injuries such as missing pieces of the head and torso, or punctures in the ventral side. We also collected dead individuals of *Rana sphenocephala* (3), *R. catesbeiana* (2), *Pseudacris ferairum* (1), *Acris crepitans* (1), and *Chrysemys picta* (1).

Our observations confirm those of Harris (1980, *op. cit.*), which suggest that freezing of aquatic habitats can lead to mortality in *A. maculatum*, and that mortality is skewed towards females, even though males are often more numerous in breeding ponds (Stenhouse 1985. Copeia 1985:631-637). The reason females are more susceptible than males to freezing is unknown, however, we speculate it might be the result of egg-depositing behavior, sensitivity to reduced oxygen levels, or the reluctance to leave the wetland when gravid. Although we did find several individuals with injuries, we believe it is likely these injuries were induced post-mortem by aquatic invertebrates or other scavengers inhabiting the wetland. This research was supported by the Davidson College Department of Biology, Duke Power and National Science Foundation grant (DEB – 0347326) to MED.

Submitted by **YURII V. KORNILEV**, **STEVEN J. PRICE**, **EMORY P. HILL**, and **MICHAEL E. DORCAS**, Department of Biology, Davidson College, Davidson, North Carolina 28035-7118, USA (e-mail [SJP]: sjprice@davidson.edu).

AMBYSTOMA TALPOIDEUM (Mole Salamander). **DIET**. On 18 March 2003, JGP removed a drowned terrestrial morph adult female *Ambystoma talpoideum* (51.5 mm SVL) from a plastic minnow trap set in a 0.3 ha seasonal wetland on Moody Air Force Base, Lowndes County, Georgia, USA. Upon dissection, the following aquatic invertebrates were removed from the salamander's stomach: nine clam shrimp (Lynceidae: *Lynceus*), three isopods (Asellidae: *Caecidotea*), two unidentifiable mosquitoes (one larva, one pupa; Culicidae), one beetle (Dytiscidae: *Uvarus*), and one beetle larva (Dytiscidae: *Agabus*).

Previous reports of metamorphosed *A. talpoideum* adults feeding while in breeding habitats include Cliburn and Carey (1975. J. Mississippi Acad. Sci. 20:49–52) and McCallister and Trauth (1996. Southwest. Nat. 41:62–64). Conspecific ova were consumed exclusively by the specimens examined by McCallister and Trauth (*op. cit.*). In addition to unidentified amphibian ova, Cliburn and Carey (*op. cit.*) observed aquatic invertebrates in *A. talpoideum* stomachs. Collectively, these three reports of aquatic feeding by metamorphosed adult *A. talpoideum* suggest that this behavior might not be uncommon. Moreover, aquatic feeding by adults might be an important strategy to recover energy reserves expended during the breeding season.

Funding for JGP was provided by the U.S. Air Force through a contract with the Center for Reptile and Amphibian Conservation and Management, Indiana-Purdue University, Fort Wayne, Indiana. Field work by JGP was authorized by Georgia scientific collection permit # 29-WMB-02-20. We thank Greg Lee for access to MAFB and Bruce Kingsbury for administering funding.

ANEIDES AENEUS (Green Salamander). **DISPERSAL**. *Aneides aeneus* inhabits cliffs and rockface outcrops at elevations <1340 m in mountainous forests from southwestern Pennsylvania to extreme northeastern Mississippi (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington D.C. 587 pp.). Populations are largely confined to deep crevices within sandstone, granite, and schist formations but occasionally are found under loose bark of fallen trees (Petranka, *op. cit.*). The extent to which *A. aeneus* disperses between isolated rock outcrops is unknown. Individuals are rarely observed in adjacent forest floor habitats even when collecting around rock outcrops with large populations (Snyder 1991. J. Tennessee Acad. Sci. 66:165–169). Although *A. aeneus* has been recorded crossing roads during April–June (Cupp 1991. J. Tennessee Acad. Sci. 66:171–174; Williams and Gordon 1961. Copeia 1961:353), disturbance to forest habitats is thought to limit dispersal between rock outcrops (Petranka, *op. cit.*). Here we report dispersal of *A. aeneus* across an open, disturbed habitat in southern West Virginia.

On 1 October 2004 we discovered a single adult *Aneides aeneus* under an artificial coverboard in an actively grazed livestock pasture at Reba Farm (37°47'31"N, 80°58'30"W), a USDA Appalachian Farming Systems Research Center site near Beaver, Raleigh County, West Virginia, USA. All woody vegetation, coarse woody debris, and rocks had previously been removed from the pasture (884 m elev) to facilitate grazing. Natural ground cover within the pasture was limited to Orchardgrass (*Dactylis glomerata*) and

White Clover (*Trifolium repens*). The coverboard (30 cm × 46 cm × 5 cm), installed flush against the topsoil, was one of 20 white oak boards within the pasture. The coverboard was 54.9 m from the nearest rock outcrop and 45.7 m from the nearest woodland habitat. Surface temperature under the coverboard was 12.7°C. Searches of all habitat within a 150-m radius of the coverboard and all other boards within the pasture revealed no additional *A. aeneus*. Additionally, no *A. aeneus* were found when all coverboards in the pasture were re-sampled on 15 October 2004.

Although mating in West Virginia populations of *Aneides aeneus* occurs primarily during May–June, the timing of our observation coincides with a secondary breeding period that is thought to occur in September–October (Canterbury and Pauley 1994. J. Herpetol. 28:431–434). Our observation is significant as it documents dispersal of *A. aeneus* across non-forested, repeatedly disturbed habitat previously considered unsuitable for the species. Our observation also suggests the possibility that artificial cover objects might facilitate dispersal of *A. aeneus* between rock outcrops by providing suitable microenvironments or refugia within otherwise harsh, open habitats.

DESMOGNATHUS MONTICOLA (Seal Salamander). **ARBOREAL BEHAVIOR.** On 15 August 2004, ca. 1345 h, an adult male *Desmognathus monticola* was found under the bark of a Yellow Buckeye tree (*Aesculus flava*) ca. 1 m above the ground and 4 m from the water of Indian Creek, Unicoi, Unicoi County, Tennessee, USA (N36°10.572', W82°17.884'). *Desmognathus monticola* is generally associated with streams and is known to ascend wet rocky stream banks (Dodd 2004. The Amphibians of Great Smoky Mountains National Park. University of Tennessee, Knoxville. 283 pp.). Nocturnal climbing, especially during rain, has been noted for other *Desmognathus* species (Hairston 1949. Ecol. Monogr. 19[1]:47–73; Hairston 1986. Am. Nat. 127:266–291; Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington, DC. 587 pp.). However, to our knowledge, this is the first record of arboreality in this species and the first record of any *Desmognathus* using an arboreal diurnal retreat. The individual was collected under Tennessee permit number 1920 issued to Maxim Shpak and is deposited at Yale Peabody Museum of Natural History (YPM 10037).

EURYCEA CIRRIGERA (Southern Two-lined Salamander). **GILL MORPHOLOGY**. Because larval two-lined salamanders (*Eurycea bislineata* complex) typically inhabit lotic environments (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Inst. Press. Washington, D.C. 587 pp.), little is known about interdemic variation in larval morphology. Herein we report on interdemic variation in gill morphology for *E. cirrigera* larvae from southern West Virginia, USA. Larvae were collected seasonally (April 1994–January 1995) from Fitzpatrick's Branch, an intermittent, first-order stream in Cabell County, West Virginia (Brophy and Pauley 2002. Maryland Nat. 45:13–22) and Trump-Lilly Pond, a small farm pond in Raleigh County, West Virginia (Brophy and Pauley 2001. Herpetol. Rev. 32:98–99).

Captured larvae were anesthetized in chloretone, fixed in a 4% formalin solution, and preserved in 70% ethanol. The following measurements were made on the left side of each larva using a dissecting microscope and ocular micrometer: Fimbria length (FimL) – length (mm) of longest fimbria on 3rd gill arch; Fimbria width (FimW) – width (mm) midway along FimL; Rachis length (RachL) – length (mm) of rachis on 3rd gill arch; and Number of fimbriae (NumFim) – total number of fimbriae on 3rd gill arch. All characters were standardized for body size by regressing each variable against SVL and using the residuals in statistical procedures (Atchley et al. 1975. Am. Zool. 15:829; Atchley et al. 1976. Syst. Zool. 25:137–148). Larvae within each site were grouped across seasons ($N = 95$ for each site) and two-tailed Student's t-tests on the residuals were used to determine whether differences in gill morphology occurred between larvae from different habitats.

Differences in gill morphology were very apparent between larvae from pond and stream habitats. In general, pond larvae had relatively larger gills and a greater number of fimbriae than their stream counterparts. Mean values of the residuals for FimL, FimW, RachL, and NumFim were significantly different between pond and stream larvae ($p < 0.0001$ and $df = 188$ in all cases; FimL: $t = 10.01$; FimW: $t = 9.67$; RachL: $t = 9.62$; NumFim: $t = 5.78$). Mean residual values of pond larvae (positive) were greater than those of stream larvae (negative) for all gill characters. Causes of interdemic variation in gill morphology are unknown in this case, but future studies should investigate dissolved oxygen levels (Bond 1960. Dev. Biol. 2:1–20; Timmerman and Chapman 2004. J. Fish Biol. 65:635–650), temperature (Smith 1990. Ecology and Field Biology, 4th ed. Harper Collins Publ. New York), larval activity rates (McFarland et al. 1979. Vertebrate Life, 1st ed. Macmillan Publ. Co. New York. 875 pp.), and ion concentrations (Timmerman and Chapman, *op. cit.*) as potential causal factors.

We thank Michele L. Brophy, Peter A. Kramer, and James W. Barron for their assistance in the field and lab. All specimens were collected under WVDNR permit numbers 19-1994 and 52-1995, and voucher specimens were deposited in the West Virginia Biological Survey collection at Marshall University (WVBS 6879–6921). This study was partially funded by a research grant to TRB from the Marshall University Graduate Student Council.

EURYCEA CIRRIGERA (Southern Two-Lined Salamander). **COLORATION.** Herein we report a leucistic larval *Eurycea cirrigera* (24 mm SVL) collected in northern Raleigh, North Carolina, USA (35.8599°N, 78.6733°W; WGS84/NAD83) on 27 May 2004. This individual is believed to be the second observation of a leucistic *Eurycea cirrigera*. Typical larvae are gold in color with extensive dark mottling. The leucistic individual lacked most pigmentation, exhibiting a transparent, cream coloration with faint orange and light brown speckling. The individual was classified as leucistic because of the presence of brassy eyes with dark pupils, instead of the unpigmented eyes of an albino. The light coloration contrasted markedly from other normal individuals; however, similar size, development, and behavior were observed.

We believe this is the second report of a leucistic *E. cirrigera* in North Carolina or elsewhere. Review of files and reexamination of an adult female considered albinistic by Palmer and Braswell (1980. Brimleyana 3:49–52) supports calling it leucistic using current terminology (Bechtel 1995. Reptile and Amphibian Variants: Colors, Patterns, and Scales. Krieger Publ. Co., Malabar, Florida). Although the frequency of leucism is unknown, repeated sampling of 45 sites in Wake County, North Carolina, USA produced 866 observations of *E. cirrigera* larvae, including 58 observations at the site where this specimen was collected. No other leucistic individuals were observed. In addition, only one similar specimen or record of this color variant is present in the North Carolina State Museum of Natural Sciences (NCSM) collection, which documents over 9000 specimens of *E. bislineata* complex from throughout the state. The larva was believed to be one-year old at the time of collection and was lab reared through October of 2004 without metamorphosing. The individual is catalogued as NCSM 66443.

ANURA

ATELOGNATHUS PATAGONICUS (NCN). **DIET**. Within the life history of a species, knowledge of its trophic habits is essential to draft a conservation strategy. *Atelognathus patagonicus* is an aquatic frog endemic to the endorheic pond system in Laguna Blanca National Park and the surrounding area in northwest Patagonia, Argentina (Cei and Roig 1968. Physis 27:265–284; Gallardo 1962. Neotropica 8:45–68). It is categorized as "Endangered" (IUCN, Conservation International, and Nature Serve. 2004. Global Amphibian Assessment. <www.globalamphibians.org>. 13 Dec 2004). Two forms of *A. patagonicus* have been recognized: "aquatic" and "littoral" (Cei and Roig 1968, *op. cit.*). The "aquatic form" has large interdigital membranes and highly developed cutaneous folds on its trunk and thighs. The "littoral form" lacks these features. The "aquatic form" makes up the largest part of the population, and lives under submerged rocks. The "littoral form" lives out of the water, some distance away from the ponds. The species has disappeared from the largest body of water in the system (Laguna Blanca, 1780 ha), and is currently restricted to 15 bodies of water smaller than 60 ha (Cuello, unpubl. data). The disappearance of *A. patagonicus* from Laguna Blanca has been linked to the introduction of *Percichthys colhuapiensis* (Perca) and salmonids in the mid-1960s. These species rapidly colonize ponds and feed on a variety of aquatic organisms (Ferriz 1989. Iheringia 69:109–116; Macchi et al. 1999. Ecol. Freshw. Fish 8:227–236). Here we report the first qualitative and quantitative data on the diet of the "aquatic form" *A. patagonicus*.

The study was conducted during the austral summer (January 2001) in Laguna del Hoyo (39°00'36"S, 70°25'48"W; ca. 1400 m elev.), a permanent pond in Laguna Blanca National Park. This pond has a surface area of 38 ha, and a perimeter of 2.69 km, 40% of which is rocky, providing an optimal habitat for the frog. A large variety of aquatic arthropods, mainly amphipods, thrive under the rocks. The rooted macrophyte *Miriophyllum quitense*, colonial Nostocaceae algae and filamentous algae are well-developed in the pond. Nine "aquatic form" *A. patagonicus* were captured by hand, immediately euthanized, and fixed in 10% formalin. Body length ranged from 27.1–40.5 mm. Mean body length was 33.4 ± 2.5 mm for males (N = 5) and 33.55 ± 2.1 mm for females (N = 4). The diet was analyzed by examining the digestive tracts (stomach–small intestine). Prey was identified to the lowest possible taxonomic level. The individual volume of each prey item and the number of prey items per digestive tract for each prey category were recorded. Frequency of occurrence of each taxon was calculated as number of digestive tracts in which a certain taxon was found, divided by total number of digestive tracts examined. The large intestine was analyzed qualitatively to obtain additional information.

The diet of the "aquatic form" of *A. patagonicus* was made up of aquatic organisms of phylum Arthropoda. The food consisted of three prey categories found in the stomach-small intestine and two additional prey categories found in the large intestine. The diet was dominated numerically and volumetrically by amphipods of the genus *Hyalella* (87.7% and 92.2%, respectively). *Hyalella* was the most frequent prey, found in 100% of the frogs. Additional prey categories found in the large intestine were caterpillars and insect eggs. From 2 to 19 prey items were found per frog. Size ranged from 2 to 12 mm. The mean length of prey body was 8.1 ± 7.1 mm and the mode was 7 mm. Medium-sized prey was the most numerous and consisted almost exclusively of *Hyalella*. The diet of the larger frogs had the widest range of prey size and the greatest number of food categories. Coleoptera and Hemiptera made up a secondary food source.

The feeding pattern of *Atelognathus patagonicus* "aquatic form" is a consequence of the microhabitat where it lives. Shallow water with a high density of aquatic vegetation, where invertebrate richness is usually high, enables food selection. As a result of our observations, we speculate that the frog shows prey selection, suggested by its high consumption of amphipods. We have noted that frogs in ponds adjacent to Laguna del Hoyo tend to feed on amphipods. Furthermore, from unpublished data available for comparison (Mazzuchelli 1991. Informe Final del Programa Relevamiento preliminar de las comunidades acuáticas del Parque Nacional Laguna Blanca, Unpubl. Report to Administración de Parques Nacionales. Delegación Técnica Regional Patagónica, San Carlos de Bariloche, Argentina. 13 pp.) we know that amphipods were the dominant food item in Perca diet in the early 1990s in

Laguna Blanca, where *A. patagonicus* is now extinct. This suggests that both frogs and Percas may have shared the amphipod resource in the pond.

The information on the feeding habits of *A. patagonicus* presented here is part of an investigation of the interaction between frogs and introduced fish. There is a need to preserve the essential trophic resource for the "aquatic form" of the frog species, and strict official control should prevent any further introduction of fish into these ponds.

BUFO CALIFORNICUS (Arroyo Toad). **MORTALITY.** On 14 May 2001, in a dry arroyo along a secondary channel of San Ysabel Creek (San Pasqual Valley, San Diego County, California, USA: N33.05.396, W116.58.164, WGS 84) DAK found a freshly-crushed toad carcass pressed into the sand within a tire track of a utility quad (off highway-vehicle [OHV]). The specimen was collected and brought to ELE and RNF for identification. The amphibian was subsequently identified as the federally endangered *Bufo californicus* [42 mm, snout–urostyle length [SUL]: SDSNH 69059]. The body of the toad was vertically compressed with a skin abrasion on the ventral surface and a partially protruding tongue. Based on the injuries sustained we concluded that the cause of death was crushing due to vertical pressure, most likely sustained from the force of impact from the OHV tires. It is unclear whether the toad was run over while on the surface (e.g., foraging) or burrowed under the sand and subsequently writhed to the surface. As evidenced by the abundance of tire tracks along the braided channels and across the sandy upland terraces, the habitat on private and public lands of San Ysabel Creek in San Pasqual Valley (ca. 5.5 × 0.75 km) is subject to intensive use by OHV riders (pers. obs.).

The reach of San Ysabel Creek where the dead specimen was collected supports a large population of *B. californicus* (U.S. Fish and Wildlife Service 1999. Arroyo Southwestern Toad [*Bufo microscaphus californicus*] Recovery Plan. USFWS, Portland, Oregon 119 pp.; pers. obs.). Documentation of this crushed individual demonstrates the vulnerability of this endangered species to incompatible recreational activities within occupied habitats.

Our thanks to Mark R. Jennings for making useful suggestions, which improved the manuscript, and to Dustin Wood of San Diego Natural History Museum for providing us with the specimen number.

BUFO HOUSTONENSIS (Houston Toad). **JUVENILE DISPERSAL.** *Bufo houstonensis* is an endangered anuran endemic to central-east Texas. Although its breeding behavior has been well documented (Hillis et al. 1984. J. Herpetol. 18:56–72; Price 2003. TPWD report 03-0401), the little published information concerning the juvenile life stages focuses mainly on predation (Freed and Neitman 1988. Texas J. Sci. 40:454–456), coloration (Mays and Freed 1985. Herpetol. Rev. 16:108–109), and growth (Greuter and Forstner 2003. Herpetol. Rev. 34:355–356; Quinn and Mengden 1984 Southwest. Nat. 29:189–195).

A *Bufo houstonensis* egg string was surrounded with an aluminum flashing enclosure during Spring 2004 at the Griffith League Ranch (GLR) in Bastrop County, Texas, USA to monitor post-metamorphic behavior. Upon emergence, 993 individuals were captured and a single toe was clipped to identify the cohort year. The flashing was removed and 100 individuals were dusted with inert fluorescent powder (Radiant Color, T1 pigment) and released as a single group at the point of emergence. Fluorescent pigment was successfully used to track adult *Pelobates fuscus* (Eggert 2002. Herpetol. J. 12:69–74) and the same technique was applied in tracking juvenile *B. houstonensis* dispersal. Toadlets were monitored immediately following release to determine if the pigment caused any malaise, and normal activity was observed. Metamorphs were located with a UV light (Raytech, Raytector–V Portable UV Light) for two consecutive nights and observed during the early morning hours of the day following their pigment-marked release. Metamorph locations were marked with marking flags; the area was left as undisturbed as possible, and the dispersal pattern was not analyzed until after the metamorphs left the pond's edge. It was our intention to follow the juveniles for a longer period, but during the afternoon of the third day, GLR received over 25 mm of rain. We believe this resulted in the pigment powder washing off of the toads as well as washing away trackways from the preceding night's dispersal.

We released the pigment-marked individuals at the point of emergence at the pond's edge. The tracks from individual metamorphs were not distinguishable within 0.5 m of the release site because of the large amount of powder deposited in a small area. However, tracks could easily be distinguished beyond the initial confused area of powder marks. When dispersing from the pond's edge metamorphs did not move in a straight line, but in a seeming random pattern that may have been foraging or shade seeking behavior. The majority of the pigment-marked individuals retreated into the water after release, which is normal behavior for post-metamorphic *B. houstonensis* (Greuter 2003. Unpubl. MS. Thesis, Texas State Univ. San Marcos, Texas. 80 pp.). We were able to track 15 individuals over two days. Within 48 h after emergence, 8 of the *B. houstonensis* metamorphs had dispersed at least 4 m from the pond's edge. Mean dispersal distance was 3.24 m (range 0.7–5.13 m; median distance 3.43 m; N = 15) from the release point. The majority of the individuals (N = 12) were found buried under grass or sedge tussocks. The dispersal pattern did not increase in diameter from 24–48 h after marking. After the rainfall event, no pigment-marked metamorphs were relocated, however, toe-clipped individuals were quickly located, so we assumed the pigment washed off during the rainfall.

During this study, metamorphs did not show any ill effects related to the powder. Using this method was an easy, efficient, and

cost effective way to track post-metamorphic juveniles. Nighttime observations of the movements of pigment-marked juveniles were easily monitored using UV light. Metamorphs were also observable during the day as the powder is highly visible, allowing us to observe toadlets without disrupting the point of emergence. We could visually track the individuals during day using binoculars from a distance of 3 m without difficulty. This is particularly relevant given the concentration of individuals at the pond's edge during the emergence period and the consequent care required to prevent accidental mortalities when trying to observe the behavior of these juveniles. We did not observe direct foraging during day or night surveys. Individuals appeared to be moving between shaded cover (daylight) or moving from one resting area to the next (night time). The technique does have an inherent weakness in very wet or rainy areas.

This study was conducted under permits issued to MRJF (USFWS: TE039544-1, TPWD: SPR-0102-191, and TXSTATE-IACUC: HGVMAD_02 and 5Qrs45_02).

BUFO SPINULOSUS PAPILLOSUS (NCN). **REPRODUCTION**. Information on the reproductive biology of the Patagonian toad *Bufo spinulosus papillosus* is scarce. Species of the genus *Bufo* lay eggs in large clutches and are explosive breeders (Wilbur 1987. Ecology 68:1437–1452). Their eggs are typically laid in strings (Zug et al. 2001. Herpetology: An Introductory Biology of Amphibians and Reptiles. 2nd ed. Academic Press, San Diego, California. 630 pp.). This note provides the first description of the clutch characteristics, egg-laying site, and breeding season of *Bufo spinulosus papillosus* in northwest Patagonia, Argentina. *Bufo spinulosus papillosus* is distributed over the Andean and extra-Andean Patagonia in Argentina and Chile (Cei 1980. Amphibians of Argentina. Monit. zool. ital. [N.S.], Monogr. 2:[i-xii] + 1–609), and is found at altitudes of up to 2000 m (Úbeda, pers. obs.). It inhabits both the open steppe and temperate austral forests and their ecotones (Cei, *op. cit.*). It is common in rivers, streams, and steppe wetlands (*mallines*), and in open areas in the forest, such as lake and river shorelines (Christie 1998. Patagonia Silvestre [Ser.Tec.] 2:27–32).

Bufo spinulosus papillosus populations were studied at two localities. Locality 1 comprises a pond and a collateral arm of a stream, surrounded by semi-xeric thicket (41°10'52"S, 71°19'14"W; 906 m elev.). Locality 2 is a temporary pool located on a river floodplain surrounded by humid *Nothofagus* forest (41°13'52"S; 71°46'17"W; 850 m elev.). Observations were made during austral springs (September–December) from 2001 to 2004. Clutch sites (temperature, depth, substrate, and vegetation) and breeding timing were studied and compared at both localities. Clutch description was based on material from Locality 1. In the field, the duration of embryonic development was recorded for one clutch up to the time of hatching. Total length was measured for 4 clutches, from which segments were collected and preserved in 10% formalin. In the lab, segment length was measured and the number of eggs counted to obtain an estimate, by extrapolation, of the total number of eggs. String and egg diameters were also measured, and colouring described. In addition, 3 clutches were incubated to determine larval stage at hatching (Gosner 1960. Herpetologica 16:183–190). To verify species identity, these larvae were monitored until metamorphosis was complete.

Bufo spinulosus papillosus has a seasonal breeding pattern. It begins oviposition in early austral spring, acting as an early breeder. At Locality 1, a total 39 clutches were recorded (15, 1, 13, and 10 during the years 2001–2004). All eggs were laid from the last week in September to the first week in October, over a period of 4–7 days, except in 2002, when there was a delayed spring, and only one clutch was laid in the first week of November. In contrast, at Locality 2, five reproductive events were recorded from early austral spring to summer (October–December 2001). Although Locality 1 has two environments (pond and stream), which offer different microenvironments, the clutches were all laid in shallow zones (4.08 ± 1.52 cm deep, range 2–8 cm deep, N = 13), with very little or no current, little or no vegetation, on a substrate of silt or pebbles and cobbles. Water temperatures at the clutch sites in the pond in September 2003 were 9.7 ± 1.78°C at 0900 h, and 23.22 ± 4.08°C at 1500 h. Eleven clutches were found along 10 m of pond shoreline, located relatively close to each other (from 5 cm to 2 m apart), averaging 1.25 clutches per linear meter along the shore. Clutches are laid in strings of variable length (from 4–6 m) and very uniform diameter (minimum 8.3 mm), which become increasingly hydrated in contact with water (up to 17.3 mm). Clutches contained from 3250 to 6400 eggs (4480 ± 1348 eggs, N = 4), which are arranged alternately in two rows in the string. Egg diameter is 1.56 ± 0.09 mm (N = 104), and the coloring is dark brown, almost black at the animal hemisphere, fading gradually towards the vegetal pole, which is creamy pale grey. Under natural conditions, tadpoles hatched 4 days after the eggs are laid. Newly hatched tadpoles stay at the bottom of the water body, near the remains of the string. In the lab, they hatched at stage Gosner Stage 18–19 when muscular contraction begins.

The seasonal breeding pattern of *Bufo spinulosus papillosus* matches that of most anuran species in temperate regions of the world (Duellman and Trueb 1986. Biology of Amphibians. McGraw-Hill Book Co., New York. 610 pp.). Like other species of the genus, *B. s. papillosus* has several adaptations to accelerate embryonic and larval development, such as clutches laid in shallow, sunny sites, and highly melanized eggs laid in a gelatinous string which is presumed to have insulating properties. The presence of melanin and the gelatinous string also provide protection against ultraviolet radiation. These characteristics, plus a short larval period, are advantageous for exploiting temporary environments. Regarding the range of clutch size, it may depend on the body size of the females (maximum SVL 10 cm), as has been shown for other anurans (Duellman and Trueb, *op. cit.*). The two breeding strategies (explosive and prolonged), found at the two localities studied, have also been reported for some other *Bufo* species (Wagner and Sullivan 1992. Copeia 1992:647–658). The different strategies found in this study could be related to the difference in spring rainfall (October –December) between localities (100–150 mm at Locality 1 and 400–500 mm at Locality 2). Further studies are needed on the subspecies' breeding behavior prior to egg-laying.

BUFO SPINULOSUS PAPILLOSUS (NCN). **TADPOLE BEHAVIOR**. Gregarious tadpole behavior has been described for several anuran species (Wassersug 1973. *In* Vial [ed], Evolutionary Biology of the Anurans: Contemporary Research on Major Problems, pp. 273–297. Univ. Missouri Press, Columbia). Aggregates are classified as asocial or simple aggregates (reacting to stimuli other than conspecifics) and biosocial aggregates or schools (reacting to stimuli of conspecifics) (Bragg 1948. Wasman Collector 7:65–79; Wassersug 1973, *op. cit.*).

In this note we describe for the first time gregarious behavior in tadpoles of *Bufo spinulosus papillosus*. Its distribution covers Patagonian forests and steppes, and it typically breeds in ephemeral and semi-permanent environments during spring. We studied a population in a semi-permanent pond in northwestern Patagonia (41°10'S, 71°19'W; 906 m elev., Río Negro Province, Argentina). Observations began when clutches appeared in the austral spring. We recorded water depth, temperature (inside and outside the aggregate), and the characteristics of the substrate and vegetation where the aggregates were found. Aggregation sites were identified and marked. Aggregate density was measured using a ring of known surface area (380 cm^2), and aggregates classified as: low tadpole density ($\leq$ 20 individuals), medium (20–50), and high (> 50). Tadpole behavior within the aggregates was recorded and classified according to three categories: feeding on the substrate, swimming, and resting on the bottom. The composition of developmental stages was analyzed (Gosner 1960. Herpetologica 16:183–190).

Thirteen clutches were found during 5–6 October 2001. After hatching at Gosner Stage 18, individuals remained on the pond sediment under the gelatinous string remains. During the first week, tadpoles reached Stage 24, characterized by active swimming very near the hatching site, without feeding or aggregating. Aggregates were formed at two weeks, when the tadpoles were predominantly Stage 28, on sunny days, when the body of water was thermally stratified. The tadpoles from all 13 clutches formed 9 aggregates that remained together until metamorphosis (Stage 42). Of the 9 aggregates, 3 were high-density, 4 medium-density, and 2 low density. Aggregates were located in the shallowest, warmest zones with silt on the bed (except for two cases where there were pebbles and stones on the bed). Aggregates were found either lined up at the shore or forming irregular patches. Aquatic and paludal vegetation was almost absent from the aggregation sites except at one site where there was a dense stand of rushes. Mean temperature at the aggregation sites was 25°C ± 1.5 (24–28°C). The temperature within the aggregate was over 1°C higher than that of the surrounding water. The tadpoles had a daily migration cycle. During the morning, they were at the bottom of the pond under the vegetation (metaphyton and aquatic plants, e.g., *Myriophyllum*). When the temperature in the shallow zones rose, the tadpoles swam towards the shore and grazed actively on rocks or aquatic plants. Between 1200–1300 h there was maximum tadpole activity during feeding. At about 1400 h, the aggregates formed in the shallow zones, with the tadpoles resting on the substrate near the shore. Aggregates did not form on cloudy days, when the temperature was homogeneous throughout the pond.

Our results suggest that temperature is an important factor in the formation of *Bufo spinulosus papillosus* aggregates, which could therefore be classified as asocial aggregates. Moreover, since these tadpoles are very dark and uniformly colored, and inhabit shallow, sunny environments, their aggregates could fulfill a thermal regulation function, as suggested for other species by Brattstrom (1962. Herpetologica 18:30–46). Nevertheless, we cannot dismiss the possibility that other factors might act synergistically on aggregate formation in this species.

COCHRANELLA GRANULOSA (NCN). **FIGHTING BEHAVIOR.** In many species of anurans, vocalizations are sufficient to ward off an intruding male, but physical fighting might also be an important aspect in spacing of individuals at breeding sites (Duellman and Trueb 1986. The Biology of Amphibians, McGraw-Hill Co., New York. 670 pp.). Species of Centolenidae breeds in mountain streams of the Neotropics where male frogs exhibit intraspecific spacing and defend territories through vocalizations, and sometimes physical fighting (McDiarmid and Adler 1974. Herpetologica 30:75–78). Because of the lack of observations on centrolenid behavior, very few species have been observed in physical, intraspecific fighting. Fighting behavior has been reported in 5 of the >136 species (Guayasamin and Bonaccorso 2004. Herpetologica 60:485–494), and two of the three centrolenid genera. Males of *Hyalinobatrachium fleischmanni*, *H. valerioi* (McDiarmid and Adler 1974. Herpetologica 30:75–78), *Centrolenella prosoblepon* (Jacobson 1985. Herpetologica 41:396–404), *C. griffithsi* (Duellman and Savitzky 1976. Herpetologica 32:401–404), and *Cochranella buckleyi* (Bolȉvar-G. et al. 1999. Alytes 16:77–83) have been observed fighting during the breeding season. Aggressive behavior in Centrolenidae includes vocalizations directed towards the intruder, charging, kicking, shoving, grappling, and wrestling (Duellman and Savitzky 1976, *op. cit.*; Jacobson 1985, *op. cit.*), and such behaviors can be energetically costly and physically damaging Bolȉvar-G. et al., *op. cit.*). Herein we report on the fighting behavior of *Cochranella granulosa* and provide a brief description of aggressive vocalizations emitted during the fighting.

We observed two male *C. granulosa* engaged in a fight on 21 Sept 2001 at Río Tigrillo, Conte, Puntarenas Province, Costa Rica (N8°26'27.6", W83°01'30.0" elev. 52 m), near the Panamanian border. Cattle pastures, oil palm plantations, and scattered native trees and leafy herbaceous undergrowth (Heliconiaceae and Marantaceae) bordered the stream. The encounter was filmed using a Sony SONY CCD-TR940 video camera with night vision capabilities, and vocalizations recorded with a Marantz PM 222 shotgun microphone. The two individuals were first observed at

1944 h hanging 2.5 m above the stream, and our observations were concluded at ca. 2215 h. We did not observe the initiation of the bout and were unable to identify the intruder, the resident frog, or the true duration of the bout. When first observed, the frogs were hanging upside down belly-to-belly, one frog was hanging from the leaf by the right foot, while the other frog was hanging by both feet. We heard and/or saw at least 5 additional males calling from the same leafy bush. The typical advertisement call for this species has been described as a high pitched, three-note "creek-creek-creek" (Ibáñez et al. 1999. The Amphibians of Barro Colorado Nature Monument, Soberania National Park and Adjacent Areas, Panama, Editorial Mizarachi y Pujol). The first 24 minutes passed with both animals making soft "peep" calls at different intervals until the frog with both feet on the leaf started using its right foot to kick the second frog's foot off of the leaf. This behavior continued until both frogs, with arms wrapped around one another, fell ca. 1.0 m onto a lower leaf.

At this point the fight became more active and aggressive as both frogs jumped towards each other, collided, and wrestled. Throughout the fighting we observed pushing and kicking of the head and body, with some blows directed directly towards the eyes. Sporadically, after small wrestling bouts, the two frogs would separate for a couple of minutes and then jump towards each other again, repeating the colliding and wrestling. While the frogs were separated between bouts each frog would emitted a short, single-noted "creek" vocalization similar in pitch to the species typical "creek-creek-creek" advertisement call. As one frog produced the "creek" vocalization the second frog became aggressive and attacked the vocalizing frog. During the bout the frogs were continuously falling down to lower leaves until finally they were ca. 1.5 m above the stream. After descending to this point the fighting stopped temporarily as the frogs climbed back up the plant to higher perches. This did not happen simultaneously, but instead one male climbed first, and after several minutes the second male followed suit. Once at this perch, where the two frogs were originally observed, they began the physical fighting again.

During the second bout the frogs wrestled until they were hanging upside down, again apparently trying to knock the other frog off of the leaf. The two frogs fought in the same manner as described above until they were again ca. 1.5 m above the stream. At this point, 2 h and 24 min after the initial observation, the two frogs separated and ceased aggressive, physical combat. As they separated, one of the male frogs climbed through the vegetation near the original perch and began to emit the normal "creek-creek-creek" advertising vocalization. The other male frog, presumably the loser, hopped horizontally into the denser vegetation where we lost sight of him.

During our observations at this site we noticed three distinct calls from *C. granulosa*, including two that are previously undescribed. They were: 1) the advertisement call of "creek-creek-creek"; 2) a short, soft "mew" as the males were grappling belly-to-belly; and 3) a single-noted call—"creek"—similar in pitch to the normal advertisement call, which was heard during times of slight separation. The "mew" call has been described to function as an encounter call in other centrolenid species (McDiarmid and Adler 1974, *op. cit.*; Wells 1977. Anim. Behav. 25:666–693; Greer and Wells 1980. Herpetologica 36:318–326), and appeared to serve the same function in this observation. This is the sixth species of centrolenid known to exhibit fighting behavior, and the second observation in the genus *Cochranella*. Of the other centrolenid species that exhibit fighting, two have parental care in which males guard egg clutches, and three do not have parental care, including *C. granulosa*. In *Hyalinobatrachium*, males repeatedly guard multiple clutches on the same leaf (Jacobson 1985, *op. cit.*, Hayes 1985. Unpubl. PhD. Diss., Univ. Miami) and it could be surmised that the protection of offspring would facilitate fighting behavior. We suspect that in *C. granulosa* fighting behavior is used to establish and defend territory or a calling perch that attracts mates and leads to male–male spacing. It might be possible, as more behavioral observations are documented, to use fighting behavior as a phylogenetic character to organize species relationships in this diverse Neotropical frog family, and to understand how aggressive behaviors affect fitness and the social system of anurans.

CONRAUA GOLIATH (Goliath Frog). **SKITTERING LOCOMOTION**. Typically, anurans are specialized for saltatory locomotion. This is an excellent mechanism to avoid encounters with potential predators. In frogs, escape behavior usually consists of a single long leap to a secure place, such as from land into water, which is characteristic for ranids (Duellman and Trueb 1986. Biology of Amphibians, McGraw-Hill, Inc., New York 670 pp.). An alternate escape behavior is the unusual skittering locomotion; "bouncing" on the water surface without sinking (Gans 1976. Ann. Zool. 12:37–40), from a perching site on land as described for *Hoplobatrachus occipitalis* (Chabanaud 1949. Copeia 1949:288), *Acris crepitans* (Blair 1950. Copeia 1950:237; Hudson 1952. Copeia 1952:185), and *Hyla cinerea* (Janson 1953. Copeia 1953:62).

We observed skittering behavior in *Conraua goliath* along riverbanks of the Nkebe River, Littoral Province, Cameroon (04°50'N, 09°55'E) during March–April 2004. Generally, frogs were perched on rocks and gravel banks within the river or on solid rock at the edge of large rock pools. Sizes varied from recently metamorphosed froglets (3–4 cm SVL) to juveniles and large adults 20 to ≥ 30 cm SVL. When we approached *C. goliath* within a few meters, most showed a ranid-typical escape behavior of jumping into larger bodies of water with one powerful leap. However, some individuals exhibited a straight-line series of five to seven short leaps in even intervals which kept them on the water surface before finally diving into the water. Frogs always escaped into the water as opposed to land even when approached from the "water side." The frogs' bodies were supported on the water surface by repeatedly and simultaneously striking the surface with both feet, which are fully webbed and possess an exceptionally large surface area. The distance covered on the water surface was 2.5–3.5 m in adults and was comparatively smaller in juveniles and recently metamorphosed individuals. We observed this locomotion during most times of the day and at night (0930–

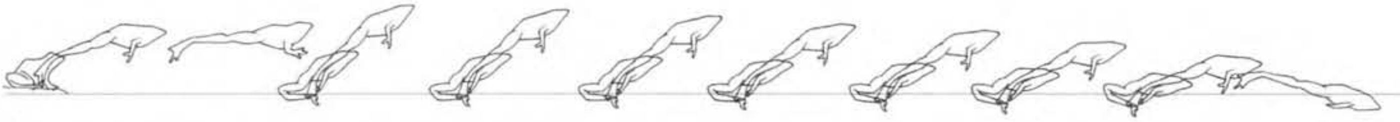

FIG. 1. Skittering behavior in a *Conraua goliath*.

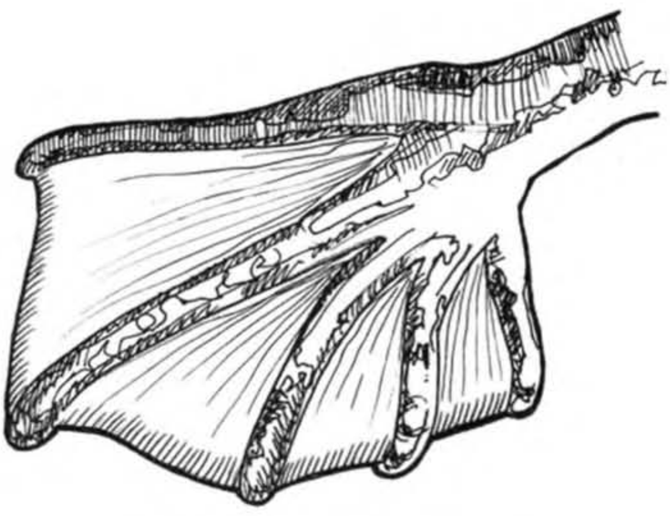

FIG. 2. Fully webbed right foot of a *Conraua goliath*.

2100 h). It seemed unrelated to particular microhabitat structures (i.e., shallow water).

Hudson (1952, *op. cit.*) suggests a selective advantage for skittering locomotion in *Acris crepitans* when predated by fishes. In Goliath Frogs there might be an advantage when dealing with aquatic predators such as fishes, giant ottershrews (*Potamogale velox*), otters (*Aonyx* and *Lutra* spp.), and crocodiles (*Crocodylus* and *Osteolaemus* spp.). These are likely to approach frogs, perched on land, from the water and possibly can follow them under water after their escape with a single leap. The frog's first escape phase on the water surface before submerging, as described here, might aid in confusing the predator and make predation less likely.

We thank the Cameroon Ministry of Scientific and Technical Research (MINREST) and the Ministry of Environment and Forestry (MINEF) for granting permits. The traditional authorities of the Bakaka tribe gave us access to the study area. We thank Wolfgang Böhme for discussions and literature. We are grateful to Tchiengue Barthelemew, Echalle Solomon, Djire Dansala, Joseph and Celestine for their help and support in the field.

CROSSODACTYLUS CARAMASCHII (NCN). **MORTALITY.** *Crossodactylus caramaschii* is a diurnal, stream-dwelling anuran found in the Serra de Paranapiacaba, state of São Paulo, southeastern Brazil (Bastos and Pombal 1995. Copeia 1995:436–439). The species calls from emergent rocks in forest streams, where their eggs are laid and the tadpoles develop. During Sept 2003 in the municipality of Apiaí (24°33'45"S, 48°48'45"W; 925 m elev.) in the Atlantic Forest of the state of São Paulo, Brazil, five dead or moribund *C. caramaschii* were collected. These frogs were found recently dead on the rocks of the stream (N = 2) or were heard calling and died shortly after collection (N = 3). This situation is similar to the pattern reported from localities where local extinctions have been associated with infection by the chytrid fungus *Batrachochytrium dendrobatidis*, which causes chytridiomycosis (Berger et al. 1998. Proc. Nat. Acad. Sci. USA, 95:9031–9036). Clinical signs of amphibian chytridiomycosis include abnormal posture, lethargy, and loss of righting reflex (Daszak et al. 1998. Emerg. Infect. Dis. 5[6]:735–748). The first record of *B. dendrobatidis* in Brazil was reported from Serra da Mantiqueira in *Hylodes magalhaesi* (Leptodactylidae), a diurnal, stream dwelling frog closely related to *Crossodactylus* (Carnaval et al. 2005. Froglog 70:3). Although the dead or moribund *C. caramaschii* collected were not tested for the presence of *B. dendrobatidis*, the pattern of death observed suggests infection by this fungus. Therefore, *B. dendrobatidis* might be more widespread in Brazil than reported.

Identification of these frogs was verified by Vanessa K. Verdade, and four were catalogued at the Museu de Zoologia da Universidade de São Paulo (MZUSP 133906–909).

Submitted by **RICARDO A. GUERRA-FUENTES**, Museu de Zoologia da Universidade de São Paulo, Av. Nazaré, 481, CEP 04263-000, Brazil (e-mail: ricardoa@ib.usp.br); and **MARIANNA DIXO,** Universidade de São Paulo, Instituto de Biociências, Departamento de Ecologia, CEP 05508-900, Brazil.

HYLA CALCARATA (Rana de Espolones) and ***HYLA FASCIATA*** (NCN). **DEFENSIVE BEHAVIOR**. Anurans are known to display a wide variety of defensive behaviors to avoid predation. During a study conducted at two field sites (Tambopata Research Centre, Department of Madre de Dios and the Amazon Conservatory for Tropical Studies, Department of Loreto) in Amazonian Peru in May and June 2004, we observed and collected specimens of *Hyla calcarata* and *H. fasciata*. When individuals of these species were stimulated either through tapping on the head or grasped with the hand, we observed an unusual defensive behavior that was similar in both species. This behavior consists of closing the eyes, bringing the forelimbs to the head, positioning the thumb either beneath the lower jaw or beneath the lower edge of the eye, and positioning the remaining fingers splayed straight, either be-

low the lower edge of the eye or at eye level. We have used the term "boo behavior" to describe this behavioral pattern. We observed boo behavior in 11 of 14 *Hyla fasciata* (79%; museum vouchers: MUSM 19326, 19331, 19414, 19445, 19447, 21634, 21635) and in one *H. calcarata* (MUSM 19328). A somewhat similar behavior has been reported for *Boophis albilabris* (Andreone 2002. Herpetol. Rev. 33:299–300), although in the figure provided this species keeps the fingers scrunched together, whereas in *H. calcarata* and *H. fasciata* the fingers are stretched out.

The adaptive value of this behavior might reside in sending an "anti-signal" to potential predators, as it is possible that their search-image may be thrown off by a dramatic change in the familiar frog outline, as suggested by Channing and Howell (2003. Herpetol. Rev. 34:52). Alternately, an "increase" in head size, or making potential ingestion difficult by assuming this posture could account for this behavior. It is possible that this boo behavior might be phylogenetically constrained in *H. calcarata* and *H. fasciata*, but other related species need to be tested, in addition to performing necessary cladistic analyses.

We wish to thank Antje Chiu, Karina Quinteros, and Claudia Torres for help and company in the field. Thanks to Glenn K. Morris for helpful discussion. Support for fieldwork was provided through NSF grant number IBN-0078150 to D. Cannatella. We also thank the Instituto Nacional de Recursos Naturales (INRENA) of Peru for collecting permits (08 C/C-2004-INRENA-IANP and 032-2004-INRENA-IFFS-DCB).

LEPTODACTYLUS LABYRINTHICUS (Labyrinthicus Frog). **PREY**. *Leptodactylus labyrinthicus* belongs to the *pentadactylus* group and is one of the largest Brazilian frogs. Although its diet has been reported to be composed mostly of insects (França et al. 2004. Stud. Neotrop. Fauna Environ. 39:243–248), this species also preys on frogs and small snakes (Cardoso and Sazima 1977. Ciência e Cultura 29:110–1132; Sazima and Martins 1990. Mem. Inst. Butantan 52:73–79). During a bat survey in the Santuário Ecológico da Serra da Concórdia, municipality of Valença (600 m elev.), Rio de Janeiro, southeastern Brazil, we observed an attempt by *L. labyrinthicus* to prey upon a bat. At 2115 h, on 5 April 2005 while one of us was removing a Screaming Bat (*Anoura caudifer*) (mean mass 11 g) from a mist net, another bat, probably of the same species became entangled in the net for a few moments and then flew out a few centimeters above the ground. Immediately, a male *L. labyrinthicus* (340 g) captured the bat and started to ingest it. The bat was not completly swallowed because the wings remained opened. The frog released the bat as soon as the researcher caught it. Although this observation was possible only because of the bat becoming entangled in the net, a large number of small bats were observed in the area and it is possible the frog could catch additional bats.

C. F. Rocha (Ecology Department, UERJ) confirmed the identification of the frog which was deposited in the Museu Nacional, Rio de Janeiro (MNRJ N39310).

Submitted by **CARLOS E. L. ESBÉRARD**, **TÁSSIA JORDÃO**, **LUCIANA M. COSTA** and **HELENA G. BERGALLO**, Department of Ecology, UERJ, Rua São Francisco Xavier 524, 20550-013, Rio de Janeiro, RJ, Brazil (e-mail: cesberard@terra.com.br).

LEPTODACTYLUS MYSTACINUS (Shovel-Nosed Frog). **PARENTAL CARE**. Species of *Leptodactylus* in the *fuscus* group are known to build foam nests in underground chambers (Lescure 1972. Ann. Mus. Hist. Nat. Nice. 1:91–100; Giaretta and Kokubum 2004. Herpetozoa 16:115–126). The observation reported herein was made in Uberlândia, Minas Gerais, Brazil. On 13 October 2004 (ca. 1900 h), we found a courting pair of *L. mystacinus* and followed them until they entered the nest chamber. We returned to the site the following night (1930 h) and found the chamber entrance sealed with soil and an individual (likely a male) of the species nearby (ca. 10 cm). We opened the entrance and found a foam nest within the chamber. We left the site for 1.5 h and upon our return the chamber entrance was sealed again and the frog

was even closer (ca. 5 cm) to it. We again opened the entrance (the attendant individual remained motionless meanwhile) and observed the frog's behavior. Within five minutes the frog started closing the entrance of the nest chamber by pushing soil into it with its snout. When the entrance was almost closed, the frog threw loose soil into it by fast kicking to the side. The frog worked ca. 20 min. to completely seal the entrance. The following night (2100 h) the individual was not found beside the nest. The following day (900 h) we found the chamber entrance opened (ca. 20 × 15 mm) and the egg mass missing. Remaining with the egg mass the night after spawning and working to seal the damaged entrance indicate parental care in *L. mystacinus*. There are brief reports on parental care in *L. fuscus* (Lescure, *op.cit.*; Solano 1987. Amph.-Rept. 8:111–128) and chamber sealing in *L. bufonius* (Reading and Jofré 2003. Amph.-Rept. 24:415–427). Although not effective in this report, the parental behavior of *L. mystacinus* might enhance the survivorship of egg/tadpoles in the nest chamber.

OSTEOPILUS SEPTENTRIONALIS (Cuban Tree Frog). **REPRODUCTION.** Males are often more abundant than females in breeding aggregations of anurans. This sex bias makes competition between males intense, and can promote diverse mating strategies (Anderson 1994. Sexual Selection. Princeton University Press, Princeton, New Jersey. 599 pp.), including amplexus displacement. Here, I document amplexus displacement in *O. septentrionalis*, a tree frog endemic to Cuba, but introduced in Hawaii, Georgia, and Florida (USA), Costa Rica, Puerto Rico, and other islands in the West Indies (Duellman 2001. The Hylid Frogs of Middle America. SSAR Contrib. Herpetol. 18:1–1180 pp.; Meshaka 2001. The Cuban Treefrog in Florida: Life History of a Successful Colonizing Species: University of Florida Press, Gainesville, Florida). Aspects of the natural history of *O. septentrionalis* and the potential detrimental impact of this species in invaded habitats have been studied (Meshaka 2001, *op. cit.*; Smith 2005. Biol. Cons. 123:433–441) but many details of its breeding behavior have not been published.

The following observations were made in a semi-permanent pond in Region San Antonio, Quebradillas, northwestern Puerto Rico (N18°25.113', W66°54.266'). At 0048 h on 14 Aug 2004, I observed a male *O. septentrionalis* (56 mm SVL) trying to remove an amplectant male (55.5mm SVL) from the dorsum of a female (82.5 mm SVL). The individuals were positioned in the top of a scrub (*Aeschynomene sensitive*, Leguminoseae) at a height of 1 m (Fig. 1). The intruder male attempted to pull the amplectant male off of the female, but the amplectant male moved its body and stopped the advance of the intruder male. There was not conspicuous movement of the amplectant male's hind limbs as recorded in other anurans (Davis and Halliday 1979. Anim. Behav. 27:1253–1267). Most of time the males were quiet, resting between movements and pushing attempts. The female did not move except when she jumped to the ground (0139 h) among dense vegetation (*A. sensitive* and *Ipomea tiliasea* Convolvuleaceae). Finally, when the amplectant male was pulled off the female it did not try to resume its amplexus position. This observation lasted for 1 h and 13 min, yet did not begin until after the males were engagement in conflict and the female was bleeding from the left side of her head. These individuals were not collected, but vouchers of the same population are deposited in the Museum of Zoology, University of Puerto Rico, Rio Piedras Campus (UPR 6276–77; 6279; 6283).

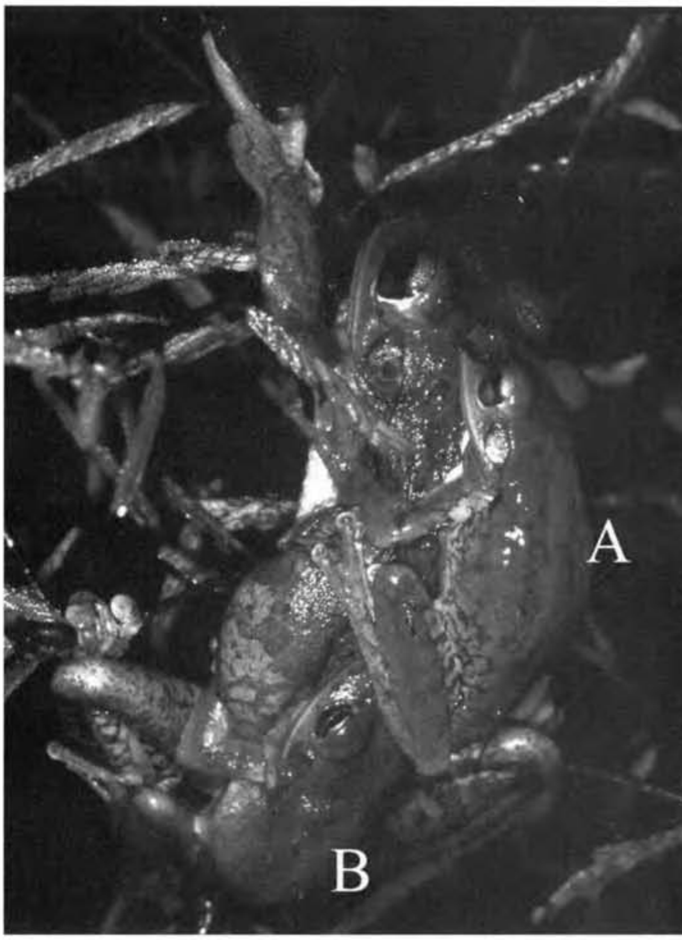

FIG. 1. Amplexus displacement in *Osteopilus septentrionalis*; A = amplectant male, B = intruder male.

Physical interactions between paired and unpaired male *O. septentrionalis* were often observed in breeding aggregations monitored during 2003 and 2004, but only the event described above was successful. Thus, in *O. septentrionalis* amplexus displacement apparently does not play a major role in the reproductive success of males.

I thank Marcos Caraballo and Frank Axelrod for plant identification, and Wilfredo Hernandez Aguiar and Ivan, Irvin, and Edsel Igartua Butler for help with fieldwork. These observations were made during MS thesis fieldwork of the author, which was supported by the University of Puerto Rico and IDEAWILD.

Submitted by **FERNANDO VARGAS-SALINAS**, Department of Biology, University of Puerto Rico-Río Piedras Campus, P.O. Box 23360, San Juan, Puerto Rico, 00931-3360; e-mail: vargassalinasf@yahoo.com.

PHRYNOPUS COPHITES (Cuzco Andes Frog). **REPRODCUTION**. *Phrynopus cophites* is a small leptodactylid frog of the Eleutherodactylinae clade endemic to the Cordillera de Paucartambo in the Peruvian Department of Cuzco (SE Peru). The species is only known from its type locality (Lynch 1975. Occas. Pap. Mus. Nat. Hist. Univ. Kansas 35:1–51); the southern slope of the Abra Acjanaco (13°10'9"S, 71°37'87"W, 3400 m elev).

On 7 Jan 1998 I found a brooding adult female (SVL 26.0 mm) *Phrynopus cophites*. The specimen was under moss in the puna (high Andean grassland), locality Acajanaco, Manu National Park (13°10'8"S, 71°38'05"W [datum: WGS84]; elev. 3410 m), Provincia Paucartambo, Departamento Cuzco, Peru. The nest contained 20 eggs (19 alive and 1 dead), each ca. 4 mm in diameter. I removed the nest and adjacent moss and kept them in a plastic box at ambient temperature. I measured the size at birth of juveniles as they were hatching: 6.3 mm (9 Jan), 6.9 and 6.3 mm (10 Jan), 6.1 mm (11 Jan), 6.2, 6.1, 6.3, and 6.4 mm (12 Jan), 6.6, 6.8, 6.2 and 6.7 mm (13 Jan), 6.8, 6.3, 6.5, 6.1 and 6.3 mm (15 Jan), 6.2 mm (16 Jan), 6.2 mm (19 Jan). Egg diameter a day before hatching varied from 4.8 to 5.3 mm (N = 8 eggs).

Frogs of the genus *Phrynopus* occur in páramo, puna, and cloud forests along the eastern slopes of the Andes from Colombia to Bolivia, where at least 34 species are presently known (Frost 2004. http://research.amnh.org/herpetology/amphibia). Recent descriptions of new species and a review of the genus (Lynch 1975, *op. cit.*) do not document any type of parental care for this genus, although terrestrial clutches and nest attendance have been reported in other eleutherodactylines (Duellman and Trueb 1994. Biology of Amphibians. Johns Hopkins Univ. Press, Baltimore). As far as I know, this is the first report of parental care, clutch size, and size at birth of juveniles for a species of *Phrynopus*.

PHYLLOMEDUSA DISTINCTA (Leaf Frog). **MULTIMALE SPAWNING**. Multimale spawning in anurans is rarely reported. To date, simultaneous polyandry has been directly observed in six rhacophorids (Coe 1967. Nature 214:112–113; Coe 1974. J. Zool. Soc. Lond. 172:13–34; Fukuyama 1991. An. Behav. 42:193–199; Feng and Narins 1991. Naturwissenschaften 78:362–365; Jennions et al. 1992. Anim. Behav. 44:1091–1100; Kasuya et al. 1996. Research. Pop. Ecol. 38[1]:1–10), one bufonid (Kaminsky 1997. Herpetol. Rev. 28:84), one myobatrachid (Roberts et al. 1999. Anim. Behav. 57:721–726), two leptodactylids (Prado and Haddad 2003. J. Herpetol. 37:354–362), and four hylids in the subfamily Phyllomedusinae (Pyburn 1970. Copeia 1970:209–219; Roberts 1994. J. Herpetol. 28:193–199; Wogel et al. 2005. J. Nat. Hist. 39:2035–2045). Here we describe the occurrence of simultaneous polyandry in another phyllomedusine, *Phyllomedusa distincta*.

Observations were made in two permanent ponds located in remnants of Atlantic rainforest, Brazil. From September 1991 to February 1992, the study was conducted in the Parque Estadual Carlos Botelho, Municipality of Sete Barras, State of São Paulo (24°12'S; 47°55'W), and from August 2001 to October 2003, observations were made in the Municipality of Guaramirim, State of Santa Catarina (26°27'S; 49°00'W).

The observed pairs deposited egg clutches wrapped in leaves above water. During the observations in the Parque Estadual Carlos Botelho, three male *P. distincta* were observed trying to fertilize the eggs of one female. In other occasions, we observed single

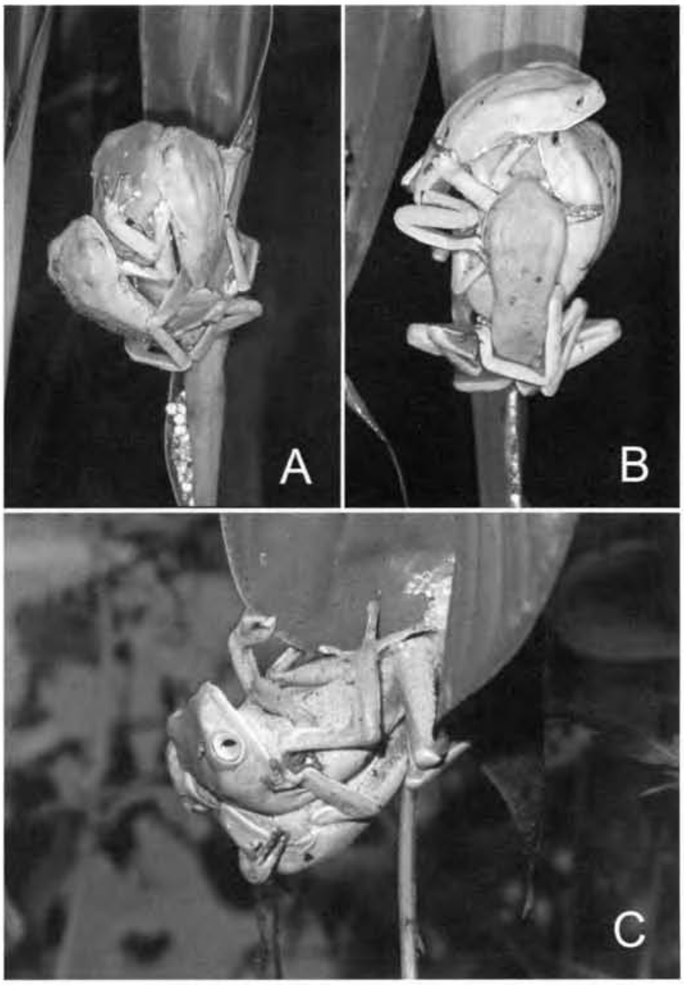

Fig. 1. Multi-male spawning in *Phyllomedusa distincta*. A) One female with two males; B) one female with three males; and C) a female dislodged from the leaf by two males.

males trying to join a pair already in amplexus, but they were not successful. Multi-male spawning in *P. distincta* was observed four times during the study conducted in the Municipality of Guaramirim. In three occasions (August 2001, September 2002, and October 2003) we observed two males spawning with one female (Fig. 1A). In September 2002, we saw three males with a female (Fig. 1B). In these four cases, after entering in amplexus, the female carried the male to an appropriate site to spawn, generally 3–4 m from the calling site. Additional males usually join the pair just before spawning begins; we have never seen a female transporting more than a single male on her back. The opportunistic males try to position their cloacae close to the eggs that are being deposited. After spawning was complete, the males slowly went away and the female remained to conclude the leaf sealing by depositing empty egg capsules to glue the leaf margins and to protect the eggs against desiccation. These clutches were monitored and egg development and hatching succeeded in three of the cases, including that with three males. However, in one occasion, when a female was spawning with two males, their weight disturbed the female by pulling her down and prevented her from sealing the leaf (Fig. 1C). The result was that almost the entire clutch desiccated. Furthermore, simultaneous polyandry was observed several times at Guaramirim, including one observation with four males with one female. The low number of cases of multimale spawning reported for anurans suggests that in general, the costs involved are higher than the advantages (Lodé and Lesbarrères. Naturwissenschaften 91:44–47). However, the advantages for the females could be to increase the chance of fertilization or the genetic diversity of offspring. For the opportunistic males, polyandry could increase the chances of fertilizing at least some eggs. Thus, mating with more than one male may be more common for anurans than reported (Roberts et al. 1999. Anim Behav. 57:721–726) and the recent increase in the number of cases reported seems to confirm this (e.g., Prado and Haddad, *op. cit.*; Wogel et al., *op. cit.*).

We thank C. F. B. Haddad for the valuable suggestions on the manuscript, FAPESP for support to the Herpetology Lab, Departamento de Zoologia, Unesp, Rio Claro, São Paulo, Brazil (Biota proc. no. 01/13341-3); Neotropical Grassland Conservancy and Idea Wild for lab equipment donation, CNPq, CAPES, FAPESP, and Fundação O Boticário de Proteção à Natureza for grants and scholarships.

Submitted by **CYNTHIA P. A. PRADO** (e-mail: cpap@rc.unesp.br), **LUÍS FELIPE TOLEDO** (e-mail: toledo@rc.unesp.br), Departamento de Zoologia, Instituto de Biociências, Universidade Estadual Paulista, Caixa Postal 199, 13506-970, Rio Claro, São Paulo, Brazil; **GERMANO WOEHL JR.**, Instituto Rã-Bugio para Conservação da Biodiversidade, Estrada Rio da Prata, 523, Caixa d´Água, Guaramirim, Santa Catarina, 89270-000, Brazil; and **LUCIANO MENDES CASTANHO,** Departamento de Morfologia e Patologia, Centro de Ciências Médicas e Biológicas, Pontifícia Universidade Católica de São Paulo, Praça Dr. José Ermírio de Moraes, 290, 18030-230, Sorocaba, São Paulo, Brazil.

PLEURODEMA NEBULOSA (NCN). **BODY TEMPERATURE.** *Pleurodema nebulosa* occurs in the arid areas of western Argentina, the Catamarca Mountains to the Rio Negro province. This distribution coincides with the Monte Phytogeographic Province (Cei 1980. Amphibians of Argentina. Ital. J. Zool., N. S. Monogr. 2, 609 pp.). The objective of the present work is to investigate selected parameters of the thermal ecology of this species: What is the average cloacal temperature (Tc) of the population? Is there an association between Tc and substrate temperature (Ts) and air temperature (Ta)? Is there a relationship between Tc and SVL?

The study area is located 40 km N of San Juan City on National Route N 40. Elevation reaches 800 m; the region is arid with an annual mean temperature of 16ºC. Rainfall occurs mostly during the summer with an annual average of 84 mm.

Thirty-one individual *P. nebulosa* were collected on 21 April 2005; cloacal temperature (Tc), substrate temperature (Ts), and air temperature (Ta) were measured to the nearest 0.1°C. Information was collected on substrate type and whether the individual was in the sun or shade.

Mean Tc was 22.8ºC (SD = 2.5, N = 31, range = 19.8–28.4°C). Tc was positively correlated with Ts ($r^2 = 0.75$ $p < 0.0001$, N = 31), and Ta ($r^2 = 0.75$, $p < 0.0001$, N = 31). There was no observed association between Tc and SVL ($p < 0.31$).

The results demonstrate that *P. nebulosa* is a thermal conformist, a mechanism where individuals do not need to invest time and energy actively selecting microhabitats for thermorregulation (Labra and Vidal 2003. *In* F. Bozinovic (ed.), Fisiologia Ecologica y Evolutiva, pp. 207–224. Ediciones Universidad Catolica de Chile. Santiago, Chile).

RANA AURORA DRAYTONII (California Red-legged Frog). **DEFENSIVE BEHAVIOR**. On 3 April 2004, I observed a subadult (68 mm SVL) *Rana aurora draytonii* exhibit a "hands-up" defensive behavior after I hand-caught the frog. The capture was part of a relocation program of *R. aurora draytonii* under a 404 permit housing development site under construction in the City of Dublin, Alameda Co., California, USA (U.S. Army Corps of Engineers, Permit No. 25144S). The same frog exhibited the behavior a second time approximately two hours after being captured and retained in a plastic bag, holding the position so that I could photograph it. This behavior is similar to that expressed in the Gopher Frog, *R. capito* (Means 2004. Herpetol. Rev. 35:163–164), with the hands raised up to the side of the head and turned outward exposing the palm in an apparent attempt to shield the eyes. The nictitating membranes covered the eyes but the eyelids were not shut. As with *R. capito*, the *R. aurora draytonii* exuded a musty secretion.

Of ca. 800 adult, subadult, and juvenile frogs caught and handled during the three-year relocation effort, only a few (< 10) individuals, all subadults, exhibited this behavior. In contrast, all of the adult frogs (> 84 mm SVL) would either struggle or go limp when handled, and the juvenile frogs (< 65 mm SVL) would tuck the

hindlimbs under the body and hold the forelimbs out as in preparation to jump away. Some of the adult frogs also produced a high-pitched, repetitive cry when handled.

Observing this behavior in *R. aurora draytonii* suggests that, although rarely exhibited, it might be more common among other species of ranid frogs than reported.

RANA BOYLII (Foothill Yellow-legged Frog). **PREDATION**. Select predators of *Rana boylii* are known, although predation by the California Giant Salamander, *Dicamptodon ensatus*, has not been reported. During a study along Big Carson Creek in Marin County, California, USA, I observed predation on *R. boylii* tadpoles by *D. ensatus* larvae.

On 21 March 2005 a *R. boylii* egg mass (Gosner Stage 9) was found attached on the side of a cobble located in a small shaded pool. On 1 April, the egg mass had fully hatched and 15 tadpoles were counted in the pool. Next to the hatched egg mass, a California Giant Salamander larva was preying directly on one of the tadpoles. Twenty minutes later, the *D. ensatus* larva was still immobile next to the egg mass. On 10 April, I observed three *D. ensatus* larvae at the pool; one of them located at the same place where the egg mass was previously attached. At that time, no tadpoles were found on that pool. I have never observed other large predators (fish, Rough-skinned Newts [*Taricha granulosa*], crayfish) at that breeding site excluding Coast Gartersnakes (*Thamnophis elegans terrestris*). Gartersnakes were observed for the first time on 17 April.

RANA CHIRICAHUENSIS (Chiricahua Leopard Frog) and ***RANA CATESBEIANA*** (American Bullfrog). **REPRODUCTIVE BEHAVIOR**. Reproductive interactions between amphibian species (Christman et al. 2000. Herpetol. Rev. 31:99–100; Kwet 2002. Herpetol. Rev. 33:47–48; Lind and Bettasso 2003. Herpetol. Rev. 34:234–235), families (Smith 2004. Herpetol. Rev. 35:374–375; Jennings et al. 2005. Herpetol. Rev. 36:53), and even orders (Höbel 2005. Herpetol. Rev. 36:55–56) has been well documented in the literature. Herein, we report the first documented observance of reproductive interference by the invasive, exotic *R. catesbeiana* with *R. chiricahuensis*, a species federally listed as threatened under the Endangered Species Act.

On 27 Sept 2003 at 1230 h, a male *R. chiricahuensis* was observed in amplexus with a female *R. catesbeiana* underwater ca. 0.46 m deep in a bedrock pool in Sycamore Creek [UTM Easting 12481804 / Northing 3476893 (NAD 27)], an intermittent stream in Santa Cruz County, Arizona. At the time of our observation, weather conditions were hot (32°C) and humid (ca. 50% RH) with high overcast. The specimens physically separated when we attempted to move them from partial obstruction for the purpose of photo documentation. Sycamore Creek is one of the few remaining strongholds of *R. chiricahuensis* in the United States and periodically is invaded by *R. catesbeiana*. Despite these invasions, *R. chiricahuensis* has maintained a population in Sycamore Creek.

The introduction and spread of *R. catesbeiana* from anthropogenic and natural means into the state of Arizona and throughout the western United States has had serious implications for native herpetofauna because of the risks of predation, competition, and the spread of disease. Reproductive interference is another concern of *R. catesbeiana* invasion. The effects of reproductive interference can be more significant than a temporary interference with a species' reproductive effort. A male *Spea hammondii* was once observed in amplexus with a female *Pseudacris regilla*; the latter died soon thereafter due to an apparent rupture of the abdominal wall (Wright and Wright 1949. Handbook of Frogs and Toads. Comstock Publishing Associates. Ithaca, New York. 640 pp.).

Ranid and hylid frogs as well as thamnophiine snakes have been documented as particularly vulnerable to the effects of *R. catesbeiana* invasion (Rosen and Schwalbe 2002. *In* Tellman [ed.], Invasive Exotic Species in the Sonoran Region, pp. 220–240. Univ. of Arizona Press and Arizona-Sonora Desert Museum. Tucson, Arizona). Reproductive interference is another possible adverse effect of *R. catesbeiana* invasion of *R. chiricahuensis* occupied habitat, a threat that has gone unrecognized to date.

We thank James C. Rorabaugh for his review of this manuscript.

SHARROCKS**, 20437 N. 17th Way, Phoenix, Arizona, 85024, USA (e-mail: freeformdesigns@cox.net).

RANA LUTEIVENTRIS (Columbia Spotted Frog). **REPRODUCTION**. Many amphibians that oviposit in temporary wetlands or wetlands where water levels fluctuate risk having their eggs stranded terrestrially. Terrestrial stranding of egg masses has been described most frequently for the Wood Frog (*Rana sylvatica*; Forester and Lykens 1988. Can. J. Zool. 66:1733–1735; Wright and Wright 1995. Handbook of Frogs and Toads of the United States and Canada, Comstock Publishing Associates, Ithaca, New York, 640 pp.). Many other amphibians have similar breeding habits (e.g., early spring, explosive, oviposit in shallow water), including *R. luteiventris* and its sister species *R. pretiosa* (Licht 1974. Can. J. Zool. 52:613–627), but survival of their eggs and other ranid frogs after stranding has been described less frequently. Herein, I report survival of *R. luteiventris* embryos for ≥ 21 days after becoming stranded.

On 6 April 2005 seven *R. luteiventris* egg masses that were laid communally between 1–5 April were found in ca. 5 cm of water in a wetland near Lost Horse Creek in the Bitterroot Mountains, Montana, USA (46°05'91"N, 114°15'82"W; 1324 m elev.), where breeding activity is monitored annually. A visit on 31 March indicated that breeding had not yet begun. Breeding by *R. luteiventris* in this wetland typically begins shortly after snow melts and the north half of the water's surface is ice free, usually during the first week in April. Most egg masses are deposited in shallow water

along the north shore. The egg masses were fully enlarged when I found them but no elongation of the embryos was evident (Gosner Stage < 14; Gosner 1960. Herpetologica 16:183–190). By the next visit on 8 April, the water level had dropped and the egg masses were perched atop a wet clump of dormant vegetation surrounded by mud. Four new masses had been laid on 6–7 April in a slight depression nearby and were in < 5 cm of water. Three of these four masses were laid communally, and the fourth mass was ca. 30 cm away. The group of seven masses was still stranded on 11 April and the four more recent masses were stranded by then as well. All of the masses were still stranded on 18 April but most embryos still looked viable and some were moving inside the egg jelly (ca. Gosner Stage 18). On 21 April I estimated > 90% of embryos in the stranded masses were still viable and development seemed to be proceeding at about the same rate as in non-stranded masses of similar age. Most tadpoles had congregated at the edges and low spots of the egg jelly and some that tried to emerge from the jelly were dehydrated and dead. Most tadpoles in a sample of ca. 20 (Gosner Stages 21–23) taken from the edge of an egg mass started swimming immediately after being placed in a bottle of water, and all were swimming by the next morning. Also on 21 April, tadpoles from egg masses of the same estimated age (laid between 1–5 April) that did not get stranded were free-swimming (Gosner Stages 21–25). On 25 April, all tadpoles in the stranded non-communal mass and most tadpoles in the communal egg masses were dead. However, some tadpoles (est. < 10%) in the two groups of communal masses remained alive in the areas with the deepest jelly and swam when placed in a bottle of water. By then, however, the egg jelly had developed a thick skin on its surface and it is uncertain whether tadpoles could have escaped even if the egg mass was inundated. All tadpoles in the two groups of communal masses were dead on 5 May.

Data from the Twelvemile Creek snow telemetry station (SNOTEL; 1647 m elev.; http://www.wcc.nrcs.usda.gov/snotel) ca. 14 km upstream of the Lost Horse Creek marsh indicate April 2005 was slightly warmer and wetter than the 1989–2004 mean. The average daily temperature was 3°C (range of daily averages: -1 to 8°C) and 7.9 cm of precipitation accumulated as snow and rain on 14 days between 1–25 April, often in increments of < 0.3 cm. The precipitation likely extended the viability of the stranded egg masses (Forester and Lykens, *op. cit.*), but I never found them inundated after they became stranded and the wetland continued to shrink throughout April. Maximum snow water equivalent (SWE; 18.5 cm) in 2005 was only 39% of normal and melted ca. 1 mo. earlier than the 1968–2004 average (48.0 cm), which resulted in a water deficit in the wetland and numerous stranded egg masses despite the periodic precipitation after breeding.

The ability of eggs to survive short-term terrestrial stranding is especially important to species that breed in wetlands where fluctuations in water levels are common. At this same wetland in 2000, I observed *R. luteiventris* tadpoles hatch from an egg mass that had been stranded for ca. 5 days before being re-inundated. Spring 2005 was the second time since 1999 that there has been complete loss of breeding effort at the Lost Horse Creek marsh. Years with complete loss of breeding effort coincided with the lowest (18.5 cm in 2005) and third-lowest (25.65 cm in 2001) maximum SWE at the Twelvemile Creek SNOTEL station since 1968. Licht (*op. cit.*) hypothesized mortality from stranding of egg masses was one of the strongest factors limiting *R. pretiosa* populations. The ability to survive short term terrestrial stranding may become even more important if climate change results in less predictable wetland hydroperiods (Brooks 2004. Wetlands 24:104–114).

I thank C. Pearl and S. Corn for comments on the manuscript.

RANA PRETIOSA (Oregon Spotted Frog). **PREDATION**. Greater Sandhill Cranes (*Grus canadensis tabida*) have a seasonally varied diet dominated by grains, tuberous vegetation, and macroinvertebrates (e.g., Davis and Vohs 1992. Trans. Nebraska Acad. Sci. 20:81–86; Mullins and Bizeau 1978. Auk 95:175–178; Reinecke and Krapu 1986. J. Wildl. Manage. 50:71–79). *Grus c. tabida* are reported to take frogs (Barrows 1912. Michigan Bird Life. East Lansing, Michigan Agric. College. 822 pp.; Littlefield *in* Mullins and Bizeau, *op. cit.*; Stern et al. 2002. *In* Marshall, Hunter, and Contreras [eds.], Birds of Oregon: A General Reference, pp. 198–200. Oregon State University Press, Corvallis), but the species taken have not been identified. Herein we report direct observations of *G. c. tabida* predation on *Rana pretiosa* from south-central Washington State.

Our observations were made on 10 March 2005 at Conboy Lake National Wildlife Refuge (CLNWR), Klickitat County (45°55–59'N, 121°15–23'S [datum: WGS84]; elev. 554 m). CLNWR includes part of a ca. 2500-ha seasonal marsh of palustrine emergent wetland habitats (*fide* Cowardin et al. 1979. Classification of Wetlands and Deepwater Habitats of the United States. US Fish and Wildlife Service, Office of Biological Services, FWS/OBS-79/31, Washington, D.C.). The system harbors the largest nesting population (19–20 pairs) of *G. c. tabida* in Washington State (JDE, unpubl. data) and perhaps the largest extant population of *R. pretiosa* across its geographic range (Hayes 1997. Status of the Oregon spotted frog (*Rana pretiosa*) in the Deschutes Basin and selected other systems in Oregon and northeastern California with a rangewide synopsis of the species' status. Report to The Nature Conservancy and US Fish & Wildlife Service, Portland, Oregon. 57 pp.).

At 1045 h, using 12 × 50 binoculars, MPH observed a group of 5 foraging adult *G. c. tabida*. At 1052 h, a large male *G. c. tabida* broke off from the group and began walking directly toward MPH, foraging as he went. Simultaneously, MPH heard the soft calls of several male *R. pretiosa* (see Licht 1969. Can. J. Zool. 47:1287–1299) coming from a shallow pool between himself and the approaching *G. c. tabida* (ca. 8 m in front of MPH). Examination of this ca. 20-cm deep pool through binoculars revealed a calling group of at least 7 *R. pretiosa*. Frogs were mostly calling underwater, but individuals would irregularly surface over several-minute intervals, only to re-submerge within seconds. Besides their eyes being visible, surfacing males produced ripples across the water surface that were evident from a distance. At 1107 h, the male *G. c. tabida* reached a location within 3 m of the *R. pretiosa* group, when one of the frogs surfaced and the *G. c. tabida* immediately noticed it. In the typical low foraging posture, the *G. c. tabida* closed the distance between it and the *R. pretiosa* in four steps and struck the frog with a sharp peck just as the frog dove.

The *G. c. tabida* then gave 5–6 additional pecks close to where the *R. pretiosa* dove, and within 30 sec, came up with what was presumably the same frog, positioned sideways with its mottled-orange belly turned upwards in the crane's bill. Less than 10 min later, this same *G. c. tabida* captured a second *R. pretiosa* from the same group. In both cases, the *R. pretiosa* prey appeared to be adult males, ca. 70 mm SVL. After the *G. c. tabida* had moved on, MPH captured and released 4 male *R. pretiosa* at the location of the observations that were 67–74 mm SVL.

Most of the 40-odd sites across *R. pretiosa* geographic range where the species is extant are also used by *G. c. tabida* (Hayes, *op. cit.*; JDE, MPH, unpubl. data). Co-occurrence can be attributed to similarity in species habitat requirements, but our observation suggests that a trophic relationship may need further consideration.

RANA PRETIOSA (Oregon Spotted Frog). **MAXIMUM SIZE.** As a candidate species for federal listing (USFWS 2005. Federal Register 70:24869–24934), *Rana pretiosa* has been the focus of much recent study (e.g., Marco et al. 1999. Environ. Toxicol. Chem. 18:2836–2839; Watson et al. 2003. J. Herpetol. 37:292–300; McAllister et al. 2004. Northwest. Nat. 85:20–25). Despite these efforts, few data exist regarding variation in *R. pretiosa* body size. Licht (1974. Can. J. Zool. 52:613–627; 1975. Can. J. Zool. 53:1254–1257) reported that female and male frogs in British Columbia mature at 62 mm snout–vent length (SVL) and 45 mm SVL, respectively; and recorded maximum sizes of 80 mm SVL (females) and 64 mm SVL (males). Based on collective data from several populations in Washington State, McAllister and Leonard (1997. Washington State Status Report for the Oregon Spotted Frog. [July] Washington Department of Fish and Wildlife, Wildlife Management Program, Olympia, Washington. 38 pp.) reported that adult males ranged from 46 to 66 mm SVL and adult females ranged from 51 to 89 mm SVL. McAllister and Leonard (*op. cit.*) further added that female *R. pretiosa* exceeding 90 mm SVL are rare, but exist in museum collections. This statement correctly implied that no *R. pretiosa* >100 mm had ever been recorded (K. McAllister, pers. comm.). Although Leonard et al. (1993. Amphibians and Reptiles of Washington and Oregon. Seattle Audubon Society, Seattle, Washington. 168 pp.) reported that Spotted Frogs reach 100 mm SVL, this statement was made before *R. luteiventris* was partitioned from *R. pretiosa* (see Green et al. 1997. Copeia 1997:1–7), making it unclear for which species this maximum was intended. Hence, we add to the data on variation in body size of adult *R. pretiosa* with reports of frogs >100 mm SVL from central Washington State, USA.

Our observations were made at Conboy Lake National Wildlife Refuge (CLNWR), Klickitat County (45°55–59'N, 121°15–23'S, WGS84; elev. 554 m). CLNWR includes part of a ca. 2500-ha seasonal marsh of palustrine emergent wetland habitats (*fide* Cowardin et al. 1979. Classification of wetlands and deepwater habitats of the United States. USFWS, Office of Biological Services, FWS/OBS-79/31, Washington, D.C.). CLNWR represents the only locality across *R. pretiosa*'s geographic range where it has co-existed with *R. catesbeiana* for >50 years (MPH, unpubl. data).

Between 2100 h and 0100 h on the nights of 19–20 and 20–21 August 2005, CJR and MPH systematically collected (i.e., specifically ignoring size) a series of post-metamorphic *R. pretiosa* from the seasonally shrunken remnant of Conboy Lake. We measured SVL (to the nearest 0.5 mm) and mass (to the nearest g) of each frog; the two largest frogs were photographed; and all individuals were subsequently released at their capture sites. Among the 30 *R. pretiosa* captured were 3 adult females >100 mm SVL; the size (and mass) of each female was: 103 mm (82 g), 104 mm (92 g), and 105 mm (97 g). On 11 July 2005, CJR captured an adult female *R. pretiosa* at CLNWR that measured 107.5 mm SVL (100.5 g), but no photograph was taken. Lastly, over the past 8 years, we have captured 12 different female *R. pretiosa* at CLNWR that were in the range of 101–103 mm SVL.

These frogs are all larger than the maximum size of "exceeds 90 mm SVL" reported for *R. pretiosa* (McAllister and Leonard, *op. cit.*), and of the 100 mm SVL reported for spotted frogs in general (Leonard et al., *op. cit.*). Notably, the high proportion (≥ 30%) of large (≥80 mm SVL) adult frogs recorded at CLNWR relative to 15 other *R. pretiosa* populations for which we have data is a pattern we have consistently observed since we began surveys there in 1996 (unpubl. data), and may reflect the unique local conditions influencing *R. pretiosa* size distribution. In particular, relatively long-term (>50 years) co-existence with *Rana catesbeiana* should be considered as a potential driver for this variation.

A photographic voucher for a large female *R. pretiosa* (105 mm, 97 g; Conboy Lake National Wildlife Refuge, Klickitat County, Washington State. UWBM 2301) was deposited (in electronic and hard copy) in the herpetological collection at the University of Washington Burke Museum. The Washington Department of Fish and Wildlife (Habitat Program, Science Division) and the USFWS (Ridgefield NWR Complex) supported this work.

HAYES**, Washington Department of Fish and Wildlife, Habitat Program, 600 Capitol Way North, Olympia, Washington 98501, USA (e-mail: hayesmph@dfw.wa.gov); and **JOSEPH D. ENGLER**, Ridgefield National Wildlife Refuge Complex, 301 3rd Street, Ridgefield, Washington 98642, USA (e-mail: joe_engler@fws.gov).

RANA SYLVATICA (Wood Frog) and ***AMBYSTOMA MACULATUM*** (Spotted Salamander). **BEHAVIOR.** Reports of multiple male anurans simultaneously attempting to mate with a single female of the same species are common, as are reports of male anurans attempting to mate with other anuran species (Vogt 1981. Natural History of Amphibians and Reptiles of Wisconsin.

Milwaukee Public Museum, Wisconsin. 205 pp.; Harding. 1997. Amphibians and Reptiles of the Great Lakes Region. Univ. Michigan Press, Michigan. 378 pp.). However, reports of multiple male anurans simultaneously amplexing with same-sex individuals from a different amphibian class are rare. Although Hobel (2005. Herpetol. Rev. 36:55–56) reported examples of salamander + frog breeding activity, these involved single anurans amplecting with single caudates (*Rana palustris* and *Ambystoma maculatum*). Furthermore, determining the sex of the caudates in these examples was not possible. Herein we report an instance of multiple male anurans simultaneously amplexing with a single male caudate.

On 9 April 2005 (ca. 1100 h) a survey of a woodland wetland near Stevens Point, Portage Co., Wisconsin, USA was being conducted for *Ambystoma maculatum* (which were reported to be breeding there a week prior). This survey yielded high numbers of *R. sylvatica* (calling males and amplectant pairs) and *Pseudacris crucifer* (only calling males), but few *A. maculatum*. After ca. 1 h of surveying, four male *R. sylvatica* were witnessed simultaneously amplexing with an object at the surface of the water among dormant cattails. Further investigation revealed that all were grasping a single *A. maculatum*, determined to be a male by its swollen cloacal lips. This male *A. maculatum* (8.7 cm SVL, 17 g) was lethargic, but alive, and later was released in a moist upland area. All male *R. sylvatica* escaped before further examination could be conducted. No other similar activity was witnessed during the remainder of the survey.

RANA TEMPORARIA (Common Frog). **MIGRATION**. Mass migration of *Rana temporaria* was recorded in the Eastern Carpathians, Ciuc Basin (46°21'N, 25°46'E), 700 m elev., between 25–28 March 2005. Occasional observations were made before and after this period. We made observations on a 1200-m section of a permanent mountain stream (0.2 m^3/s runoff, 3 m/100 m slope gradient) and on ponds used for reproduction close to the stream, surrounded by a cultural landscape (few houses, mostly hayfields and arable land). The stream flows into an old branch of the Olt River. We made fixed-point counts of drifting frogs at midday (1300–1400 h) and in the evening (2000–2100 h) for 10 minute intervals. We also observed the movement and behavior of frogs along the stream until the inflow, and recorded the presence-absence of frogs in potential breeding ponds known from previous studies (Demeter 2004. A Csíki Székely Múzeum Évkönyve 1:323–333 [in Hungarian]). We recorded up to 1.5 drifting frogs/minute at midday and 2.3–6.5 drifting frogs/minute in the evening. The main migration was observed in the evenings, significant movement of frogs during the day was recorded only on 25 March. The frogs were apparently in a torpid state, flowing passively with the drift. Along the pool sections they actively swam downstream. The migration peaked on 25 March, when in the evening we counted 65 drifting frogs in 10 minutes. The migration probably started a few days earlier, as no migrating frogs were observed on or before 20 March. On 26 March during the evening we counted 23 frogs in 10 minutes, on 27 March 47 frogs in 10 minutes, and on 28 March 24 frogs in 10 minutes. The changes in the number of drifting frogs were parallel with the changes of the stream water temperature measured at midday (5.1°C on 25 March, 2.1°C on 26 March, 5.6°C on 27 March, 4°C on 28 March). Calling choruses of males and frogs departing from the stream were observed between 25–27 March on the lower sections of the stream (1000–1200 m downstream from the location of the fixed-point counts). After 27 March no frogs were observed in the stream. On 28 March we counted 47 egg clumps in a large shallow pond close to the lower section of the stream and 2 egg clumps in another small pond situated 300 m upstream. The weather cooled down in the following days. On 31 March the number of egg clumps in the large lower pond was 350, and in the upstreams pond was 30. No egg clumps or common frog activity was observed in the rest of the ponds situated close to the stream.

The first documented observation of the mass migration of *Rana temporaria* in the Carpathians was made during April 1986 in the Retezat Mountains, at 1300 m elev. (Cogalniceanu 1991. Herpetol. Rev. 22:54). The author observed a synchronous movement of frogs from a terrestrial hibernaculum towards a nearby stream at noon that lasted ca. 30–40 min. The migration coincided with an increase in daytime air temperature to 16°C, while nighttime temperatures were still below 0°C. Our observations provide further evidence that *R. temporaria* uses mountain streams for the spring migration of up to several kilometers. Further studies are needed to document this type of migration rarely described in the literature for this species, and to investigate the geographical range and ecological significance of this behavior.

SCAPHIOPUS HOLBROOKII HOLBROOKII (Eastern Spadefoot). **ALBINISM**. Herein we report an observation of albinism in *Scaphiopus holbrookii holbrookii*. On 31 March 2003, we observed 65 albino larvae (Gosner Stage 36, Gosner 1960. Herpetologica 16:183–190) in a small diameter (35 m) ephemeral wetland in Gainesville, Alachua County, Florida, USA. The exact locality is withheld to ensure protection of this population. These albino individuals comprised ca. 1% of the entire *S. h. holbrookii* larval population.

The dorsal skin of each tadpole was light orange with a light yellow lyre-shaped marking bordered by a series of darker orange spots. The sides were light orange, and the venter was transparent with scattered yellowish-white flecks. The eyes were entirely orange.

Thirty tadpoles were collected with dipnets and returned to the lab for further study of their behavior, growth, and survivorship. All of these tadpoles successfully completed metamorphosis. One month after metamorphosis, these individuals exhibited coloration similar to the tadpole stage. The metamorphs had entirely orange eyes, a light orange dorsum and sides, and a translucent yellowish-white flecked venter. In addition, the individuals had numerous red tubercles on the dorsum. Some of these tubercles

reinforced the border of the light yellow lyre-shaped marking that was evident in the tadpoles. Because of their complete absence of melanin and presence of yellow, orange, and red pigmentation, these individuals fit the description of partial albino with xanthophores and erythrophores (Dyrkacz 1981. SSAR Herpetological Circ. No. 11). Color photos were deposited in the Florida Museum of Natural History (UF 140596).

To our knowledge, this is the second documentation of albinism in *S. h. holbrookii*. Albino tadpoles were previously observed in New Kent County, Virginia (Hensley 1959. Publ. Mus. Michigan State Univ. Biol. Ser. 1:135–159).

SCINAX FUSCOVARIUS (Snouted Treefrog), ***SCINAX* cf. *RUBER***, and ***PHYSALAEMUS ALBONOTATUS*** (Menwig Frog). **PREDATION**. Predatory events in nature are rarely published (Martins et al. 1993. Amphibia-Reptilia 4:273–296). Birds are generally reported preying on tadpoles (McAlpine et al. 2001. Herpetol. Rev. 32:183–184), but attacks on adult frog are less well documented (Brodie and Nussbaum 1987. Herpetol. Rev. 18:8–9; Master 1998. Herpetol. Rev. 29:164–165; Prado 2003. Herpetol. Rev. 34:231–232). Herein we describe four events of predation on three species of frogs by two birds, Whistling Heron (*Syrigma sibilatrix*, Ardeidae) and Great Kiskadee (*Pitangus sulphuratus*, Tyrannidae) observed during fieldwork in the Cerrado region of Central Brazil. The observations were made in a flooded field in Canaã Farm (20°40'30.4"S, 56°45'20.2"W), Municipality of Bodoquena, State of Mato Grosso do Sul, Brazil.

On three occasions were observed a Whistling Heron preying upon adult frogs in the edge of a flooded field: *P. albonotatus* (5 Dec 2000 at 1350 h), *S.* cf. *ruber* (6 Dec 2000 at 0834 h), and *S. fuscovarius* (6 Dec 2000 at 0944 h). *Physalaemus albonotatus* was hidden in the grass, and *Scinax* cf. *ruber* and *S. fuscovarius* were partially submerged along the edge of the flooded field. On 8 Dec 2000 at 1330 h we observed a Great Kiskadee prey upon *P. albonotatus*.

These birds forage in this temporary environment during the wet season, as many amphibians and fish use these flooded fields for reproduction. This environment is similar to that found in the Pantanal, where the ponds or flooded fields are used as foraging sites by many species of wading birds. Predation at these sites could represent a significant impact on populations of amphibians (Prado 2003. Herpetol. Rev. 34:231–232).

SPEA HAMMONDII (Western Spadefoot). **PREDATION.** Although predation on adult *Spea hammondii* by American Bullfrogs (*Rana catesbeiana*) has been previously documented (Morey and Guinn 1992. *In* Williams et al. [eds.], Endangered and Sensitive Species of the San Joaquin Valley, California. California Energy Commission. 388 pp.), published documentation of predation on larval *S. hammondii* by *R. catesbeiana* is lacking. On 25 March 2004 we collected and preserved two *R. catesbeiana* from a vernal pool near Orange Cove, Tulare County, California, USA (36°37'30"N, 119°16'00"W). Six *S. hammondii* larvae were recovered from the stomach of one *R. catesbeiana* (68 mm SVL) and five larvae were found in the other (64 mm SVL). Larval total length was 12–30 mm, although Gosner life stages of the larvae were not determined (Gosner 1960. Herpetologica 16:183–190). Several thousand *S. hammondii* and Western Toad (*Bufo boreas*) larvae were found within the pool from which the Bullfrogs were collected. Although this is the first published report of Bullfrog predation on larval *S. hammondii*, predation on larval *S. multiplicata* by *R. catesbeiana* has been observed at a temporary pond in the San Simon Valley along the Arizona/New Mexico stateline (Marie Simovich, pers. comm.).

STEFANIA EVANSI (Groete Creek Carrying Frog). **REPRODUCTION**. *Stefania evansi* is a large hemiphractine hylid frog restricted to Guyana from Kartabo and Groete Creek, westward to Mount Roraima at elevations of 10–1402 m (Duellman and Hoogmoed 1984. Misc. Publ. Mus. Nat. Hist. Univ. Kansas 75:1–39; MacCulloch and Lathrop 2002. Herpetologica 58:327–346). Like all other *Stefania* species, female *S. evansi* are known to carry eggs and juveniles exposed on their back, adhering to a mucus layer. As noted by Jungfer and Boehme (1991. Rev. fr. Aquariol. 18:91–96), very few female *S. evansi* carrying eggs or embryos are known. Only 4 cases of egg brooding females are known to us: Boulenger (1904. Proc. Zool. Soc. London 1904[2]:106) reported a female with 22 eggs from Groete Creek; Lang (1923. Nat. Hist. New York 24:467–478) reported a female with 24 eggs from Kamakusa; Jungfer and Boehme (*op. cit.*) reported a female carrying 21 juveniles from Ataro River; MacCulloch and Lathrop (*op. cit.*) reported a female with 11 near-term juveniles from the base of Mount Ayanganna.

Here we report a female (97.5 mm SVL—likely a new size record) carrying 25 eggs (Fig. 1). This large, striped morph female (Pattern B of Duellman and Hoogmoed, *op. cit.*), was collected by Festus Marco and two of us (PJRK and PB) at 1500 h on 24 June 2004 on rocks along a cascading stream in primary forest near Tukeit, ca. 150 m elev. in Kaieteur National Park, Guyana.

FIG. 1. Female *Stefania evansi* (IRSNB 13673), 97.5 mm SVL, carrying 25 eggs in the vicinity of Tukeit, Kaieteur National Park, Guyana.

The specimen was deposited in the herpetological collection of the Royal Belgian Institute of Natural Sciences (IRSNB 13673).

Duellman and Hoogmoed (*op. cit.*) indicated that reproduction of *Stefania* species is probably restricted to the wetter times of the year because most females carrying eggs have been collected in the rainy season. These authors also indicated that duration of development and egg brooding is unknown, but should probably require 2–3 months. According to the four literature records and this observation, female *S. evansi* carrying eggs were found in January, June, and late November while females with near-term juveniles were collected in October and early November. There are two distinct wet seasons in Guyana, the first "long" wet season occurring approximately from April to August and the second "short" wet season occurring approximately from November to January. Although breeding activity of *S. evansi* seems to be more common during the two rainy seasons, the available data do not indicate a rigid schedule of breeding.

We gratefully acknowledge the financial support of the Directorate General of Development Cooperation (Belgian Development Cooperation), and the National Science Foundation (NSF). Permission to conduct the herpetofaunal surveys was granted by the Prime Minister of Guyana, Honorable Samuel Hinds, and S. Nokta and I. Nathoo of the Guyana National Parks Commission, with research and collection permit 180604 BR 011 issued by the Guyana Environmental Protection Agency.

TESTUDINES

ACTINEMYS MARMORATA (Pacific Pond Turtle). **NEST ARCHITECTURE/ PREDATION.** Little has been published on the nest architecture of *A. marmorata*. Here we report nest architecture data and nest depredation characteristics of *A. marmorata* nest sites.

On 21 June 2004, approximately 8 depredated *A. marmorata* nests were observed in an approximately 0.202-ha exposed clearing along the western shoreline of a vernal lake in Lake County, California. The nests were concentrated 6–15 m from the high water mark, and the shoreline was characterized by low-stature non-native annual grasses and rocky outcrops. Most of the nests were situated within 3 m of the treeline, characterized by mixed evergreen forest with an understory dominated by manzanita. All of the nests detected showed evidence of depredation, including partially to fully excavated nest plugs, scattered shell remains, irregular shell fragment sizes, puncture holes, and broken edges pointing inward (Ashton et al. 2001. Ecology and Sampling Methods for the Western Pond Turtle. USDA Forest Service. Pacific Southwest Research Station, Redwood Sciences Laboratory. 60 pp.) (Fig. 1). Again on 31 July 2004, two additional depredated nests were observed in the same clearing. Although both showed signs of depredation, upon closer inspection, one nest contained a single undisturbed egg; the second contained 3 undisturbed eggs within the egg chamber. On a return visit 30 July 2005 to this same location, at least 15 depredated *A. marmorata* nests were recorded. All were easily detected based on signs of depredation. Several additional excavated holes and eggshell remains were detected in the immediate vicinity. Of the 15 confirmed nest sites, 7 were closely examined and data were recorded for each on soil compaction and nest characteristics (e.g., extent of depredation-related excavation, presence and number of shell remains, and presence of salient roots or stones within the nest chamber).

Following the study design of Witzell (2005. Herpetol. Rev. 36[1]: 59), each of the 7 nest sites was then carefully excavated by hand of all loose stones and debris, and casts were made of each

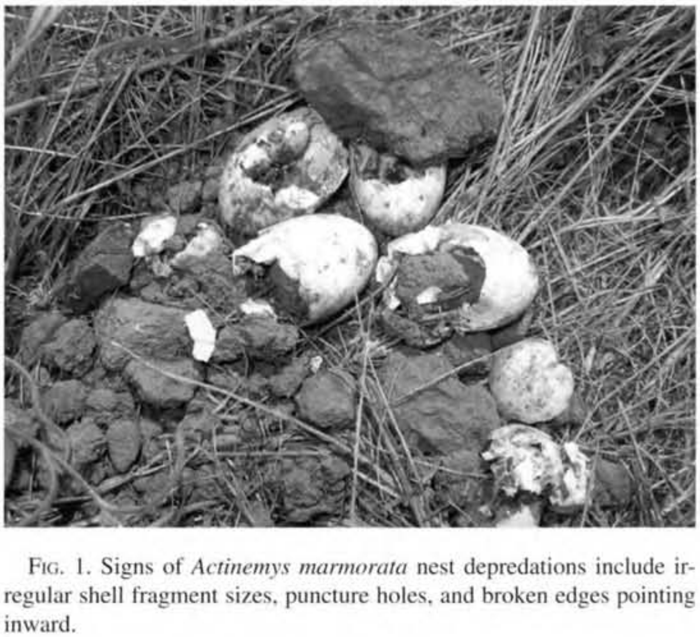

FIG. 1. Signs of *Actinemys marmorata* nest depredations include irregular shell fragment sizes, puncture holes, and broken edges pointing inward.

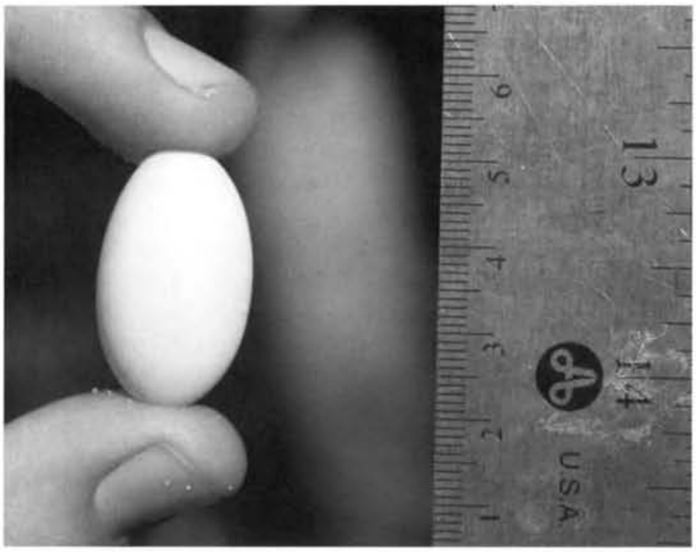

FIG. 2. Typical *Actinemys marmorata* egg recovered from aboveground.

nest chamber using a polyurethane insulating foam sealant. Once the casts had cured, each cast was hand-excavated. The minimum diameter of the neck, the maximum diameter of the egg chamber, and the depth of the egg chamber, measured from the top of the soil to the base of the chamber, were extrapolated from measurements of the casts. Soil compaction data was taken in the field with a single pocket penetrometer reading at the perimeter of each nest opening. One intact *A. marmorata* egg was recovered aboveground along the lake's perimeter close to the depredated nests; however, the immaculate condition of the egg suggests that it might not have been originally deposited inside of a nest chamber (Fig. 2). Those egg remains recovered from nest spoils were markedly soiled, likely due to soil moisture, cloacal mucus, or female turtle urine evacuated during nest construction.

Typical *A. marmorata* nests have been described as "flask or pear shaped" (Rathbun et al. 1992. Southwest. Nat. 37[3]:319–324) or "lightbulb/pear-shaped" (Holland 1994. The Western Pond Turtle: Habitat and History. Final Report. U.S. Department of Energy, Bonneville Power Administration. 303 pp.). Rathbun et al. (*op. cit.*) reported average dimensions of newly excavated, open, empty nests to be 6.5–8 cm deep, 6.5–7 cm maximum diameter across the egg chamber, and 3.5–4 cm maximum diameter across the neck. Holland (*op. cit.*) reported greater nest depths of between 9 to 12.5 cm.

At the Lake County study site, nests were roughly pear- or flask-shaped, but were offset in such a way as to exhibit bilateral rather than radial symmetry (Fig. 3). Several nest chambers were lined with large stones or crisscrossed by roots. The mean depth from the top of the soil to the base of the egg chamber was 8.5 cm ($\pm$ 1.2 cm), the mean minimum diameter of the neck was 22.1 cm ($\pm$ 2.8 cm), and the mean maximum diameter of the egg chamber was 22.6 cm ($\pm$ 2.6 cm). Soil compaction measurements taken at the perimeter of each nest opening ranged between 2 and 3.5 tons/sq ft. Between 1 and 6 eggshell remains that were greater than 50 percent intact were detected at each of the seven nest sites.

Although these architectural dimensions provide some insight into typical *A. marmorata* nests, it is important to point out that these dimensions are based solely on depredated nests sites. The wider neck apertures reported herein may be directly related to the excavation efforts of predators, for example. Given the diffi-

FIG. 3. Polyurethane nest molds of depredated *Actinemys marmorata* nests showing variation in size and shape.

culty involved in human detection of undisturbed nest sites, it is unknown what percentage of the total nests excavated in the 2004 and 2005 breeding seasons these depredated nests represent. If viable nest sites evaded detection by predators, this could be due to architectural dimensions that impede nest detection or depredation (i.e., greater nest depths).

Known predators of *A. marmorata* nests, including Striped Skunk (*Mephitis mephitis*), Coyote (*Canis latrans*), and Grey Fox (*Urocyon cinereoargenteus*) (Holland, *op. cit.*), are known to inhabit the study area. Other known nest predators, such as Raccoons (*Procyon lotor*) and Opossums (*Didelphis virginiana*) (Holland, *op. cit.*), are also likely residents of the area. However, no tracks or sign were evident to suggest what species might be depredating these nests. A study on the sensory perception of two known turtle nest predators, the Striped Skunk and Raccoon (Galois 1996. Turtle Nest Sensory Perception by Raccoon (*Procyon lotor*) and Striped Skunk (*Mephitis mephitis*): An Approach Through Discrimination Learning of Potential Nest Cues. Ph.D. dissertation. McGill Univ, Montreal. 105 pp.) has shown that these species in particular use visual, olfactory, and tactile cues to detect turtle nests. Among the potential cues that may attract such predators are female turtle urine and cloacal mucus deposited during nest construction, soil moisture (related to either urine/mucus or damp soils exposed during excavation), and differences in soil compaction between nest plugs and the surrounding soils (Galois, *op. cit.*).

Special thanks are in order to Sarah Anne Bettelheim and Jerry Roe for their help in the field.

THAYER**, 905 Dewing Avenue, Lafayette, California 94549, USA (e-mail: chthayer@yahoo.com); and **DANA E. TERRY**, 3550 Chestnut Ave. #1, Concord, California 94519, USA (e-mail: dterry@gmx.net).

ACTINEMYS MARMORATA (Pacific Pond Turtle). **NEONATES.** *Actinemys marmorata* historically ranged from Oregon to Mexico, mainly west of the Cascade–Sierra Nevada axis (Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Institution Press, Washington, D.C. 578 pp.; Jennings and Hayes 1994. California Dept. of Fish and Game, Rancho Cordova Final Report, Contract 8023, 260 pp.; Storer 1930. Univ. California Pub. Zool. 32:429–441). Populations of *A. marmorata* in California's San Joaquin Valley are declining and it is currently listed as a California Species of Special Concern (Jennings and Hayes, *op. cit.*). However, we know little about the natural history of this species, especially the neonatal stage. Here, I report dates and locations of neonatal *A. marmorata* captures.

I trapped *A. marmorata* at five sites in the northern San Joaquin Valley, California, USA, near the town of Los Baños. Los Baños Creek and Mud Slough North are in the China Island Unit of the North Grasslands Wildlife Area and Field 26, Field 42, and the Wasteway were in the Volta Wildlife Area. During 2003, Los Baños Creek was trapped from 4 April and 31 May, Mud Slough North from 5 April–17 June, Field 26 from 1 April–24 May, Field 42 from 22 June–22 July and the Wasteway from 21 May–10 August. I captured neonate *A. marmorata* in modified eel pot traps (Casazza et al. 2000. Herpetol. Rev. 31:91–92) set to survey for Giant Garter Snakes (*Thamnophis gigas*) with 50 mm openings on either end. I placed traps 10 m apart along banks and tied them to emergent vegetation or stakes and checked them daily. I batch marked all captured neonates by clipping two V-shaped notches in the marginal scutes on each side of the nuchal scute prior to releasing them at the site of capture. I used dial calipers to measure the midline carapace length of three initial captures.

Mid-line carapace length of the initial 3 turtles captured were 23.8, 26.7, and 27.5 mm with additional captures being of comparable size and within the size range given for hatchling *A. marmorata* (Buskirk 2002. Radiata 11:3–30). The shells of all hatchlings caught had not yet hardened, further indicating they had emerged from the nest that year (Ernst et al., *op. cit.*). Neonate capture dates are as follows: Los Baños Creek (12 [2 captures], 20, 23 [1 recapture] April); Mud Slough North (19 April, 11 May, 12 June); Field 26 (13, 15, 19, 20 [2 captures], 22, 24, 29 [2 captures] April, 1 [recapture], 14 May); Field 42 (5 June); the Wasteway (27 June). Additional species captured included Giant Garter Snakes, Common Garter Snakes (*Thamnophis sirtalis*), California Kingsnakes (*Lampropeltis getula*), Gopher Snakes (*Pituophis catenifer*), Bullfrog adults and tadpoles (*Rana catesbeiana*), and various unidentified voles, birds, minnows, and aquatic insects.

Because *A. marmorata* is a California Species of Special Concern it is critical to understand its life history and population dynamics. Earliest captures dates for one site in central California (Alameda Co.) are consistent with our findings (Buskirk, *op. cit.*). Jennings and Hayes (*op. cit.*) reported no recruitment in populations in California's Central Valley. However, later research reported young turtles were caught throughout the Central Valley of California suggesting recruitment in these populations (Germano and Bury 2001. Trans. West. Sect. Wild. Soc. 37:22–36). Understanding the habitat requirements and fates of neonates will improve future assessments of the age structure and stability of Central Valley populations.

I thank C. Dickert for project coordination, J. Brown, J. Schmidt, J. Sloan, and C. Sousa for help with field work, and G. Dayton, J. Sloan, and two anonymous reviewers for valuable comments. Project support was provided by California Department of Fish and Game, Los Baños Wildlife Area and the Grasslands Water District. Animals were handled under the authority of the California Endangered Species Act while I was employed with California Department of Fish and Game.

GLYPTEMYS INSCULPTA (Wood Turtle). **PREDATION.** Mutilation in the form of missing limbs and shell damage among Wood Turtles has been reported by Harding (1985. Herpetol. Rev. 16:30) and Farrell and Graham (1991. J. Herpetol. 25:1–9). Natural limb loss has been attributed to raccoons, and shell damage to various mammals. Here we report on an incident of predation upon a population of Wood Turtles during hibernation, and suggest that the most likely culprits were otters.

This southern New Hampshire population has been continuously

monitored (by DMC) since 1988 (see Tuttle and Carroll 1997. Chelon. Cons. Biol. 2:447–449, and 2003. Chelon. Cons. Biol. 4:656–663, for habitat descriptions), and nearly all of the turtles ($\approx$ 200 during that time) have been uniquely marked. Most have been located in multiple years and multiple times within a year. In late March of 1990, one adult male was found that had recently lost its left front and right hind legs, and a 6–8 yr-old was found dead with two large canine punctures through its carapace. Since 1990, only three instances of attempted predation have been noted, all consisting of limb loss by surviving subadults during the active season. During the spring of 2005, it became evident from observations of emerging turtles that there had been a major predation event during the previous hibernation period. Collections from 25 March 2005 until 11 July 2005 of 45 turtles included 21 (3 dead and 18 injured) that had been attacked. Turtles attacked had straight-line carapace lengths from 7.1 to 18.4 cm. The most common injury was the loss of part or all of one or two limbs, most commonly the front limbs (18 of 23 injuries). Additional undiscovered fatalities are likely, as several turtles that would normally have been located during the first two months after spring emergence had not been found by 11 July.

The portion of the study site where attacks occurred includes stretches of about 100 m and 300 m of two first-order streams ca. 75 m upstream of their confluence, which is in turn about 1.6 km distant from a small river. Undamaged turtles were found both upstream of the 100 m section (1, about 3 km) and downstream (5, about 0.4 km) of the confluence, indicating that this was a localized predation event. Otters (*Lutra canadensis*) are implicated from scats and prints in the area, and the fact that the turtles were submerged in up to 1.5 m of water. The hibernating turtles are often exposed on the bottom, frequently wedged between rocks, among woody debris, or among roots in the banks, which would make them easy prey for an underwater predator. Episodic otter predation upon hibernating Snapping Turtles (*Chelydra serpentina*) has been noted by Brooks et al. (1991. Can. J. Zool. 69:1314–1320), Park (1971. The World of the Otter. J. P. Lippincott Co., New York), and Surface (1908. Zool. Bull. Div. Zool., Pennsylvania Dept. Agric. 6:105–196), indicating that otters are capable of locating and killing hibernating turtles. In the case of Snapping Turtles, otters typically remove them from the water and eviscerate them ventrally, where the reduced plastron makes these turtles vulnerable. We speculate that the otters also removed the Wood Turtles from their hibernacula and took them to the stream banks (one of the three known fatalities was located on a stream bank), but were in most cases unable to do more than mutilate one or two limbs. The abandoned turtles would then have returned to the water.

HOMOPUS SIGNATUS (Speckled Padloper). **MAXIMUM MALE SIZE.** *Homopus signatus* is considered the world's smallest tortoise species. In the nominate subspecies *Homopus s. signatus* average straight-line carapace lengths (SLCL) of 87.9 mm for females (N = 35) and 77.9 mm (N = 36) for males have been reported (Loehr 2002. J. Herpetol. 36:378–389). The largest specimen recorded was a female with a SLCL of 110 mm; the largest male reported had a SLCL of 89.5 mm and a body mass of 113.0 g (Loehr, *op. cit.*). The southern subspecies *Homopus signatus cafer* is reportedly somewhat smaller. The SLCL range is 69.9–79.8 mm in males and 83.8–95.7 mm in females (Boycott 1986. J. Herpetol. Assoc. Afr. 32:10–16).

On 14 October 2004 we found a male *Homopus signatus cafer* hiding in a rock crevice in the vicinity of Lambertsbaai, South Africa. The SLCL was 93.0 mm, the straight-line plastron length was 71.9 mm, the maximum shell width was 66.2 mm, and the maximum shell depth was 35.1 mm. The body mass of the male was 128.2 g.

KINOSTERNON SUBRUBRUM SUBRUBRUM (Eastern Mud Turtle). **PREDATOR ESCAPE**. Known avian predators of *Kinosternon subrubrum* include crows and eagles (Ernst et al. 1994. Turtles of the United States and Canada, Smithsonian Inst. Press, Washington, DC; Mitchell 1994. The Reptiles of Virginia, Smithsonian Inst. Press, Washington, DC). Bald Eagles (*Haliaeetus leucocephalus*) are opportunistic foragers capable of exploiting a wide range of prey taxa (Buehler 2000. *In* A. Poole and F. Gill [eds.], The Birds of North America, No. 506, pp. 1–40. The Birds of North America, Inc., Philadelphia, Pennsylvania). Turtles have been documented as regular but uncommon prey primarily within the eastern portion of their breeding range (e.g., Bendell 1959. Can. Field Nat. 73:131–132; Broley 1947. Wilson Bull. 59:3–20; Ganier 1951. Migrant 22:37–39). Quantitative analyses of diets show that turtles account for < 2% of overall prey items taken by Bald Eagles (e.g., McEwan and Hirth 1980. Condor 82:229–231; Hunt et al. 2002. J. Raptor Res. 36:245–255). However, within the Chesapeake Bay, turtle shells are found with some regularity under eagle nests. An evaluation of prey remains collected from nest sites throughout the Chesapeake Bay over a five-year period documented the use of five turtle species (Clark 1981. J. Field Ornithol. 53:49–51). How eagles capture and consume these turtles is poorly understood, and we do not know if predation attempts are always successful. We observed predation of four turtle species during video monitoring of eighteen Bald Eagle nests in eastern Virginia during 2002 to 2003 (Markham and Watts, unpubl. data). Here we report on how one *K. subrubrum* escaped from attempted predation by this raptor.

During one observation on 17 April 2003 at an eagle nest on the York River, Virginia, an adult female eagle brought an adult *K. subrubrum* to her nest at 1114 h EST. She attempted several times to insert her beak enough between the plastron and carapace to grab onto the turtle's flesh. Attempts were made anteriorly and posteriorly over a period of 1 min 40 sec after which she abandoned the turtle and left it lying on its back. Sixty-nine minutes later the turtle turned over and walked to the edge of the nest and fell to the ground.

These observations document that at least some *K. subrubrum* brought to Bald Eagle nests can survive attempted predation. The

hinged plastron, the ability of this species to close up its shell or nearly so, and shell thickness prevented the eagle from being able to extract flesh with her beak. We suspect that Eastern Box Turtles (*Terrapene carolina*), with their ability to close their shells completely, are seldom found in eagle nests. Turtles of other species without this characteristic (e.g., *Chrysemys picta*, *Sternotherus odoratus*) are much less likely to survive predation from this large avian predator.

We thank the Miller family for allowing access to their property. This study was financially supported by grants from the College of William & Mary, the Mary and Daniel Loughran Foundation, the Northern Neck Audubon Society, the Virginia Society of Ornithology, the Williamsburg Bird Club, and the Center for Conservation Biology.

MACROCHELYS TEMMINCKII (Alligator Snapping Turtle). **FEEDING BEHAVIOR**. Observations of lingual luring in Alligator Snapping Turtles are common in captive specimens but apparently rare in the wild (Ernst et al. 1994. Turtles of the United States and Canada, Smithsonian Institution Press, Washington, DC. 578 pp.; Pritchard 1989. The Alligator Snapping Turtle: Biology and Conservation, Milwaukee Public Museum, Milwaukee, Wisconsin. 104 pp.). Herein, we provide an account of luring by an adult male Alligator Snapping Turtle in a clear-water, riverine environment. The turtle was observed by WRH on 21 September 2004 feeding (i.e., luring using its tongue appendage) at the bottom of the Eleven Point River in Randolph County, Arkansas, USA (N36.39383, W91.11433; NAD 27 CONUS) while we were scuba diving. The turtle was located in ca. 4 m of water and was positioned midstream on the gravel/bedrock interface, which is a typical characteristic of a lateral scour pool. Visibility was ca. 3 m, and the water temperature was 20°C. (The discharge rate was approximately 1000 ft^3/sec—USGS, Ravenden Springs reporting station.) The turtle's head was facing directly upstream with mouth gaping. The ventral portion of his body was resting partially on bedrock and partially on cobble/gravel; one set of his posterior claws was embedded into the gravel, and the other set was grasping to secure a hold on the bedrock. The anterior claws were positioned in a similar manner. The carapace was completely exposed, yet was well camouflaged within the surrounding substrate.

The turtle was captured by hand by WRH and was taken to the herpetology lab at Arkansas State University for photographing and processing. This turtle had a mass of 14.1 kg, a straight-line carapace length of 37.3 cm, a pre-anal tail length of 10.4 cm, and a post-anal tail length of 29.0 cm. An encrypted (AVID® Identification Systems, Inc., Norco, California) PIT (passive integrated transponder) tag was implanted within the dorsal musculature of the tail. The turtle was released back into the river at the point of capture on 23 September 2004.

LACERTILIA

ANNIELLA PULCHRA PULCHRA (Silvery Legless Lizard). **HABITAT.** Except for a questionable account from Redwood Canyon, Marin County (Rivers 1902. Bull. So. California Acad. Sci. 1:27; Jennings and Hayes 1994. Amphibians and Reptile Species of Special Concern in California. California Department of Fish and Game, Rancho Cordova, California. 255 pp.), the range of *Anniella pulchra pulchra* is known to extend north to the south bank of the San Joaquin River, California, along the river's downstream approach to the San Francisco Bay Delta. Although the species is known to occur in the dunes at the Antioch Dunes National Wildlife Refuge, the East Bay Regional Park District Legless Lizard Preserve, and at scattered locations throughout Antioch, Oakley, and Brentwood, Contra Costa County, little has been published on its habitat requirements in this region beyond the treatment of Miller (1944. Ecol. Monogr. 14:271–289) and the species overview in Jennings and Hayes (*op. cit.*). As both a California Species of Special Concern and a Federal Species of Concern, more complete information on habitat conditions at the northern end of its range are needed. Hence, we help fill that gap with a report of the recent occurrence of 19 individuals in the Antioch/Oakley area, and describe a heretofore undescribed vegetation community—Oakley sand stabilized interior dunes—within which we have recorded this species.

On 28 January 2004, during herpetofaunal surveys of a 2.71-ha portion of sand dune ca. 2.4 km E of the City of Oakley, we found a single *A. p. pulchra* beneath a piece of 0.6 × 1.8 m corrugated sheet metal. A follow-up visit on 29 January 2004 revealed a second *A. p. pulchra* ca. 90 m north of the first sighting beneath a pile of ca. 15 pieces of similarly sized corrugated sheet metal. Also observed on this occasion were a *Coluber mormon* and a *Pituophis catenifer catenifer* between sheets situated higher in the pile. In both these cases, *A. p. pulchra* was observed above ground (i.e., not buried within the sandy substrate) between the substrate-cover interfaces, but each was quick to burrow into the sandy substrate when exposed.

At this same dune, focused follow-up surveys were conducted on 28–29 June and again on 26 July 2004. Focused surveys consisted of excavating target areas with habitat components thought to be important to *Anniella* (e.g., sandy soils in proximity to trees and shrubs and associated leaf litter; see Miller, *op. cit.*) and sifting the sands with a hand cultivator tool. Excavations reached depths of up to 60 cm and were generally confined within the drip-line of trees and consisted of trenches that extended up to 6 m from the trunks. We encountered 11 more *A. p. pulchra* at depths between 15 and 30 cm, typically close to the horizon between

deeper moist sand and overlying dry sand. All occurrences were within 90 m of the January occurrences and located beneath the drip-lines of Coast Live Oaks (*Quercus agrifolia*), estimated by CHT to be 50 to 200 years in age.

On 17 March 2005, we focused surveys on an adjacent 0.67-ha portion of dune immediately southwest of the dune searched between January and July 2004. This second location had a well-developed stand of Silvery Bush Lupine (*Lupinus albifrons*) with an understory of non-native annual grassland dominated by such species as Hairy Vetch (*Vicia villosa*), brome grasses (*Bromus* spp.) and filaree (*Erodium* spp.). One *A. p. pulchra* was found beneath a fine layer of sand covered by a discarded steel automobile hood ca. 3 m from the nearest lupine. On 25 April 2005, we found 4 more *A. p. pulchra*. Three were detected by raking the sand beneath a pile of three 1.2×2.4 m plywood sheets, and the fourth was partially exposed in sand underneath a $15 \times 15 \times 121$ cm fencepost.

These *A. p. pulchra* occurrences are unique in that the dune complex in which they were found supports a vegetation assemblage that has been poorly recognized and is yet to be adequately described. Holland (1986. Preliminary Descriptions of the Terrestrial Natural Communities of California. California Department of Fish and Game, Sacramento, California. 156 pp.) recorded a similar vegetation assemblage, but based on his specific location on the bank of the San Joaquin River and his inclusion of two plants, Antioch Dunes Evening Primrose (*Oenothera deltoides* var. *howellii*) and Contra Costa Wallflower (*Erysimum capitatum* var. *angustatum*), endemic to a single locality, this description appears to be specific to the Antioch Dunes and effectively excludes other dunes in the region.

In the Oakley area, loose to consolidated sandy soils generally mapped as Delhi sand, Piper sand, and Piper fine sandy loam (USDA 1977. Soil Survey of Contra Costa County, California. Natural Resources Conservation Service) characterize this habitat, which we refer to here as Oakley sand stabilized interior dunes. These soils are on sites often referred to locally as "sand mounds," and are widely distributed in the area. The presence of locally uncommon native plant species including California Croton (*Croton californicus*), Desert Evening Primrose (*Oenothera deltoides* ssp. *cognata*), Small Evening Primrose (*Camissonia* spp.), Slender Buckwheat (*Eriogonum gracile* var. *gracile*), Blue Head Gilia (*Gilia capitata* ssp. *staminea*), Kellogg's Tarweed (*Deinandra kelloggii*), and Valley Lessingia (*Lessingia glandulifera* var. *glandulifera*) characterize the vegetation. The dune flora also often supports the aforementioned *Q. agrifolia* and *L. albifrons*, which, unlike the other plants listed, are also common on other soil types in the region.

Similar, isolated pockets of dune habitat were also present 0.8 km north of the described dune complex, but we observed no *A. p. pulchra* during two months involving over 70 h of surveys and spot checks in January–February 2004. Based on the 1977 NRCS soil survey maps, these outlier dunes were once connected to the eastern boundary of the greater dune system typical of the Antioch/ Oakley area. When compared to the NRCS soils survey maps, agricultural fields, well-trafficked roads, irrigation canals, and urban sprawl isolate most such remaining dune habitat.

Documentation of *A. p. pulchra i*n Contra Costa County is recorded from the 1930s to the present, and includes 7 specimens collected in Antioch and a single specimen collected in Oakley (California Academy of Sciences); 36 specimens from 8 indeterminate locations in Oakley, Antioch, and Brentwood (Museum of Vertebrate Zoology); and three Contra Costa County locations identified in the California Natural Diversity Database (www.dfg.ca.gov/whdab/html/cnddb.html), which includes the East Bay Regional Park District Legless Lizard Preserve where on 26 April 2004, MPB found a freshly killed specimen outside of the preserve's perimeter with a puncture wound to its abdomen (CAS 228525).

Based on our observations of the present distribution of sandy soils and plants associated with the Oakley sand stabilized interior dunes vegetation community, together with our *A. pulchra pulchra* occurrences reported here, we surmise that the museum and database records noted from Contra Costa County occurred in locations supporting this habitat type. Understanding the degree of linkage between this association and *A. p. pulchra* distribution will help elucidate *A. p. pulchra* habitat requirements at the northern end of its range.

Special thanks are in order to Kristi Asmus, Heath Bartosh, Ted Hermansen, Mike Ireland, Veronica Wunderlich, and Yin Lin Zhang for their help in the field.

ANOLIS PULCHELLUS (Grass Anole). **NECTIVORY.** Nectar feeding has previously been reported in anoles (e.g., Liner 1996. Herpetol. Rev. 27:78). Perry and Lazell (1997. Herpetol. Rev. 28:150–151) argued that, though episodic, it is more common that usually thought, and recent reports (Campbell 2000. Herpetol. Rev. 31:239; Echternacht et al. 2000. Herpetol. Rev. 31:173; Rios-López 2004. Herpetol. Rev. 35:386; Townsend 2004. Herpetol. Rev. 35:141–142) support that view. Here we report on another such case.

On the afternoon of 24 September 2005, we observed an adult (ca. 4.5 cm SVL) male *Anolis pulchellus* licking at a button-like structure near the base of the leaf of a small *Leucaena leucocephala* tree (Leguminosae). The lizard was about 1 m above the ground and the behavior continued for about a minute. Although nectar was not apparent to the naked eye, these structures are known to be extrafloral nectaries (Minu 1991. Acta Botanica Indica 19:49–54).

This is but the second report of lizards using extrafloral nectaries; the first (Rios-López 2004. Herpetol. Rev. 35:386) occurred in a closely related lizard species of similar size that also occurs on the Puerto Rico bank. Anoles also occasionally engage in outright herbivory (e.g., Lazell and Mitchell 1998. Herpetol. Rev. 29: 237), and episodic nectivory also occurs in other lizard clades (e.g., Perry and Ritter 1999. Herpetol. Rev. 30:166–167).

Support for this project was provided by The Conservation Agency and Texas Tech University. This is manuscript T-9-1082 of the College of Agricultural Sciences and Natural Resource Management, Texas Tech University.

ANOLIS SAGREI (Brown Anole). **TESTICULAR PATHOLOGY**. At 0822 h on 18 April 2002, GN collected a male *Anolis sagrei* (55 mm SVL, 4.7 g) in an irrigation ditch in an agricultural area of Santzepu, Shuisan District, Chiayi County, Taiwan (23°25'42"N, 120°28'55"E datum: WGS84; elev. 60 m). A paved road and a rice paddy bordered the sides of the ditch. The lizard was emaciated, and easily caught.

Dissection revealed that the stomach contained a hymenopteran, but no abdominal fat was present. The liver index (liver weight/SVL × 100) of this lizard was 0.236, slightly lower than the average (0.268) of the other males collected in that month. It was also noted that the right testis was a grayish-black color, much reduced in size (3.5 mm long, 2.9 mm wide, 0.05 g), and hard, while the left testis was a normal dark mustard color and appeared to be in a normal condition and size (6.2 mm long, 5.2 mm wide, 0.12 g). Both left and right testes, as well as the liver, were fixed in 10% formalin, embedded in wax, sectioned at 5μ and stained with Ehrlich's hematoxylin and eosin (HE), Periodic-Acid-Schiff (PAS) and Ziehl-Nielsen (ZN) stains. The liver was very dark in color and had white nodules on the ventral side near the gallbladder, but no abnormalities were observed during the histological examination. Sections of the left testicular adnexa (Fig. 1) revealed a necrotizing granuloma, composed of central necrosis surrounded by epithelioid to polygonal histiocytes and fibrosis, but adjacent testicular tissue did not appear to be affected and was undergoing spermatogenesis. Sections of the right testis (Fig. 2) revealed only a residual granuloma without any normal testis and adnexal tissue. The granuloma was composed of central necrotic eosinophilic granular materials, surrounded by plump histiocytes. A ring of

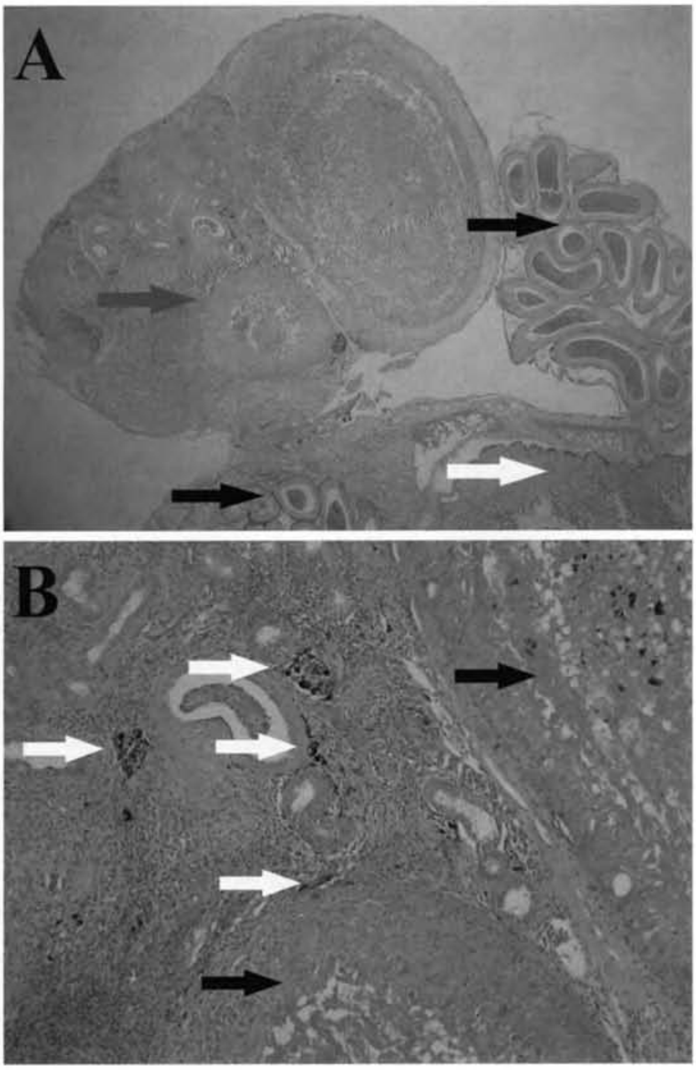

FIG. 1. **A** – A section of the left testicular adnexa (40× magnification, HE stain). Note the lesion in the upper left hand portion of the image; and the spermatozoa in the epididymis (center lower and right hand portion of the image); as well as the reproductively active seminiferous tubules (the lower right hand corner of the image). **B** – The same section (100× magnification, HE stain); note the melanin in the center of the nodule and the necrosis in the lower right hand and upper right hand corner of the image.

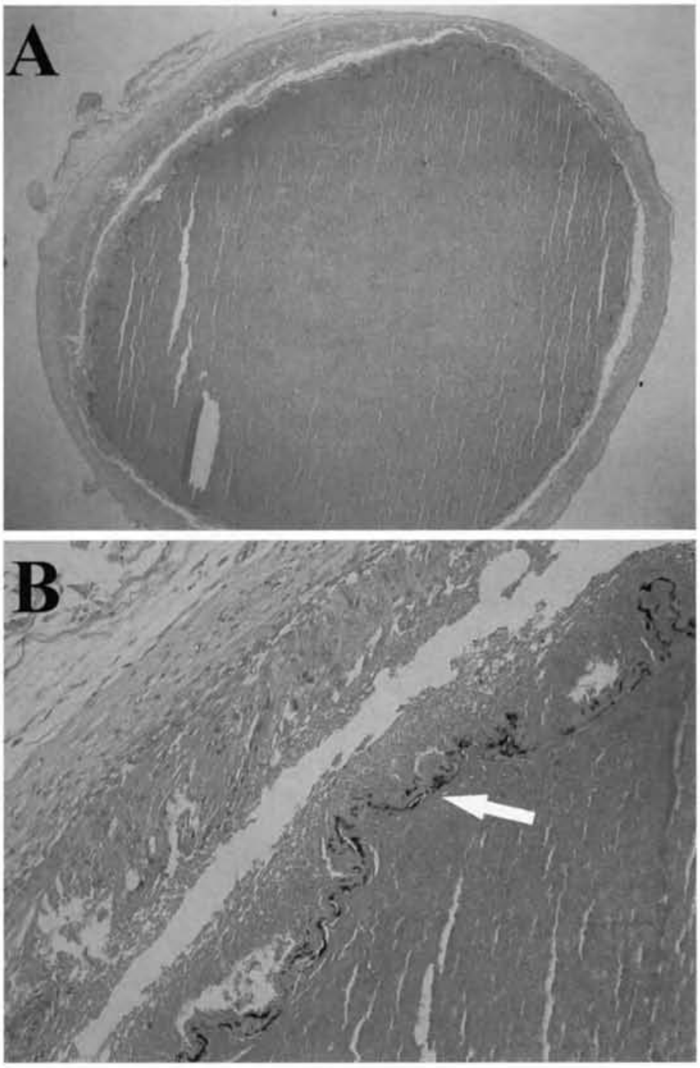

FIG. 2. **A** – A section of the right testis without any normal testis and adnexal tissue (40× magnification, HE stain). **B** – Note the melanin that is surrounding the necrotic tissue (200× magnification, HE stain).

melanin surrounding the necrotic focus suggests that the lesion originated from the testicular adnexa.

In sections of the left and right testes, as well as the liver, treated with PAS and ZN stains, no fungi or acid-fast bacilli were observed; thus, the exact cause of these lesions is uncertain. Since this *A. sagrei* was part of other studies, necessitating that the organs be treated as needed for those investigations (i.e., fixation), culture of fungi and bacteria was not possible. This appears to be the first report of such lesions in *A. sagrei* from Taiwan.

We would like to express our gratitude to Mei-Hsiu Cheng and the other laboratory technicians of the Chiayi Christian Hospital cytology laboratory for preparing the microscope slides, and to Dr. Rod Suepaul for his suggestions.

COLEONXY BREVIS (Texas Banded Gecko). **COLOR PATTERN.** *Coleonyx brevis* is a nocturnal gecko restricted to the northern and east-central parts of the Chihuahuan Desert, the western and southern edge of the Balconian Biotic Province and most of the Tamaulipan Biotic Province of Texas and Mexico (Blair 1950. Texas J. Sci. 2:93–117); in México, the species occurs in northeastern Chihuahua, most of Coahuila, north and central Nuevo León, and small portions of northwestern Tamaulipas and northeastern Durango (Bartlett 1996. Reptiles 4:48–67; Dixon 1970. Cat. Amer. Amphib. Rept. 88.1–88.2; Stebbins 2003. A Field Guide to Western Reptiles and Amphibians. 3rd ed. Houghton Mifflin Co., New York. 353 pp.). The species is small (maximum SVL = 59 mm [females], 56 mm [males]), and the typical dorsal pattern consists of a series of small spots alternating with dorsal bands (Dial and Grismer 1992. Syst. Biol. 41:178–195; Dixon 1970, *op. cit.*; Klauber 1945. Trans. San Diego Soc. Nat. Hist. 10:133–216). To our knowledge, no aberrant color patterns in *Coleonyx* involving longitudinal dorsal stripes have been reported (see Klauber 1945, *op. cit.*; Dyrkacz 1981. SSAR Herpetol. Circular 11:1–31). Hence, we describe a *C. brevis* with a longitudinal-striped pattern from central Nuevo León, Mexico.

FIG. 1. An unusual pattern in a juvenile male *Coleonyx brevis* from El Carmen, Nuevo Leon, México.

On 22 April 2004, while conducting a herpetological survey on the slopes of Cerro Minas Viejas in a submontane matorral biotic community in the municipality El Carmen (25°56'57.5"N, 100°21'40.9"W, datum: NAD27; 556 m elev.), we found a subadult male *C. brevis* (41 mm SVL; 26 mm tail, 1.8 g) under a 17 x 15 cm rock. It lacked typical dorsal banding pattern on the body, having instead longitudinal stripes (Fig. 1), but the tail had the typical banding pattern. The lizard was photographed and released. Other reptile species are known to have banded and striped morphs (Fox et al. 2003. Lizard Social Behavior. Johns Hopkins Univ. Press, Baltimore, Maryland. 464 pp.; Zug et al. 2001. Herpetology: An Introductory Biology of Amphibians and Reptiles, 2nd. edition. Academic Press, San Diego, California. 630 pp.), but the significance of the striped morph in *C. brevis* will require an understanding of its population-level frequency and its relationship to different habitat conditions.

Submitted by **DAVID LAZCANO** (e-mail: dvlazcano@hotmail.com), **CRISTINA GARCIA DE LA PEÑA** (e-mail: crisgp15@yahoo.com), and **GAMALIEL CASTAÑEDA** (e-mail: biosg@yahoo.com), Universidad Autónoma de Nuevo León, Facultad de Ciencias Biológicas, Laboratorio de Herpetología, Apartado Postal - 513, San Nicolás de los Garza, Nuevo León, C.P. 66450, México.

CTENOTUS SPALDINGI (NCN). **NEST SITE DISTUBANCE; HATCHING.** The scincid genus *Ctenotus* is a large group of diurnally active insectivorous lizards (Cogger 2000. Reptiles and Amphibians of Australia. Reed Publishing, Sydney, Australia. 808 pp.) that reach among the highest species diversities of any terrestrial vertebrate (Pianka 1986. Natural History of Desert Lizards. Princeton University Press, Princeton, New Jersey. 222 pp.). Still, little is known about the nesting or potential cues responsible for hatching in most members of this genus. Hence, here I report an observation of nesting habitat, nest disturbance and subsequent hatching of the species *Ctenotus spaldingi*.

During fieldwork in the desert uplands of northeastern Queensland, I uncovered a nest containing 5 eggs (mean dimensions; 12 × 11 mm; N = 5) positioned against the wall of a pitfall bucket while checking an established trapping grid. The nest was situated in Mitchell grass (*Astrebla* sp.)-dominated black soil plains habitat (Morgan 1999. *In* Sattler and Williams [eds.], The Conservation Status of Queensland's Biogeographical Ecosystems, pp. 10/1–10/35. Environmental Protection Agency, Brisbane, Queensland, Australia). The nest was relatively shallow with a 4.5-cm covering of dried soil with the entrance to the nest connected to a hole leading into a nearby crack in the soil. In the uncovering process, one of the eggs was inadvertently damaged, and an attempt was made to move the eggs to a suitable incubation site. While moving the remaining eggs, one egg began to hatch;

in just over 4 min, it had fully emerged from its egg, at which point the hatchling was still attached to its yolk sac via the umbilicus. The time between when the eggs were uncovered to when the hatchling fully emerged from its egg was ca. 7 min. Remaining eggs were transferred to a small plastic bag with moist grass and leaves and allowed to incubate at an air temperature averaging 25°C; the remaining viable eggs hatched over the next 4 days. The clutch size and nest depth documented in this observation of *C. spaldingi* is similar to that reported in another study of *Ctenotus* (clutch size: 4–6 in *C. robustus*; 2–6 in *C. taeniolatus*; nest depth: 5 cm in *C. robustus*; 4 cm in *C. taeniolatus*; Taylor 2005. Aust. J. Zool. 52:649–666). However, I am unaware of other reports suggesting that nest disturbance may induce hatching in the genus *Ctenotus*.

GAMBELIA WISLIZENII (Long-nosed Leopard Lizard). **PREDATION.** Previous observations of *Gambelia wislizenii* have revealed that this lizard preys on large invertebrates and small vertebrates, including other lizards and mammals (e.g., McCoy 1967. Amer. Midl. Nat. 77:138–146; Parker and Pianka 1976. Herpetologica 32:95–114; Pietruszka et al. 1981. J. Herpetol. 15:249–250). Although herpetologists might have often witnessed *G. wislizenii* feeding in the wild, photodocumentation of the predation process is lacking. Here we photodocument the details of a *G. wislizenii* predation event on *Uta stansburiana* from southern Utah, USA.

At 1457 h on 12 May 2004, we witnessed an adult (> 90 mm SVL) *G. wislizenii* (a male based on lack of nuptial coloration) seize an adult (> 40 mm SVL) *U. stansburiana* (also a male based on the bluish throat color and the intensity of the lateral spot behind the forelimbs) and digitally photographed the encounter. The incident occurred just a few meters north of the newly restored Paria Canyon Movie Set in Grand Staircase-Escalante National Monument, Kane County (37°14.237'N; 111°57.498'W; elev. 1450 m). Triassic-age rocks around the site weather readily, producing abundant soft alluvium in the valley. Consequently, sagebrush grows relatively densely, providing ample shade and shelter among rocks and sandy areas for basking.

Our photodocumentation omits the first 30 sec of the assault. During this phase, the *G. wislizenii* grasped its prey by the neck and immobilized it by repeated shaking and visibly clenching its jaw. This process continued, increasingly less vigorously, until the *U. stansburiana* stopped moving. The *G. wislizenii* then rapidly rotated its prey and ingested its entire torso, head first and belly up, within a minute (Figs. 1A–B). Ingestion of the torso was followed by a minute-long pause. The final effort consisted of swallowing the tail. This appeared to be a strenuous process during which the leopard lizard repeatedly contorted its body (Fig. 1C), presumably to roll up the food item in its stomach. During ingestion, our observation distance was 3–4 m. Following prey ingestion, the *G. wislizenii* noticeably slowed its movements, and it tolerated an even closer approach to a distance of 2 m. Based largely on the camera's digital clock, the entire progression from initial attack to completion of prey ingestion took about 3.5 min.

A literature search revealed that detailed descriptions of predation of *Gambelia* spp. are rare since most food habits studies fo-

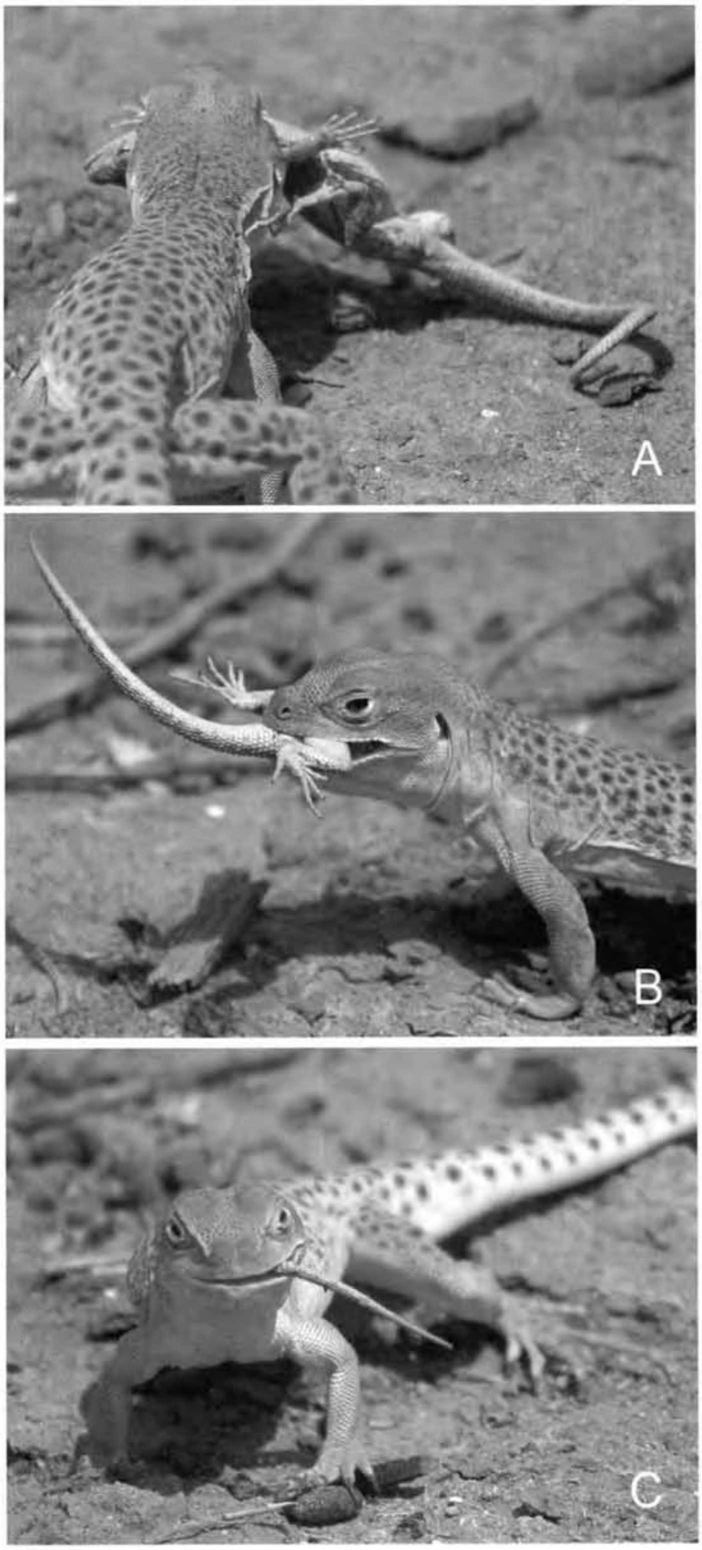

FIG. 1. A) Seven seconds after the observation began, the *Gambelia* has immobilized the *Uta* with repeated shaking and jaw clenching. B) Fifty-three seconds after the observation began, the prey is swallowed head first and belly up. C) To swallow the tail of its prey, the *Gambelia* repeatedly contorts its body; 149 sec after the observation began.

cus on the stomach contents of these lizards (e.g., Knowlton and Janes 1932. Ohio J. Sci. 32:467–470, Knowlton and Janes 1934. Copeia 1934:10–14, Knowlton and Thomas 1936. Copeia 1936:64–66, Milstead and Tinkle 1969. Am. Midl. Nat. 81:491–499). *Gambelia* is a fast, aggressive and tenacious predator that can capture prey running at full speed (Tanner and Krogh 1974. Herpetologica 30:63–72). However, the time needed for swallowing seems to vary greatly. A male *G. sila* caught and swallowed a conspecific hatchling "within a few seconds" (Germano and Williams 1994. Herpetol. Rev. 25:26–27), but the consumption of a pocket mouse *Perognathus* by a juvenile female *G. wislizenii* necessitated more than 1.5 h (Pietruszka et al. 1981. J. Herpetol. 15: 249–250). Large prey is swallowed with the aid of bending movements of the head and body, whereas small prey is masticated before ingestion (Montanucci 1956. Herpetologica 21:270–283).

GERRHONOTUS LIOCEPHALUS (Texas Alligator Lizard). **MORTALITY**. In México, forest fires occur primarily over two seasonal intervals. One season, which runs January to June, applies to the entire country save the northeast; the other, which begins in May and ends in September, applies to northeastern México. Both coincide with the dry season (SEMARNAP, 2000. Texto Guía Forestal. Subsecretaría de Recursos Naturales, Dirección General Forestal-SEMARNAP. México, D.F., 150 pp.). Forest fires have the potential to negatively affect forest faunas, and in particular, amphibians and reptiles (Bury 2004. Conserv. Biol. 18:968–975). Fire-induced formation of light gaps in forest canopies can favor certain reptiles, but reptiles may have greater difficulty finding refuge in fire-affected sites (Bury, *op. cit.*; Ernst et al. 1995. Herpetol. Rev.26:185–187). However, few data exist indicating the vulnerability of reptiles. Hence, here we provide an observation from Nuevo Leon, México implying that *Gerrhonotus liocephalus* might sometimes be at risk from forest fires.

During a visit to the central part of the Parque Ecológico Estatal Chipinque, in an area known as El Empalme (25°36'16.0"N, 100°21'06.0"W, datum: NAD27, elev. 1270 m) on 25 April 1998, we found an adult female *G. liocephalus* (141 mm SVL; 36 mm tail with a 20 mm regenerated piece; 33.5 g) that died probably due to a forest fire that had passed through the area over the interval 9–22 of April 1998 (fire information online at http://www.jornada.unam.mx/1998/04/11/incendios.html and http://www.horacero.com.mx/130_edicion/30130.html). This female lacked digits on its left front foot, and all metatarsals and phalanges were missing on its right front foot. All digits on the hind feet were incomplete, as the outer portion of each digit up to at least the second phalange was missing. Moreover, the dorsal scales were much darker than normal and sloughed off in alcohol after only two days of preservation, suggesting the lizard was exposed either to fire directly or to a hot substrate. Our visit to the site occurred two days after the fire was brought under control, which suggests that this animal survived the fire but succumbed from fire-related injuries. In this same area we also found under a rock a specimen of *Plestiodon brevirostris pineus* that had not been affected. More information on the vulnerability of fire to reptiles will be needed to determine whether demographic consequences to this sort of mortality exist.

The *G. liocephalus* (UANL 5532) was deposited in the herpetological collection of the Universidad Autonoma de Nuevo Leon, Facultad de Ciencias Biologicas.

HOPLODACTYLUS MACULATUS (Common Gecko). **SOCIAL ASSISTANCE**. Cooperation, especially parental care, is a significant life history component in many vertebrates (Clutton-Brock 1991. The Evolution of Parental Care. Princeton University Press, Princeton. 368 pp.). However, documentation of parental care in reptiles is sparse, having been reported or inferred for only 3.4% of lepidosaurians (Somma 2003. Parental Behavior in Lepidosaurian and Testudinian Reptiles: A Literature Survey. Krieger Publishing Company, Malabar, Florida. 174 pp.). Moreover, reports of parental care among lepidosaurians are taxonomically biased towards snakes (Shine 1988. *In* Gans and Huey [eds.], Biology of the Reptilia. pp. 275–329. Alan R. Liss, New York), and among lizards are biased towards skinks (Somma, *op. cit.*). Of the nearly 1000 recognized species of geckos (Suborder Gekkota; Pianka and Vitt 2003. Lizards: Windows to the Evolution of Diversity. University of California Press, Berkeley. 333 pp.), parental care has been reliably documented in only 21 (all in the Family Gekkonidae; Somma, *op. cit.*). Further, reports of parental care of post-hatching juveniles (as opposed to eggs) are even less common (Shine, *op. cit.*; but see Evans 1959. Copeia 1959:103–110; O'Connor and Shine 2004. Anim. Behav. 68:1361–1369 for exceptions). Hence, here we report observations of juvenile *Hoplodactylus maculatus* using adult conspecifics to aid in dispersal to foraging grounds from a communal retreat site.

Hoplodactylus maculatus, moderate-sized (to 82 mm SVL) nocturnal geckos endemic to New Zealand (Gill and Whitaker 2001. New Zealand Frogs and Reptiles, David Bateman, Auckland, New Zealand. 112 pp.), are known to form large diurnal aggregations (Hare and Hoare 2005. Herpetol. Rev. 36:179). During a two-week period in November 2004 (austral spring), we observed and video-recorded nocturnal emergence behavior of a diurnal aggregation of ~100 individual *H. maculatus* on Stephens Island, Cook Strait, New Zealand (40°35'S, 173°55'E; elev. 200 m). Geckos (adults, sub-adults, and < 1-month-old neonates) emerged singly from their retreat site at dusk (~2030 h NZDT) from two exits and were seen moving in progression along branches, and between coastal trees to reach the canopy, presumably to forage. Neonate geckos were observed travelling with 1–2 adults on several occasions. More importantly, however, we observed neonate geckos using the body of adult geckos that were bridging the gap between twigs of different trees to make arboreal crossings (Fig. 1).

FIG. 1. An adult *Hoplodactylus maculatus* (large animal in center) forming an arboreal bridge between the twigs of adjacent trees over which a juvenile conspecific (on left) has just crossed.

Two neonate geckos observed attempting to cross from one tree to another without the assistance of adult geckos were unsuccessful in their endeavors to reach the next tree. In a location, such as Stephens Island, with a high density of ground-dwelling nocturnal predators of geckos (Tuatara, *Sphenodon punctatus*, known to prey on *H. maculatus* [Walls 1981. New Zealand J. Ecol. 4:89–97], occur at an average density of 2015/ha in forest habitat; Carmichael et al. 1989. New Zealand J. Zool. 16:269), the risk of mortality as a consequence of falling to the ground during arboreal crossings, or using the ground to move between trees, is likely to be high.

We cannot confirm relatedness of adult and neonate geckos seen travelling together, but our observations provide evidence of social interaction between *H. maculatus* of differing ages and tolerance of neonates by adults. The level of social assistance seen in *H. maculatus* has rarely been reported among reptiles (reviewed by Chapple 2003. Herpetol. Monogr. 17:145–180), and particularly geckos (Shine, *op. cit.*; Somma, *op. cit.*).

Despite *Hoplodactylus maculatus* being frequently observed in diurnal aggregations (Hare and Hoare, *op. cit.*) nocturnal emergence behaviors associated with these aggregating geckos have not been reported. Living in dense aggregations might necessitate dispersal preceding their diel activity period to forage effectively. We encountered geckos in the surrounding coastal forest throughout the night at distances of > 10 m from their diurnal retreat site. Social assistance among conspecific nocturnal geckos might facilitate foraging and predator avoidance of neonates within social aggregations. Clarifying the relatedness among aggregations of individuals and the purpose and extent of social assistance might significantly contribute to knowledge of sociality and parental care in reptiles.

We thank Kelly Hare for comments on the draft. Our research was conducted with New Zealand Department of Conservation approval.

HOPLODACTYLUS MACULATUS (Common Gecko). **LONGEVITY**. The New Zealand lizard fauna is characterized by extreme longevity, low reproductive output, and high species diversity for its size when compared with other temperate regions in the world (Bannock et al. 1999. New Zealand J. Ecol. 23:101–103; Cree 1994. New Zealand J. Zool. 21:351–372). Longevity estimates for free-living *Hoplodactylus* geckos (*H. duvaucelii* and *H. maculatus*) are currently at least 36 years (Bannock et al., *op. cit.*; Thompson et al. 1992. J. Royal Soc. New Zealand 22:123–130).

Determining the maximum life span for wild geckos is difficult. Growth rate data cannot be used to age geckos once they attain maturity, a process which can take up to eight years (Sheehan et al. 2004. New Zealand J. Zool. 31:109). Longevity estimation therefore requires that identifiably marked individuals be recaptured over long time intervals. Because mark-recapture studies are not usually conducted over decades, return visits to sites where geckos were marked in previous studies provide the only alternative means of extending longevity records. We report here on a visit to one such site and the resulting recapture of five *H. maculatus* of extreme age.

The 3.7-ha Motunau Island in North Canterbury (43°03'S, 173°04'E) supports large populations of seabirds and lizards—the nocturnal gecko *H. maculatus* and the diurnal skinks *Oligosoma lineoocellatum* and *O. nigriplantare polychroma*. *Hoplodactylus maculatus* comprises a cryptic species complex (Daugherty et al. 1994. New Zealand J. Zool. 21:317–323) and the taxon present on Motunau Island has been given the tag-name *H.* aff. *maculatus* 'Canterbury'; however, we use *H. maculatus* here pending formal description of the species.

During ecological surveys carried out from 1967–1975, TW caught and individually marked 133 *H. maculatus* by toe-clipping. Geckos were captured in 25 pitfall traps spaced 5 m apart in a 20 × 20 m grid. The island was revisited in the summer of 1996–1997 and 16 of the original geckos were recaptured, at which time ten were estimated to be at least 36 years old (Bannock et al., *op. cit.*). In March 2005, ML visited the island and recaptured five geckos (two males, three females) originally marked by TW. When marked in 1967–1975 these geckos had snout-to-vent lengths that ranged from 47–73 mm. All except the largest individual could be assigned their approximate age (± 1 yr) by calibrating their SVL at time of first capture against the predicted SVL/age relationship growth curve generated by Bannock et al. (*op. cit.*). The estimated ages of these five 'old' geckos were 36, 36+, 37, 38, and a remarkable 42 years old! Interestingly, none of these geckos was recaptured by Bannock et al. (*op. cit.*). To our knowledge, our observation represents a new global record for longevity in a free-living gecko population. In addition, these geckos were still living within < 20 m of where they were marked more than 30 years earlier, thus implying significant site fidelity.

Our research adds to other observations on longevity and site

fidelity in New Zealand geckos. Such studies are not possible without a permanent marking system (e.g., toe clipping, PIT tagging) and long-term study involving different researchers (Hare and Cree 2005. New Zealand J. Ecol. 29:137–142). Despite the extreme longevity of New Zealand geckos, more than 80% are considered threatened or have a 'Data deficient' ranking due to a scarcity of records (36/43 or 83% of species; Hitchmough and Bull [compilers], in press.Threatened Species Occasional Publication, Department of Conservation, Wellington, New Zealand). The vulnerability of New Zealand geckos to introduced predators and habitat loss, coupled with their low annual reproductive output (≤ 2 offspring/female/yr; Cree, *op. cit.*) limit their ability to persist in human-altered landscapes, and highlight the pressing need for on-going and effective conservation management.

We thank the Department of Conservation for financial and logistic support. Anita Spencer and Jane Sedgeley provided assistance with field work.

Submitted by **MARIEKE LETTINK,** Department of Zoology, University of Otago, P.O. Box 56, Dunedin, New Zealand (e-mail marieke_kakariki@clear.net.nz); and **TONY WHITAKER**, 270 Thorpe-Orinoco Rd, R.D. 1, Motueka, New Zealand (e-mail: whitaker@ts.co.nz).

KENTROPYX STRIATA (Striped Kentropyx). **JUVENILE PREDATION**. *Kentropyx striata* is a common lizard in northern Brazil (Ávila-Pires 1995. Lizards of Brazilian Amazonian (Reptilia: Squamata). Zoologische Verhandelinger 299:1–706). Few predators of *K. striata* have been identified (Ávila-Pires, *op. cit.*). Here I describe an observation of Great Kiskadee (*Pitangus sulphuratus*) predation on a juvenile *K. striata* from northern Brazil. At 1150 h on 25 September 2001, I observed a juvenile (ca. 10 cm SVL) *K. striata* running in the backyard of a house in the village of Alter do Chão near the Tapajós River, Santarém, Pará State (2°30'S, 54°57'W, datum: WGS 84; elevation 50 m). Patches of savannah within Amazon forest vegetation characterized this region. A *P. sulphuratus* made an initial unsuccessful attempt to catch the lizard as it ran; it escaped into a pile of bricks. However, the bird caught the lizard on a second pass after pausing on a branch near the lizard's refuge for ca. 30 sec. After the capture, the *P. sulphuratus* carried the *K. striata* to a nearby tree and beat the lizard's head several times on the branch. Using its beak, the bird grabbed the lizard by the head and swallowed it head first. The entire predation episode took 3 minutes.

This observation reveals that small lizards can be vulnerable to smaller predatory birds, like this tyrannid flycatcher. *Pitangus sulphuratus*, a species broadly distributed in Brazil (Sick 1997. Ornitologia Brasileira, Nova Fronteira, Rio de Janeiro, Brazil. 912 pp.), can prey on a variety of animals, such as bats, fish, arthropods, amphibians, and reptiles (Sick, *op cit.*; Argel-de-Oliveira et al. 1998. Rev. Brasil. Zool. 15:1103–1109). This note represents the first record of *P. sulphuratus* predation on juvenile *K. striata*.

LEIOCEPHALUS CARINATUS ARMOURI (Northern Curlytail Lizard). **PREDATION.** *Leiocephalus carinatus armouri* is a well-established exotic species in Florida (Meshaka et al. 2004. The exotic amphibians and reptiles of Florida, Krieger Publishing Company, Malabar, Florida. 155 pp.; Meshaka et al., *in press*, Southeastern Nat. 4); however, few vertebrate predators of this species have been documented within its introduced range (e.g., Smith and Engeman 2003. Herpetol. Rev. 34:245–246; Smith and Engeman 2004a. Herpetol. Rev. 35:169–170; Smith and Engeman 2004b. Florida Field Nat. 32:107–113). To date, only one avian predator of *L. c. armouri*, the Little Blue Heron (*Egretta caerulea*), has been recorded in Florida (Smith and Engeman 2004a, *op. cit.*). Here, we augment the sparse information on avian predators of *L. c. armouri* in Florida with the observation of the probable predation of a juvenile *L. c. armouri* by a Northern Mockingbird (*Mimus polyglottos*).

At 1040 h on 30 April 2005, a clear sunny day (air temperature ca. 25°C), HTS observed an adult Northern Mockingbird perched atop fence-line shrubbery with a small lizard in its bill at the Woolbright Road colony site of *L. c. armouri* located in Boynton Beach (see Smith and Engeman 2003, 2004b, *op. cit.* for site descriptions). Closer examination revealed it to be a juvenile *L. c. armouri* (SVL ca. 5 cm). The lizard, being held sideways by its neck, was completely limp (including tail and limbs), and seemed dead. The lizard remained limp during the 20–30 sec observation period, after which the mockingbird flew out of view with its prey over an adjacent building rooftop. The pliant appearance of the *L. c. armouri* suggested to us that it was taken recently rather than scavenged.

Mockingbirds are generalist omnivores and have been reported to prey on *Anolis* lizards (Derrickson and Breitwisch 1992. *In* Poole et al. [eds.], The Birds of North America, Species Account No. 7, Northern Mockingbird, American Ornithologists' Union, Washington, D.C. and the Academy of Natural Sciences, Philadelphia, Pennsylvania. 26 pp.), and a Rough Earth Snake (*Virginia striatula*) (Sorrell 2004. Herpetol. Rev. 35:75–76).

MESHAKA, JR.**, The State Museum of Pennsylvania, 300 North Street, Harrisburg, Pennsylvania 17120-0024, USA.

MICROLOPHUS ATACAMENSIS (Atacama Desert Runner). **PREDATION**. Interspecific predation, like that between lizards and snakes in the Chilean Atacama desert (Labra and Niemeyer 2004. Ethology 110:649–662), is well documented in reptiles (e.g., Jackson et al. 2004. Zoology 107:191–200). *Microlophus atacamensis*, a lizard endemic to the coastal zones of northern Chile (Donoso-Barros 1966. Reptiles de Chile. Ediciones de la

Universidad de Chile, Santiago, Chile. 458 pp.), feeds on marine (crustaceans and green algae) and terrestrial (isopods, coleopterans, dipterans) prey (Ortiz 1980. Actas I Reunión Iberoamericana Zool. Vert., La Rábida, pp. 355–377). No studies have reported predation on *M. atacamensis,* implying that this species is a top predator (Fariña et al. 2003. Ecol. Appl. 13:1533–1552). Nonetheless, here we describe predation on *M. atacamensis* by *Philodryas chamissonis* (Long-tailed Snake, Chilean Green Racer), a diurnal hunter whose diet consists of anurans, passeriform birds, rodents, lagomorphs, and in particular, lizards of the genus *Liolaemus* (Greene and Jaksic 1992. Rev. Chil. Hist. Nat. 65:485–493).

During diurnal sampling for *M. atacamensis* at 1530 h on 10 July 2005, we encountered a male *Philodryas chamissonis* (667 mm SVL, 105.6 g, 12.8 mm head width) feeding on an adult male *M. atacamensis* (93.5 mm SVL, 89.5 g, 22.7 mm head width). The observation was made in a coastal zone at Arrayán, La Serena, Coquimbo's Province, Chile (29°41'S, 71°19'W, datum: WGS84; elev. 8 m). The habitat corresponds to an arid Mediterranean biome with thorny shrubs (di Castri 1968. *In* Delamare and Rapoport [eds.], Biologie de l'Amérique Austral, pp.7–52. Edition du Centre National de la Recherche Scientifique, Paris), including *Nolana lycioides* (Nolanaceae) and *Heliotropium stenophyllum* (Boraginaceae) as dominant species. When first encountered, the lizard was being ingested by the head, with its hind limbs and tail still exposed. Upon capturing the snake, the lizard was released.

This is the first record of predation on *M. atacamensis* and indicates that this species might not always be a top predator in the trophic web of the northern Chilean coast. Additional observations of this interaction will be required to understand its frequency and relevance to *M. atacamensis* population dynamics.

The snake (SSUC 7233) and lizard (SSUC 7234) were deposited in the collection Prof. Patricio Sánchez Reyes, Pontificia Universidad Católica de Chile. We thank María Victoria Reyna for field assistance and Fondecyt 1040783 for financial support to JMF.

NOROPS HUMILIS (Ground Anole). **KLEPTOPARASITISM.** Kleptoparasitism, a behavior in which a resource (frequently prey) is stolen from a potential competitor, has been repeatedly documented in birds, fish, mammals, and varied invertebrates, but to my knowledge, only two reports exist of kleptoparasitism among non-avian reptiles (Cooper and Perez-Mellado 2003. Amphibia-Reptilia 24:219–224; Whiting and Greef 1997. Copeia 1997:811–818). Here I augment the sparse data on kleptoparasitism in non-avian reptiles with two observations involving a common leaf-litter anole, *Norops humilis*, in northeastern Costa Rica.

Observations were made at the La Selva Biological Station (10°25'N, 84°00'W, datum WGS84; elev. ~40 m). This site is a 1600-ha primary evergreen wet forest reserve dominated by lowland closed canopy forest with relatively limited seasonality in precipitation (Sanford et al. 1994. *In* McDade et al. [eds.], La Selva: Ecology and Natural History of a Neotropical Rain Forest, pp. 18–33. University of Chicago Press, Chicago. 486 pp.). At ca. 1130 h on 18 July 2003, I observed an adult *Norops humilis* (~ 35 mm SVL) in leaf litter along a trail in primary forest. An unidentified ant (~ 10 mm long) was walking across the leaf litter carrying a lycosid spider (~10 mm SVL). The spider was immobile, presumably having been incapacitated by the ant. The lizard approached the ant and snatched the spider from the ant's grasp and retreated a short distance (~ 20 cm) where it consumed the spider. The ant made no attempt to reclaim its lost prey.

At 0857 h on 17 July 2005, I observed another adult *Norops humilis* (~30 mm SVL) in leaf litter along a trail in secondary forest. An unidentified myrmicine ant (~10 mm long) was walking slowly through leaf litter carrying a small bee (~10 mm long). The lizard approached the ant and snapped at the bee, seized it from the ant, and retreated ca. 20 cm to consume the bee, disregarding the ant. Again, the ant made no attempt to reclaim its prey.

My casual observations suggest that kleptoparasitism may be frequent in *N. humilis*. It was impossible to determine whether or not these lizards actually recognized the presence of the ants, so it is unclear whether this is a unique foraging strategy opportunistically employed by the lizards or if the lizards are simply responding to the behavioral stimuli for prey capture (movement of a small spider or bee across the leaf litter) regardless of the presence of the ants. To my knowledge, this is the first report of any reptile stealing prey from another species; these observations also suggest that opportunities may exist to investigate interspecific interference competition between markedly different organisms.

Submitted by **STEVEN M. WHITFIELD,** Florida International University, Department of Biological Sciences, UP Campus, OE 167, Miami, Florida 33199, USA; e-mail: steven.whitfield@fiu.edu.

PAROEDURA STUMPFFI (Madagascar Ground Gecko). **PREDATION.** *Zonosaurus madagascariensis* is widely distributed in Madagascar (Raselimanana 2003. *In* Goodman and Benstead [eds.], The Natural History of Madagascar, pp. 978–983. Univ. of Chicago Press, Chicago, Illinois). It occurs in dense primary forests on the east coast as well as deforested and cultivated areas on the west coast (Raxworthy 1988. Biol. Conserv. 43:181–211; Glaw and Vences 1997. A Field Guide to the Amphibians and Reptiles of Madagascar. 2nd edition. M. Vences & F. Glaw Verlags GbR, Köln. 480 pp.; Raselimanana, *op. cit.*). All species of *Zonosaurus* are diurnal and forage generally on the ground, although some climb trees (Raselimanana, *op. cit.*; Glaw and Vences, *op. cit.*). Their diet includes mostly insects and fruits (Raselimanana, *op. cit.*). Some *Zonosaurus* are reported to consume small vertebrates (Raselimanana, *op. cit.*), but the genus *Pareodura* has not been reported as prey. Hence, I add to what little is known about the feeding habits of *Zonosaurus* in nature with an observation of predation on *P. stumpffi* by *Z. madagascariensis*.

This observation was made during a field trip to Madagascar in September 2004 on Nosy Komba, a small (2200 ha) island off the northwest coast (48°19'–48°21'S, 13°26'–13°28'E; Andreone et al.

2003. J. Nat. Hist. 37:2119–2149). I became aware of the animals because something was moving rapidly and rustling in the litter near a small limestone formation. A subadult (ca. 10 cm SVL) *Z. madagascariensis* was hunting a small (ca. 4 cm SVL) gecko. The gecko displayed the conspicuous coloration of juvenile *Paroedura stumpffi*: several white cross bands on a dark dorsal ground color. After a few seconds of pursuit, the gecko threw off its tail, but the *Zonosaurus* caught it just behind his head. The *Zonosaurus* slipped between pieces of limestone, where it presumably swallowed the gecko. After several minutes, the *Zonosaurus* emerged again and grabbed the tail of the gecko, which was still moving, and ate it.

In contrast to other Malagasy geckos, some species of *Paroedura* are exclusively terrestrial (e.g., *Paroedura pictus*), and juveniles of most species differ in coloration from adults (Glaw and Vences, *op. cit.*; Bauer 2003. *In* Goodman and Benstead [eds.], The Natural History of Madagascar, pp. 973–977. Univ. Chicago Press, Chicago, Illinois). As *Paroedura stumpffi* frequently utilizes forest-floor habitats on the north and northwest coast of Madagascar, including the nearby island Nosy Be (Andreone et al., *op. cit.*; Glaw and Vences, *op. cit.*; Liebel et al. 2004. Draco 5:28–39) and the Comores (Liebel et al., *op. cit.*), significant opportunity exists for it to serve as prey for the frequently terrestrial foraging *Z. madagascariensis*. This represents the first report of *Pareodura* predation by *Zonosaurus*.

PHELSUMA MADAGASCARIENSIS GRANDIS (Madagascar Giant Day Gecko). **NECTARIVORY; POTENTIAL POLLINATION**. Some palms (Arecales: Arecaceae) are mainly insect-pollinated (though some may be wind-pollinated), and both pollen and nectar are rewards to their pollinators (Henderson 1986. Bot. Rev. 52:221–259). Day geckos (*Phelsuma* spp.) are reported to be important pollinators by providing plant outcrossings in their native range (Nyhagen et al. 2001. J. Trop. Ecol. 17:755–761) and in their introduced range on Hawaii (Calviño-Cancela 2005. Herpetol. Rev. 36:182–183). Herein, we report nectar consumption and the potential for pollination of non-native coconut palms (*Cocos nucifera*) by non-native *Phelsuma madagascariensis grandis* in the lower Florida Keys.

Phelsuma m. grandis is native to northern Madagascar (Henkel and Schmidt 2000. Amphibians and Reptiles of Madagascar and the Mascarene, Seychelles, and the Comoro Islands. Krieger Publishing Company, Malabar, Florida, 319 pp.) and has been introduced onto five islands in the Florida Keys (Krysko et al. 2003. Florida Sci. 66:222–225; Krysko and Sheehy 2005. Carib. J. Sci. 41:169–172). On 6 July 2003 at 1000 h, we observed an adult (ca. 190 mm total length [TL]) *P. m. grandis* that had climbed onto the flowering spikes of a *Cocos nucifera* on Little Torch Key (24°40.39'N, 81°23.262'W, datum: WGS84; elev. < 1 m). This gecko licked the nectar from male flowers for about 20 min before climbing to a more secluded position on the tree. At 0900 h on 9 July 2003, we observed 3 adults (ca. 200–250 mm TL) of both genders exhibiting this same foraging behavior for ca. 30 min on another *C. nucifera*. These geckos were also observed snapping at hymenopterans as the insects approached flowers. At 0910 h that same day, we observed a neonate (ca. 70 mm TL) *P. m. grandis* licking nectar from male flowers on a nearby *C. nucifera*. This small gecko allowed us to approach it within ca. 25 cm for photography. Since these observations were made, we have noted this foraging behavior on at least 5 occasions suggesting that the behavior is not a rare phenomenon.

Cocos nucifera is normally allogamous, but autogamy may occur (Patel 1938. The Coconut. Government Press, Madras, India; Ohler [ed.] 1999. Modern Coconut Management, Palm Cultivation and Products. Available online: http://ecoport.org/ep?SearchType=earticleView&earticleId=127&page=-2; Meléndez-Ramírez et al. 2004. Agric. For. Entomol. 6:155–163). Climbing on flowers and drinking nectar followed by contact of both stamens and stigmas in the same palm could result in autogamy. If geckos were to simply climb onto a nearby palm, outcrossings might occur as they do in other areas *Phelsuma m. grandis* occurs.

We thank A. P. Borgia, S. W. Morey, K. K. Nichols, and B. J. Camposano for assistance in the field; F. and S. Morey, and A.P. Borgia for accommodations; Walter S. Judd for plant ID and botanical information; Max A. Nickerson for comments on this note.

PHYLLODACTYLUS VENTRALIS (Venezuelan Leaf-toed Gecko). **ECOLOGY; PREDATION.** *Phyllodactylus ventralis* is the only member of its genus in northeastern Colombia and the northern Venezuelan mainland, where it inhabits mostly dry thorn forests and savannahs (Dixon and Huey 1970. Contr. Sci. Los Angeles Co. Mus. Nat. Hist. 192:1–78; Rivas and Barrio-Amorós 2005. Herpetol. Rev. 36: 205–209). Although this is the most common of the three *Phyllodactylus* species in Venezuela, almost nothing is known of its natural history. Ruthven (1922. Misc. Pub. Mus. Zool. Univ. Michigan 8:5–69) and Mechler (1968. Rev. Suisse Zool. 75:305–371) provided a few ecological data on Colombian populations, but the only data for Venezuelan populations are the brief comments in Roze (1964. Mem. Soc. Cienc. Nat. La Salle 69:209–241). Hence, here we report on *P. ventralis* retreat sites from the arid region of north-central Venezuela, on the species that share these microhabitats, and on a snake predator.

Our observations took place at a campground on Camatagua Reservoir in the northern part of the State of Aragua, Venezuela (09°49'3.36"N, 66°46'41.28"W, datum: WGS84; elev. 230 m) between 0900 and 1730 h on 16 May 2001, a hot (> 30°C), dry day with a constant slight breeze. Local vegetation consists of dry thorn scrub. The few buildings in the campground consisted of open picnic shelters with wooden roofs. Numerous corrugated metal panels, other trash, and rocks were on the ground beneath the shelters. Four *P. ventralis* were found under rocks, both those shaded by the shelters and those exposed to direct sunlight. Another 3 *P. ventralis* were observed beneath metal panels and other trash. The

wooden roofs and columns of the shelters offered many crevices and potential retreat sites; despite careful inspection, we found no geckos there. All *P. ventralis* were found under terrestrial cover on the ground during the day. Overturned rocks revealed up to three individuals sharing the same retreat site. Under one of these, two adults and a juvenile were found, showing no obvious signs of intraspecific antagonistic behavior. We also found scorpions (*Rhopaulurus laticauda*) sheltering under rocks with many of the geckos; a mouse (probably *Mus musculus*) was found under each of two metal panels with *P. ventralis*. The harsh, arid climate at Camatagua may induce nocturnal animals to share terrestrial retreat sites.

Analysis of the stomach contents of a specimen of the colubrid snake *Leptodeira annulata ashmeadii* deposited in the herpetological collection of the Museo de Historia Natural La Salle, Caracas (MHNLS), revealed a *P. ventralis*. The snake (MHNLS 9818), a juvenile (295 mm SVL), was collected at the Urbanizacion El Tejar, Puerto Piritu, in the northern portion of the State of Anzoategui. Despite its small size, the snake had an adult female *P. ventralis* (73 mm SVL) with a recently broken tail in its gut. Judging from its position in the snake, the lizard was eaten head-first. Duellman (1958. Bull. Amer. Mus. Nat. Hist. 114:1–152) reported mostly frogs and toads from the stomachs *L. annulata*, but he also found one *Gonatodes vittatus*, a smaller diurnal species. Lack of experience often exhibited by young snakes may explain the presence of such a large prey item in this juvenile *L. annulata*. To our knowledge, this is the first record of predation on *P. ventralis* and the second on lizards by the snake *L. annulata*. We thank Aaron Bauer (Villanova University) for his valuable comments and corrections to a preliminary version of this note.

SCELOPORUS COUCHI (Couch's Spiny Lizard). **SAUROPHAGY**. *Sceloporus couchi*, one of the least known phrynosomatid lizards in México, is restricted to the central-western portion of the state of Nuevo León, and the central eastern portion of the state of Coahuila (Köhler and Heimes 2002. Stachelleguane, Herpeton, Offenbach, Bundesrepublik Deutschland. 174 pp.; Smith 1939. Zool. Ser. Field Mus. Nat.Hist. 26:1–397). Here, we provide a record of saurophagy for *S. couchi* from Nuevo León, México.

At 1030 h on 28 May 2005, while conducting a vertebrate inventory in the municipalities of Dr. Gonzalez, Higueras, and Cerralvo, in the Sierra Picachos (25°58'08"N, 99°53'32"W, datum: NAD27; elev. 794 m), we collected an active adult (58.8 mm SVL, 94.0 mm tail, 5 g) male *S. couchi* male (air temperature 27°C) in a small canyon named Potrero Grande. It was found in an open dry river channel with walls of conglomerate; *Cordia boisieri*, *Pithecellobium pallens*, *Hellieta parvifolia*, *Prosopis glandulosa*, and *Aloysia macrostachya* dominated the vegetation along the channel. When first observed, the lizard was eating a neonate *S. poinsetti poinsetti* (29.8 mm SVL, 1.2 mm tail) with a broken tail. Other sympatric phynosomatid lizards observed in the area included *S. grammicus disparilis and S. parvus parvus*. This is the first observation of saurophagy in *S. couchi*.

The lizard (UANL 6772) was deposited in the herpetological collection of Universidad Autonoma de Nuevo Leon, Facultad de Ciencias Biologicas.

CONTRERAS-BALDERAS, GAMALIEL CASTAÑEDA**, and **CRISTINA DE LA PEÑA GARCIA**, Universidad Autónoma de Nuevo León, Facultad de Ciencias Biológicas, Laboratorio de Herpetología, Apartado, Postal - 513, San Nicolás de los Garza, Nuevo León, C.P. 66450, México; e-mail: (DL) dvlazcano@hotmail.com.

SCELOPORUS CYANOGENYS (Blue Spiny Lizard). **PREDATION.** The few studies on the biology of *Sceloporus cyanogenys* address reproduction (Kennedy 1960. Southwest. Nat. 5:44–45), general behavior (Greenberg 1977. J. Herpetol. 11:177–195), taxonomy and distribution (Wiens and Reeder 1997. Herpetol. Monogr. 11:1–101), and mite infestation (García-de la Peña et al. 2005. Bull. Chicago Herp. Soc. 40:52–53). Here we add an observation of predation on this lizard.

During a visit to Parque Ecológico Chipinque (municipios of Monterrey and San Pedro Garza Garcia, Nuevo León, México), in an area known as El Estacionamiento (25°37'11.747"N, 100°21'35.171"W, datum: NAD27; elev. 1091 m) on 16 June 2004, we found a small female (311 mm total length, 7.1 g) Southwestern Rat Snake (*Pantherophis emoryi*) that had ingested two-thirds of a 58 mm SVL (4.7 g) female *Sceloporus cyanogenys*. The snake was found DOR, presumably killed by a vehicle before it could swallow the entire lizard. This demonstrates snake vulnerability during ingestion on roadways near human development, and adds *P. emoryi* to the *S. cyanogenys* predator set.

Both reptiles were photographed and deposited (UANL 6349ab) in the herpetological collection of Universidad Autonoma de Nuevo León, Facultad de Ciencias Biologicas.

Submitted by **GAMALIEL CASTAÑEDA, DAVID LAZCANO, CRISTINA GARCÍA-DE LA PEÑA**, and **JORGE A. CONTRERAS-LOZANO**, Universidad Autónoma de Nuevo León, Facultad de Ciencias Biológicas, Laboratorio de Herpetología, Apartado, Postal - 513, San Nicolás de los Garza, Nuevo León, C.P. 66450, México; e-mail: (DL) dvlazcano@hotmail.com.

SCELOPORUS VIRGATUS (Striped Plateau Lizard). **CLUTCH SIZE**. Mean clutch size in *Sceloporus virgatus* from the Chiricahua Mountains of southeastern Arizona ranges from 7.6 to 10.15 (Abell 1999: J. Herpetol. 33:173–180; Smith et al. 1995. Herpetologica 51:342–349; Vinegar 1975. Ecology 56:172–182). However, virtually nothing is known of clutch size in this species outside of the Chiricahua Mountains.

As part of a study on the herpetofauna of Chihuahua and Sonora (Lemos-Espinal et al. 2004: Introducción a los Anfibios y Reptiles del Estado de Chihuahua, CONABIO. 128 pp.), we collected

specimens of *S. virgatus* from Puerto de San Luis, Sierra San Luis, Sonora, México (31°19'12.0"N, 108°45'42.0"W, datum: WGS84; elev. 1417 m). One of these individuals was a gravid female (53 mm SVL) with 4 shelled eggs. The observed clutch size of 4 is less than the 6.77 predicted for a similar-sized female from the Chiricahua Mountains using the regression of clutch size on SVL in Smith et al. (*op. cit.*). This difference, although based on one clutch, implies that significant interpopulation variation in clutch size may exist in *S. virgatus*.

SERPENTES

AGKISTRODON PISCIVORUS LEUCOSTOMA (Western Cottonmouth). **DIET**. Cottonmouths are opportunistic predators and scavengers that consume a variety of vertebrate prey (Gloyd and Conant 1990. Snakes of the *Agkistrodon* Complex: A Monographic Review. SSAR, Oxford, Ohio. 614 pp, and references therein). Watersnakes (*Nerodia* spp.) are considered a common component of the cottonmouth diet, but few studies have reported which species of *Nerodia* are consumed (Burkett 1966. Univ. Kansas Publ. Mus. Nat. Hist. 17:435–491; Gloyd and Conant, *op. cit.*). Here, we report *Agkistrodon piscivorus leucostoma* attempting to prey upon *Nerodia erythrogaster flavigaster*.

At ca. 1430 h on 3 August 2005 we encountered an adult *A. p. leucostoma* in a dry creek bed (Goose Prairie Creek) in the Caddo Lake National Wildlife Refuge (CLNWR), Harrison County, Texas, USA. Directly adjacent to the cottonmouth was a dead adult male *N. e. flavigaster* (576 mm SVL, 765 cm TL; 139 g). We observed two puncture wounds surrounded by a moist sheen on the dorsum of the *N. e. flavigaster*, ca. 300 mm posterior of the rostrum. *Agkistrodon piscivorus* are known to eject venom from the fangs when releasing prey following envenomation (Kardong 1975. J. Herpetol. 9:169–175) and we speculate that the moist sheen around the bite mark on the watersnake was fresh cottonmouth venom. Shortly following our arrival, the *A. p. leucostoma* crawled out of the creek bed and into adjacent bottomland hardwood forest. We collected the *N. e. flavigaster* for further examination, and it was later deposited in the Campbell Museum, Clemson University, Clemson, South Carolina (CUSC 2291).

Although *A. piscivorus* are known to feed on carrion, including dead watersnakes (Berna and Gibbons 1991. Herpetol. Rev. 22:130–131; Hamel 1996. Herpetol. Rev. 27:143), our observations suggest envenomation of a live watersnake with the intent of consumption. The cottonmouth might have envenomated and held the watersnake at the location at which we encountered the two snakes, or it may have envenomated it elsewhere and trailed it to this location (Kardong 1982. Copeia 1982:337–343; Chiszar et al. 1986. J. Herpetol. 20:269–272). To our knowledge, this is the first account of *Agkistrodon piscivorus leucostoma* envenomating *Nerodia erythrogaster flavigaster*. Although Collins and Carpenter (1970. Proc. Oklahoma Acad. Sci. 49:15–18) reported finding two "yellow-bellied water snakes" in the stomach of a Western Cottonmouth, the scientific name they provided (*Natrix erythrogaster transversa*) and the location from which the cottonmouth was collected suggest these snakes were most likely Blotched Watersnakes (*N. e. transversa*) rather than Yellow-bellied Watersnakes (*N. e. flavigaster*).

ALSOPHIS PORTORICENSIS ANEGADAE (NCN). **AQUATIC ACTIVITY**. West Indian racers in the genus *Alsophis* are generally characterized as diurnal, primarily terrestrial, actively foraging snakes. Many of the islands on which they live do not have permanent bodies of fresh water and few references address aquatic activity.

In the course of a multi-year study of population structure of *A. portoricensis anegadae* on Guana Island (British Virgin Islands), we recorded four instances of aquatic activity. In October 2003, an adult snake escaped capture by entering and swimming across an intermittent pool of water several meters wide and about 20 cm deep. Three additional observations were made during an unusually pluvial year (2005). On 6 October, an individual (579 mm SVL) attempted to escape capture by diving into a temporary pool near the base of Quail Dove Ghut. Once submerged, it remained motionless with its anterior body adpressed against accumulated debris about 30 cm deep until disturbed by the collector. On 8 October, a female (653 mm SVL) was found near North Beach swimming in a large pool covering a flooded dirt track and adjacent forest. On 9 October, another female (570 mm SVL) was found in the southeastern lowlands resting at the edge of a large puddle with over half of its body in the water, suggesting that it had just crossed the water. Members of the staff residing on the island also reported sporadic observations of snakes swimming in the sea (T. Peliwan, pers. comm.). All but one sighting occurred in shallow water within 20 m of shore, but one snake was reportedly seen swimming toward a nearby island.

We have found no previous records of aquatic behavior in this species, but some exist for congeners (Schwartz and Henderson. 1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. Univ. Florida Press, Gainesville. xvi + 720 pp.). Although anecdotal, our observations suggest that *A. p. anegadae* is at least opportunistically aquatic, presumably in

much the same fashion as it is facultatively arboreal. Moreover, ocean swimming might explain how some snakes disperse from one Caribbean island to another.

We thank Henry and Gloria Jarecki and the Falconwood Foundation for the opportunity to conduct research on Guana Island.

FIG. 1. Juvenile *Bothrops jararaca* capturing a *Hypsiboas bischoffi*.

BOTHROPS JARARACA (Jararaca). **PREY**. *Bothrops jararaca* is a terrestrial, slender, and medium-sized viperid snake widespread in southeastern Brazil (Campbell and Lamar 2004. The Venomous Reptiles of the Western Hemisphere. Cornell University Press, Ithaca, New York. 870 pp.). This species preys mainly on small vertebrates and exhibits an ontogenetic shift in diet: juveniles feed mostly on frogs, commonly attracted by caudal luring, whereas rodents are the main food of adults (Sazima 1992. *In* Campbell and Brodie Jr. [eds.], Biology of the Pitvipers, pp. 199–216. Selva, Tyler, Texas; Martins et al. 2002. *In* Schuett et al. [eds.], Biology of the Vipers, pp. 1–22. Eagle Mountain Publishing, Utah).

Here we present data about previously undocumented prey taxa and habitat use of juvenile *B. jararaca* from Parque Estadual Carlos Botelho, municipalities of Sete Barras and São Miguel Arcanjo, State of São Paulo, southeastern Brazil, in an area of Tropical Atlantic Rain Forest.

On 11 December 1999 (2200 h; 20°C), we observed a juvenile *B. jararaca* (ca. 420 mm SVL) preying on a tree frog, *Hypsiboas bischoffi* (ca. 50 mm SVL) at the edge of a permanent pond. The snake was coiled in the leaf litter, immobile, in ambush posture. Caudal luring was not observed. As the frog jumped toward the snake, the snake struck quickly, seizing the frog until all movements ceased (Fig. 1). The snake then released the frog, inspected it, and began ingestion headfirst. The predation sequence lasted ca. 110 sec. After ingestion, the snake returned to its original position.

On 9 February 2002 (0005 h; 22°C) we encountered another juvenile *B. jararaca* (270 mm SVL) coiled in a tree branch at a height of ca. 50 cm. The snake was apparently inactive. Following manipulation, the snake regurgitated a leptodactylid frog, *Eleutherodactylus binotatus*, with its anterior region partially digested.

Between 2000 and 2002 we observed 10 active juvenile *B. jararaca* in the study area: one were found during the day, two in the evening, and seven at night. Three were observed in leaf litter; seven were encountered in vegetation 30–200 cm above ground (mean = 123.6 cm, SD = 62.7 cm). Our data differ from those reported by Hartmann et al. (2003. Phyllomedusa 2:35–41) in which most juvenile *B. jararaca* observed along streams in one Atlantic Forest area were found active during the day, foraging on diurnal frogs at ground level. Taken together, these observations suggest that juvenile *B. jararaca* are most active at the same time of locally abundant prey.

We are grateful to Instituto Florestal de São Paulo for logistic support, to Conselho Nacional de Desenvolvimento Científico e Tecnológico for undergraduate fellowship to RAM, and Fundo FAP-PUCSP for a research grant to LMC. We thank IBAMA for the collection license (number 612/99). This study was partially supported by the Fundação de Amparo à Pesquisa do Estado de São Paulo, Programa Biota Fapesp (grant No. 01/1334-3).

CORALLUS ANNULATUS (Annulated Boa). **OVOPHAGY.** *Corallus annulatus* is a boid whose ecology and behavior are poorly known. Its distributional range extends from Guatemala south to Colombia (Henderson et al. 2001. Stud. Neotrop. Fauna Environ. 36:39–47). In Costa Rica, this primarily arboreal species inhabits the Caribbean versant at elevations up to 650 m, where it generally occupies the upper parts of trees; it has been found at heights from a few meters up to 40 m (Solórzano 2004. Serpientes de Costa Rica/Snakes of Costa Rica. INBio, Santo Domingo de Heredia, Costa Rica. 792 pp.).

Three adult *Corallus annulatus* (1 male, ca. 1 m TL; 2 females, each ca. 1.5 m TL) collected at Guayacán de Siquierres, Limón Province, Costa Rica, were held in captivity at Parque Reptilandia (SW San José Province) for over one year. On 1 November, the male was introduced into the females' enclosure. Within two days the male copulated with both females, and sexual activity continued until 13 November.

On 19 July, prior to 0600 h, the first female gave birth to nine offspring and passed at least five undeveloped ova (= slugs). When the female was first observed, she was eating one of the slugs and apparently had ingested at least two others (Fig. 1). On 4 August,

FIG. 1. A female *Corallus annulatus* eating an undeveloped ovum after parturition.

from late morning to early afternoon, the second female gave birth to 12 offspring. This female also was observed to eat the undeveloped ova.

Captive observations on the post-parturient behavior of certain species of New World boids suggest protective advantages to adults and young after parturition. Females of *Corallus hortulanus*, *Epicrates maurus*, *E. fordii*, *E. s. striatus*, *E. s. strigilatus*, and *Eunectes murinus* have been reported to eat freshly passed undeveloped ova and/or living or dead young (Neill and Allen 1962. Quart. J. Florida Acad. Sci. 25:73–75; Hanlon 1964. Herpetologica 20:143–144; Boos 1976. AAZPA Newsletter 17[9]:13; Huff 1980. *In* J. B. Murphy and J. T. Collins [eds.], Reproductive Biology and Diseases of Captive Reptiles, pp. 125–134. SSAR Contrib. Herpetol. 1; Townson 1978. Brit. Herpetol. Soc. Newsl. 18:11–14; Groves 1980. Brit. J. Herpetol. 6:89–91; Miller 1983. Herpetol. Rev. 14:46–47). Neill and Allen (*op. cit.*) suggested that females might obtain physiologically and metabolically useful substances by ingesting their own birth debris. Groves (*op. cit.*) felt that this behavior might be influenced by captivity, and further suggested that living young are eaten because of poor development or a weakened condition and thus would not have survived. Further, Groves (*op. cit.*) proposed that because this behavior was reported only in species that produce their young in aquatic or terrestrial situations, where chances of predation are high, that it might relate to the protection of young and adults from potential predators by eliminating odors associated with the birth debris. Although Miller (*op. cit.*) reported a captive observation of ovophagy in the arboreal *Corallus hortulanus*, it is unknown whether in nature *C. hortulanus* gives birth to young in terrestrial or arboreal situations.

In view of the observations presented here and those in the literature, it appears that ovophagy is not uncommon in certain boids in captive situations. Because of the debilitated state of female boids after a lengthy gestation and parturition, we concur with Neil and Allen (*op. cit.*) that female snakes might obtain physiologically and metabolically useful substances by ingesting their birth debris. It remains unknown, however, whether in nature arboreal boids like *Corallus annulatus* and *C. hortulanus* give birth in arboreal or terrestrial situations, and thus the suggestions of Groves (*op. cit.*) remain inconclusive.

CORALLUS HORTULANUS (Amazon Treeboa). **DIET**. *Corallus hortulanus* is an arboreal, nocturnal, forest and forest-edged boid widely distributed in the Guianas and in the Amazon Basin (southern Colombia, southern Venezuela, Ecuador, Peru, Bolivia and Brazil) (Henderson 2002. Neotropical Treeboas: Natural History of the *Corallus hortulanus* Complex, Krieger Publ., Malabar, Florida. 197 pp.). Henderson (*loc. cit.*) summarized the feeding habits of *C. hortulanus* by indicating that the species is euryphagic, feeding on frogs, lizards, birds, bats, rodents and other small mammals.

In early October 2004, a large adult female *Corallus hortulanus* (150.7 cm total length) was killed by itinerant miners living at Menzie's Landing in Kaieteur National Park (05°10'23"N; 59°28'52"W), Guyana, preserved in formalin and donated to us. The snake was found in primary forest, in a tree along the Potaro River and had a remarkable swelling in its abdomen, which proved to be a just-fledged -Paradise Jacamar (*Galbula dea*, Galbulidae). The bird, swallowed headfirst, was partly digested but was still identifiable.

The Paradise Jacamar is a bird known to perch on low to high outer branches of forest-edge trees along water courses (de Schauensee and Phelps 1978. A Guide to the Birds of Venezuela, Princeton University Press, New Jersey. 424 pp.). This environmental setting is similar to the habitat of *C. hortulanus* in Kaieteur National Park.

This report is the first record of *C. hortulanus* eating *G. dea* and the first record of *C. hortulanus* feeding on a bird in the family Galbulidae.

In Kaieteur National Park, active *C. hortulanus* were commonly observed at the beginning of the night in trees along streams. In addition to the aforementioned specimen, two other adult specimens were collected as vouchers by us during our inventory of the park's herpetofauna. Both snakes were foraging in trees along streams around 2100 h, at heights of 2–6 m, and both had empty stomachs.

The *C. hortulanus* and the remnants of the *G. dea* are deposited under the same collection number (IRSNB 17049) in the herpetological collections of the Royal Belgian Institute of Natural Sciences, Brussels, Belgium.

We gratefully acknowledge the financial support of the Directorate General of Development Cooperation (Belgian Development Cooperation), and the National Science Foundation (NSF). We also thank the people of Menzie's Landing, Kaieteur National Park, Guyana, for preserving the snake and donating it to us. Permission to conduct the herpetofaunal surveys was granted by the Prime Minister of Guyana, Honorable Samuel Hinds, and S. Nokta and I. Nathoo of the Guyana National Parks Commission, with research and collection permit 180604 BR 011 issued by the Guyana Environmental Protection Agency.

CROTALUS BASILISCUS (Mexican West Coast Rattlesnake). **PREDATION.** Several species of snakes have been documented as predators of adult rattlesnakes (Klauber 1972. Rattlesnakes: Their Habits, Life Histories, and Influence on Mankind, 2 vols. 2nd ed. Univ. of California Press, Berkeley. 1533 pp.), although the extent of this phenomenon remains unknown. Radio-telemetry research suggests that predation of adult rattlesnakes by other snakes is infrequent, however the number of observations has significantly increased over the past decade with the onset of new technology used to study rattlesnakes. Herein we report on the predation of an adult *Crotalus basiliscus* by an adult Indigo Snake (*Drymarchon corais*).

On 15 August 2005, a large adult *Drymarchon corais* was observed resting along the banks of the Rio Cuchujaqui in southern Sonora, Mexico. The snake was ca. 1675 mm SVL, and was in the middle of ecdysis as its eyes were opaque. Upon being captured and photographed, the snake regurgitated the remains of an adult *Crotalus basiliscus* (ca. 1200 mm TL) with an incomplete rattle with 12 segments. To our knowledge, this observation represents the first published snake predator of *C. basiliscus*. Indigo Snakes are common along the rivers and arroyos in southern Sonora and are likely significant predators of snakes in these regions. Greene (1997. Snakes: The Evolution of Mystery in Nature. University of California Press, Berkeley, California. 196 pp.) provides accounts of Indigo Snakes consuming other large snake species, including rattlesnakes. Observations of predation by snakes on adult rattlesnakes remain infrequent, although with new technology and further research into the diets of large snakes, the number of similar observations might increase.

DRYMOLUBER DICHROUS (NCN). **OPHIOPHAGY.** A female *Thamnodynastes hypoconia* (SVL = 310 mm; TL = 144 mm) was found in stomach contents of a mature male *Drymoluber dichrous* (SVL = 768 mm; TL = 344 mm) collected in Municipality of Ilhéus, Bahia, Brazil (14º49'S; 39º02'W) (Museu Nacional, Rio de Janeiro; MNRJ 2195) on 5 March 1944. The direction of ingestion was anterior–posterior. Borges-Nojosa and Lima (2001. Bol. Mus. Nac. Zool. 468:1–5) noted that anurans (especially from the family Leptodactylidae) and lizards (Gekkonidae and Gymnophthalmidae) comprised the diet of *D. dichrous* examined from an Atlantic Forest population (Ceará, Brazil). Ophiophagy in *D. dichrous* was previously noted only from Amazonian populations (Cunha and Nascimento 1978. Publ. Avul. Mus. Par. Emílio Goeldi 31:1–218; Cunha et al. 1985. Publ. Avul. Mus. Par. Emílio Goeldi 40:10–92; Dixon and Soini 1986. The Reptiles of the Upper Amazon Basin, Iquitos Region, Peru. Milwaukee Publ. Mus., Milwaukee, Wisconsin), in which the colubrid genera *Oxybelis* and *Drymoluber* were reported as prey.

Species identifications were confirmed by Francisco L. Franco and Ronaldo Fernandes.

LAMPROPELTIS TRIANGULUM ELAPSOIDES (Scarlet Kingsnake). **OPHIOPHAGY**. *Lampropeltis triangulum elapsoides* is known to take a variety of prey items, including snakes: *Carphophis amoenus*, *Opheodrys vernalis*, *Storeria dekayi*, *Tantilla coronata*, *Thamnophis sirtalis*, and *Virginia striatula* (Williams 1988. Systematics and Natural History of the American Milk Snake, *Lampropeltis triangulam*. Milwaukee Public Museum. 176 pp.; Palmer and Braswell 1995. Reptiles of North Carolina. Univ. North Carolina Press. 412 pp.). Here I report a novel prey item for *L. t. elapsoides*.

On 19 March 2005 at 1603 h, I found a female *L. t. elapsoides* (351 mm SVL, 52 mm tail length, 18 g) under the loose bark of a fallen *Pinus palustris* (Longleaf Pine) in Forrest County, Mississippi, USA. Upon measuring the animal it regurgitated two juvenile *Diadophis punctatus* (124 and 142 mm SVL, 29 and 31 mm tail length, 2.0 and 3.0 g, respectively). The *L. t. elapsoides* was given a unique identification mark (Brown and Parker 1976. J. Herpetol. 10:247–249), and both the snake and the prey items were placed under the bark at the point of capture. On 20 March 2005 at 1700 h, I discovered the *L. t. elapsoides* in the exact same location with a slight bolus in its stomach and both *D. punctatus* were missing. Presumably, the snake re-ingested both prey.

LAMPROPELTIS ZONATA (California Mountain Kingsnake) **PREDATION**. On 26 September 1999, a dead *Lampropeltis getula* (188 g; CUMV catalog number pending) was found on Bear Creek Road ca. 3 km W of Summit Road in the Santa Cruz Mountains (Santa Cruz County, California, USA). In its stomach were the nearly complete remains of an adult *Lampropeltis zonata* (53 g; CUMV catalog number pending). The range of *L. getula* overlaps or lies adjacent to the range of *L. zonata* (Stebbins 1985. Western Field Guide to Reptiles and Amphibians. Houghton Mifflin, Bos-

FIG. 1. Adult *Diadophis punctatus* swallowing a juvenile *Lampropeltis zonata*, Tuolumne Co., California, USA.

ton, Massachusetts), though habitat associations may render these species largely segregated. Both species are known from the general vicinity of this observation (MVZ 32243, 47168, 50770, 209452). Although *L. getula* is larger and known for preying on other snakes, this is the first record of a predator-prey interaction between these species.

On 15 May 2005 at ca. 1330 h, in the Sierra Nevada (Tuolumne County, California, USA) a *Diadophis punctatus* was observed ingesting a juvenile *L. zonata*. When discovered, the *L. zonata* was approximately half consumed, motionless, and flaccid. The *L. zonata* and *D. punctatus* had a combined mass of 21.3 g. The *L. zonata* was similar in size to young of the previous year at this location (mean mass = 6.1 ± 0.7 g, range 4.8–7.2 g, N = 12). Extrapolating from this, we estimate the original mass of the *D. punctatus* at roughly 15 g. *Diadophis punctatus*, especially *D. p. regalis*, are known for preying on other snakes, although there is only a single record of ophiophagy for a Californian *D. punctatus*, involving the consumption of a *Thamnophis hammondii* (Goodman and Tate 1997. Herpetol. Rev. 28:90). Populations of these two species are often both sympatric and syntopic (Stebbins 1985, *op. cit.*; pers. obs.), suggesting a potential for frequent predator-prey interactions.

Submitted by **RICHARD STAUB**, 223 Baja Avenue, Davis, California 95616, USA (e-mail: rickstaub@bionovo.com); **MITCHELL MULKS,** University of California, Santa Cruz, Earth and Marine Sciences D450, 1156 High Street, Santa Cruz, California 95064, USA; **GEROLD MERKER**, 30 Rancho Del Sol, Camino, California 95667, USA.

LATICAUDA SAINTGIRONSI (New Caledonian Yellow-lipped Sea Krait). **PREDATION.** *Laticauda saintgironsi* is a newly described species of sea krait that is endemic to the New Caledonian region (Heatwole et al. 2005. Herpetol. Monogr. 19:1–136). It occurs in high density in waters surrounding southern New Caledonia and spends much of its time on land, chiefly on small islets (Ineich and Laboute 2002. Sea Snakes of New Caledonia. IRD Éditions, Paris. 302 pp.; Saint Girons 1964. Terre et Vie 1964:185–214). Its confirmed predators in New Caledonia include Ospreys (*Pandion haliaetus*; Leach 1928. Emu 28:20–42) and Reef Herons (*Egretta sacra*; Bauer and DeVaney 1987. Proceedings of the 4th Ordinary General Meeting of the Societas Europaea Herpetologica. Catholic University of Nijmegen, Nijmegen, pp. 43–48) as well as sharks and other large fishes (Saint Girons 1964, *op. cit.*; Rancurel and Intès 1982. Tethys 10:195–199). At 1230 h on 1 July 2004, a ghost crab (*Ocypode* sp., ca. 80 mm carapace width) was observed actively feeding on a dead juvenile *L. saintgironsi* (ca. 650 mm TL) on the northern sandy shore of Moro, a small islet located ca. 2 km off of the west coast of the Isle of Pines, New Caledonia (22°39'06"S, 167°23'37"E). There was a large laceration on the lateral side of the snake's tail and another behind the head, where the crab was feeding. Although it was not possible to determine whether the snake had been killed or merely scavenged by the crab, predation by a portunid crab (Guinea 1986. Aspects of the Biology and Toxicology of the Common Fijian Sea Snake *Laticauda colubrina* (Schneider). Unpubl. Master's thesis, University of the South Pacific, Suva, Fiji. v + 206 pp.) and injuries consistent with crab predation have been observed in *L. colubrina* in Fiji (Pernetta 1977. Can. J. Zool. 55:1612–1619). This new observation adds further support to the interpretation of decapod crustaceans as potentially important predators of marine snakes in general (Voris and Jeffries 1995. J. Trop. Ecol.11:569–576).

Submitted by **AMY CUNKELMAN** (e-mail: amy.cunkelman@villanova.edu) and **AARON M. BAUER** (e-mail: aaron.bauer@villanova.edu), Department of Biology, Villanova University, 800 Lancaster Avenue, Villanova, Pennsylvania 19085, USA.

MASTICOPHIS FLAGELLUM (Coachwhip). **OPHIOPHAGY.** *Masticophis flagellum* is known to have a varied diet, which includes a number of snake species (see Beaman and Harris 2002. Herpetol. Rev. 33:214–215), and the western subspecies *M. f. piceus* has even been reported to prey upon a juvenile *Crotalus adamanteus* in captivity (Klauber 1956. Rattlesnakes: their Habits, Life Histories, and Influence on Mankind, 2 vols. Univ. of California Press, 1533 pp.). Herein we report the first instance, to the best of our knowledge, of a *M. flagellum* preying upon a *C. adamanteus* in the field.

On 28 September 2004 at ca. 1600 h, a large *M. flagellum* (ca. 180 cm total length) was observed ingesting a small *C. adamanteus* (ca. 80 cm total length) in an open grassland habitat on the Camp

Shelby Training Site, Perry County, Mississippi, USA. When first discovered, the rattlesnake was already one-third ingested, and after 10 minutes, it was half ingested. At this point an attempt was made to capture the *M. flagellum*; however, it quickly moved into a Gopher Tortoise (*Gopherus polyphemus*) burrow. For that reason, measurements and sexes of both snakes were not recorded. The entire time the incident was observed the tail of the prey snake was rattling. While traveling to the burrow, the *M. flagellum* had its head elevated with the rattlesnake hanging out of its mouth.

Submitted by **MATTHEW G. HINDERLITER** (e-mail: mhinderliter@tnc.org) and **JAMES R. LEE**, Camp Shelby Field Office, The Nature Conservancy, CSTS-ENV Building 6678, Camp Shelby, Mississippi 39407, USA.

MASTICOPHIS LATERALIS EURYXANTHUS (Alameda Whipsnake). **HABITAT.** *Masticophis lateralis euryxanthus* have been reported to be associated with a narrowly defined set of habitat characteristics; specifically chaparral and scrub plant communities on northeast, east, southeast, south, and southwest facing slopes (Swaim 1994. Unpubl. Masters Thesis, California State University, Hayward, CA. 140 pp.; United States Fish and Wildlife Service [USFWS] 1997. Federal Register 62:64306–64320; USFWS 2002. Draft recovery plan for chaparral and scrub community species east of the San Francisco Bay, California, Portland, Oregon 306 pp.). However, the USFWS reported that the habitat description for this subspecies "may have been biased" by focused trapping efforts (USFWS 2000. Federal Register 65:58933–58962). Swaim and McGinnis (1992. Trans. West. Sect. Wildl. Soc. 28:107–111) reported finding no *M. l. euryxanthus* on west-facing slopes and suggested a possible relationship to a lack of morning sun. However, Alvarez et al. (ms. in review, Trans. West. Sect. Wildl. Soc.) report that 32% of documented observations place *M. l. euryxanthus* in plant communities other than those described above. Herein, I present evidence that *M. l. euryxanthus* are found on a variety of slope aspects.

One hundred and twenty-seven records of free-ranging *M. l. euryxanthus* (and possible intergrades with *M. l. lateralis*) in Alameda and Contra Costa Counties (California) were reviewed by Alvarez et al. (*op. cit.*). These included specimens in the Museum of Vertebrate Zoology (MVZ) and California Academy of Sciences (CAS), reports from the California Natural Diversity Data Base (CNDDB), publicly accessible consulting reports from survey efforts, and personal communications from knowledgeable individuals (including my own observations). Slope aspect could be reliably determined for 82 of these observations. Data collected were transposed onto a commercial mapping program. Observations were deemed ambiguous (and not usable) if an error polygon associated with the observation placed the animal on multiple slope aspects. I visited every locality in 2004 to determine habitat type and confirm slope aspect. Seventeen of 82 observations (21%) were associated with west, north, and northwest slope aspects. These include three museum specimens (MVZ 128223, CAS 227730, CAS 201051); eight reported in the CNNDB, 13 reported by McGinnis (1990. Survey for the Alameda Whipsnake on the north-facing slope of the Kellogg Creek watershed west of Vasco Road, Contra Costa County, California, Unpubl. ms. 16 pp.), and two of my own observations. In addition to these documented records, two biologists report capturing more than 50 *M. l. euryxanthus* (collectively) on west and north-facing slopes (J. Sheppard and A. Murphy, pers. comm.).

The majority of *M. l. euryxanthus* observations reported in publicly accessible documents, databases, and collections do coincide with slope aspects reported by Swaim and McGinnis (1992, *op cit.*) and Swaim (1994, *op. cit.*). However, observations presented here indicate that *M. l. euryxanthus* uses virtually all slope aspects available, and data presented in Alvarez et al. (*op. cit.*) demonstrate that oak woodlands and annual grasslands are also occupied by these snakes. This information should be incorporated in conservation planning for this federally threatened snake (USFWS 1997. Federal Register 62:64306–64320). Specifically, chaparral, scrub, oak woodland, and grassland plant communities that occur within the range of *M. l. euryxanthus* should be recognized as potentially occupied habitat, irrespective of slope aspect.

I thank M. A. Shea, J. L. Sheppard, and W. K. Weber for helpful reviews, J. L. Sheppard and A. Murphy for sharing observations, and CNDDB, MVZ, and CAS for access to institutional records.

Submitted by **JEFF A. ALVAREZ**, The Wildlife Project, P.O. Box 579805, Modesto, California 95357, USA; e-mail: azoologist@SBCglobal.net.

NERODIA FASCIATA (Southern Watersnake). **DIET**. Gibbons and Dorcas (2004. North American Watersnakes: A Natural History. Univ. of Oklahoma Press, Norman, Oklahoma. 438 pp.) summarized the literature on dietary records of *Nerodia fasciata*. The primary prey of this species are fish (e.g., *Gambusia affinis*) and amphibians (primarily frogs) (Gibbons and Dorcas, *op cit.*, Dundee and Rossman 1989. The Amphibians and Reptiles of Louisiana. Louisiana State University Press, Baton Rouge, Louisiana. 300 pp.). Several aquatic salamanders are recorded in the diet of *N. fasciata*, however, of the family Sirenidae, only *Siren lacertina* have been documented in the diet of this species (Gibbons and Dorcas, *op cit.*). This is especially noteworthy because the ranges of sirens and *N. fasciata* overlap extensively (Conant and Collins 1991. A Field Guide to Reptiles and Amphibians of Eastern/ Central North America. Houghton Mifflin Company, Boston, Massachusetts. 608 pp.).

On 14 March 2002 at 2056 h, an adult female *N. fasciata* (SVL 570 mm, TL 162 mm, 197 g without prey item) was found foraging in floating marsh habitat at Jean Lafitte National Historical Park and Preserve, Barataria Unit, Jefferson Parish, Louisiana, USA. The snake had an obvious bulge in its stomach and was retained until the following morning for measurements and determination of stomach contents. The stomach contents were obtained by forced regurgitation. A partially digested *Siren intermedia* (total length 225 mm, 19 g) was found swallowed tail-first. To our knowledge, this observation represents the first documentation of *N. fasciata* predation upon the commonly syntopic prey species, *S. intermedia*.

We thank the National Park Service (David Muth) for permits and financial support of the herpetological inventory.

St. Paul, Minnesota 55117, USA (e-mail: reptilia74@aol.com); **KATHERINE E. MARIER**, 13165 Marigold St. NW, Coon Rapids, Minnesota 55448, USA. Present address (NJA): Department of Biological Sciences, Idaho State University, Pocatello, Idaho 83209, USA (e-mail: andenoah@isu.edu).

OPHEODRYS AESTIVUS (Rough Green Snake). **PREDATION**. Despite their arboreal habits (Plummer 1981. J. Herpetol. 15:425–432) and consequent proximity to the nests of many birds, bird eggs have not been documented in the diet of *Opheodrys aestivus*. By most accounts, diet consists primarily (if not exclusively) of invertebrates (Plummer, *op. cit.*).

On 11 May 2005 at 0945 h, we watched an adult *O. aestivus* (ca. 600 mm TL) depredate the nest of a *Vireo atricapilla* (Black-capped Vireo). The nest was 0.68 m above ground in a *Quercus sinuata* (Shin Oak) and contained two eggs. The *O. aestivus* launched itself 0.76 m towards the nest from a neighboring *Q. sinuata*, where it had been sitting at approximately the same height as the nest. Upon landing in the *Q. sinuata* that held the nest, the *O. aestivus* went directly inside the nest and immediately swallowed an egg. Because *V. atricapilla* is endangered (USFWS 1987. Federal Register 52:37,420–37,423) we removed the *O. aestivus* and released it >1 m from the nest. However, when we checked the nest later that day, the second egg was gone. We assume that the snake returned and ate it.

This observation documents *O. aestivus* predation on eggs for the first time. Further, this observation adds *O. aestivus* to a growing list of snakes that prey on *V. atricapilla* nests (*Agkistrodon contortrix* [Noa 2005. Demographic Differences of Black-capped Vireos (*Vireo atricapilla*) in Two Habitat Types in Central Texas. M.S. thesis, Univ. of Vermont, Burlington. 55 pp.], *Elaphe obsolete*, and *Masticophis flagellum* [Stake and Cimprich 2003. Condor 105:348–357]).

Submitted by **SELINA NELSON**, **RICHARD M. KOSTECKE** (e-mail: rkostecke@tnc.org), and **DAVID A. CIMPRICH** (e-mail: dcimprich@tnc.org), The Nature Conservancy, P.O. Box 5190, Fort Hood, Texas 76544-0190, USA.

PHALOTRIS MATOGROSSENSIS (False Coral Snake). **DIET**. Insects, earthworms, molluscs, frogs, lizards, amphisbaenians, and snakes (in captivity) have been reported in the diet of snakes of the genus *Phalotris* (Amaral 1977. Serpentes do Brasil – Iconografia colorida. Ed. Melhoramentos/EDUSP. São Paulo. 247 pp.; Lema et al. 2005. Iheringia Ser. Zool. 95:65–78). However, some of these items need confirmation and there are few reports of feeding observations in wild. Here we report an observation of *P. matogrossensis* feeding in nature.

On 8 December 2000 at 1400 h Fábio R. Luiz encountered a *Phalotris matogrossensis* (310 mm SVL, 6.5 g) in the process of swallowing an *Amphisbaena* sp. (245 mm SVL, 9 g) in an open area at Vale do Formoso farm, Municipality of Ribas do Rio Pardo, Mato Grosso do Sul States, Brazil. The amphisbaenian was collected dead, possibly because of envenomation during subjugation by snake. This is the first record of *P. matogrossensis* eating an *Amphisbaena* sp. The specimens are in the Museu de História Natural Capão da Imbuia (MHNCI), in Curitiba Municipality, Paraná, Brazil (*P. tricolor*, MHNCI 10.446; *Amphisbaena* sp., 10.447).

We thank F. R. Luiz and J. C. Moura-Leite for assistance.

Cuiabá No. 3.087, Jardim Clodoaldo, Cacoal – RO, 78.976-005, Brazil.

PHALOTRIS MERTENSI (False Coral Snake) and ***AMPHISBAENA MERTENSI*** (NCN). **PREDATION**. Both *Phalotris mertensi* and *Amphisbaena mertensi* display fossorial habits, and data concerning feeding behavior are rare. Ribas and Brito (2003. Joint Meeting of Icthyologists and Herpetologists, abstract) reported predation on a *A. mertensi* (SVL = 250 mm, tail = 10 mm, mass = 8.78 g) by a *P. mertensi* (SVL = 350 mm, tail = 30 mm, mass = 12.73 g) in Rio Claro, São Paulo state, Brazil. Ingestion was head-first. On July 2002, at ca. 1700 h at Tietê (23º06'S, 47º42'W, São Paulo state, Brazil, 508 m elev.), an adult *P. mertensi*, ca. 500 mm total length, was found swallowing an adult *A. mertensi*, ca. 350 mm TL. Immediately, the snake regurgitated the freshly-killed amphisbaenian and escaped.

I thank Valdir José Germano and Hebert Ferrarezzi, Laboratório de Herpetologia, Instituto Butantan, for verification of snake and amphisbaenian species identification, and Veranice Galha for photography.

Submitted by **MARCELO RIBEIRO DUARTE**, Laboratório de Herpetologia, Instituto Butantan, Av. Vital Brazil, 1500, CEP 05503-900, São Paulo, SP, Brazil; mrduarte@butantan.gov.br.

PHALOTRIS TRILINEATUS (NCN). **PREDATION.** At ca. 1000 h on 30 October 2001 in a swamp-grassland area at Arroio Teixeira, northeast of Rio Grande do Sul, Brazil, I observed a male American Kestrel (*Falco sparverius*) flying with a snake (*Phalotris trilineatus*) in its claws. The kestrel alighted on a wire near a secondary road and started to pluck out pieces of flesh. The snake was still alive when the kestrel started to eat it, an uncommon behavior for this falcon, which usually kills vertebrate preys before eating. As a car drove by on the road, the kestrel flew off, leaving the still-living snake hanging on the wire. When the kestrel returned to its prey, the snake attempted defensive strikes and fell to the ground. The kestrel hovered for ca. 1 min and flew away.

Although *Falco sparverius* is known to prey on small snakes, I am unaware of any reports for predation on *Phalotris trilineatus*. The snake (259 mm total length) was pecked on two body regions: 18 mm and 90 mm behind the rostrum. In both regions the ribs were broken and the viscera and flesh were plucked out. The snake was deposited in the herpetological collection of the Departamento de Zoologia of the Universidade Federal do Rio Grande do Sul (UFRGS 3563), Porto Alegre, Rio Grande do Sul, Brazil. I thank Gilberto Alves de Souza Filho for the snake identification and Paulo Hartmann for comments.

SIBON NEBULATUS (Common Snaileater). **MAXIMUM SIZE.** *Sibon nebulatus* is one of the larger members of its genus and reaches a maximum length of 850 mm total length (Solorzano 2004. Snakes of Costa Rica: Distribution, Taxonomy, and Natural History. Instituto Nacional de Biodiversidad, Santo Domingo de Heredia, Costa Rica. 791 pp.). At 1830 h on 31 July 2005 we found an adult female *S. nebulatus* crossing Barrigon Road ca. 0.9 km south of Parque Nacional General Omar Torrijos Herrera (Cocle Province, Panama). The live snake measured 779 mm SVL, 234 mm tail length, and weighed 128.0 g. At 1013 mm total length, this specimen (Museo de Vertebrados de la Universidad de Panama; MVUP 1863) is the longest known *S. nebulatus*. In addition, palpation suggested that the female was gravid and contained seven eggs.

We thank E. Griffith, H. Ross, the National Science Foundation (DEB # 0234386 and 021385), the Smithsonian Tropical Research Institute, Parque Nacional Omar Torrijos, and Autoridad Nacional del Ambiente for assistance, permissions, and/or funding.

THAMNODYNASTES STRIGILIS (NCN). **PREY**. *Thamnodynastes strigilis* is a terrestrial colubrid distributed from central-western and northeastern Brazil to Uruguay (Franco and Ferreira 2002. Phyllomedusa 1:57–74). The few reports on the feeding habits of snakes in the genus *Thamnodynastes* suggest they feed mainly on anurans (especially hylids and lepdodactylids) but also on rodents, fish, and lizards (Bernarde et al. 2000. Rev. Brasil. Biol. 60:695–699; França and Souza et al. 2003. Herpetol. Rev. 34:378; Kopp and Wachlewski 2005. Herpetol. Rev. 36:71–72; Lema et al. 1983. Comun. Mus. Cienc. PUC-RS 26:41–121; Rocha and Vrcibradic 1998. Cienc. Cult. 50:364–368; Ruffato et al. 2003. Phyllomedusa 2:27–34).

We examined the stomachs of eight specimens (MNRJ 9793 and 13383–13389) of *T. strigilis* (averaging 473.2 ± 80.2 mm SVL) for the presence of prey remains. All eight specimens were collected in and around a temporary pond in secondary Atlantic Rainforest surrounding Vila Dois Rios, Ilha Grande (23°11'S; 44°12'W), off the coast of the state of Rio de Janeiro (Brazil) during the evening (1900–2330 h) over a seven-year period (Apr/96, Dec/97, Oct/98, Jul/99, Oct/99, Oct/02). We discovered prey remains in four specimens. One (MNRJ 9793; female; 518 mm SVL; Oct/02) contained a *Physalaemus signifier* (26 mm SVL) and the tail and 3 limbs of a lizard (*Gymnodactylus darwinii*). A second specimen (MNRJ 13384; male; 565.6 mm SVL; Jul/05) contained the hind limbs of a *Eleutherodactylus guentheri* (leptodactylidae). A third specimen (MNRJ 13387; female; 360 mm SVL; Oct/01) contained a male (37.2 mm SVL) and female (27.3 mm SVL) *Scinax trapicheiroi* (hylidae). The fourth specimen (MNRJ 13383; female; 491 mm SVL; Oct/99) contained a *Chiasmocleis* sp. (Microhylidae; 20 mm SVL).

This is the first report of a microhylid frog (*Chiasmocleis* sp.) in the diet of *Thamnodynastes*. Frogs of the genus *Physalaemus* and the lizard *Gymnodactylus darwinii* have been previously reported as prey of other species of *Thamnodynastes* (Rocha and Vrcibradic, *op.cit.*; Bernarde et al., *op. cit.*; Ruffato et al., *op. cit.*). These observations offer further support for the hypothesis that *Thamnodynastes* are important predators on anurans.

We thank D. Vrcibradic and F. L. Franco for assistance. The Conselho Nacional de Desenvolvimento Científico e Tecnológico – CNPq provided funding.

THAMNOPHIS ATRATUS (Aquatic Gartersnake). **PREDATION**. On 30 May 2004, JD and KR were conducting amphibian surveys along a stretch of Bennett Creek in Mendocino National Forest, Tehama County, California, USA (UTM Coordinates 531484 E, 4408974 N, Zone 10,NAD27, 336 m elev). The weather was clear with a light breeze; air temperature was 28°C, and the creek temperature was 22°C. At about 1300 h, two adult *Thamnophis atratus* were found sitting on a wet rock immediately adjacent to a small waterfall in the reek. Both snakes were loosely coiled in a striking posture, and had their heads near the water. The snakes appeared to be intently watching the water. The snakes were observed for 10 minutes during which time both snakes were observed to strike at smal fish as the fish attempted to swim up the waterfall. After one of the snakes was successful, it was captured with the fish still in its mouth. The fish was a California Roach (*Lavinia symmetricus* [=*Hesperoleucus symmetricus*]). The snake was 59.5 cm (SVL); the other snake was also captured and was 50.0 cm SVL. A video recording was obtained along with photographs of one snake catching a fish.

Lind and Welsh (1994. Anim. Behav. 48:1261–1273) reported that *T. atratus* foraging techniques varied ontogeneically, with juveniles (< 44.9 cm SVL) using both ambush and underwater substrate-crawling, and adults using underwater substrate-crawling almost exclusively. The snakes we observed were both adults, yet they were using an ambush style of foraging, somethng that Lind and Welsh found only once in 38 observations of adult *T. atratus* foraging.

Catching small fish as they ascended a small waterfall would require good visual acuity and a rapid strike. Alfaro (2002. Funct. Ecol. 16:204–215) reported that *T. couchii* aerial strike speed was more than five times that of *T. sirtalis*. Drummond (1985. Anim. Behav. 33:206–215) and Schaeffel and De Queiroz (1990. Copeia 1990:50–58) reported that the aquatic specialists *T. couchii* and *T. melanogaster* had superior vision compared with *T. sirtalis* and other *Thamnophis* with more terrestrial foraging modes. Both these factors would suggest that *T. atratus* would be particularly well adapted to the type of ambush foraging that we observed.

UROTHECA DECIPIENS (Collared Glass-tailed Snake). **DIET**. *Urotheca decipiens* is a small, diurnal, terrestrial snake that is reported to consume amphibians and small lizards (Solorzano 2004. Snakes of Costa Rica. Instituto Nacional de Biodiversidad, Santo Domingo de Heredia, Costa Rica. 791 pp.). At 2000 h on 22 September 2005 we found an adult female *U. decipiens* (240 mm SVL; 37 mm tail length; 6.8 g) moving through the leaf litter after dark in Omar Torrijos National Park (Cocle Province, Panama). A portion of the tail was missing, presumably lost as part of the antipredatory defense that is typical of the genus (Savage 2002. The Reptiles and Amphibians of Costa Rica. Univ. Chicago Press, Chicago, Illinois. 934 pp.). After collection the snake regurgitated the head and neck of a small *Sphaerodactylus* sp. This is the first report of *Sphaerodactylus* in the diet of *U. decipiens*, as well as the first report of *U. decipiens* in Cocle Province and Central Panama. In addition, our observation of the active snake at night suggests *U. decipiens* may not be entirely diurnal. The snake and its gut contents were deposited in the Circulo Herpetologico de Panama (*U. decipiens* CH 5975; *Sphaerodactylus* sp. CH 5976).

NOTOPHTHALAMUS VIRIDESCENS LOUISIANENSIS (Central Newt). USA: ARKANSAS: Union Co.: Beech Creek at St. Hwy. 160, ca. 3.2 km E of Mount Holly (Sec. 25, T16S, R18W).

unsuitable for oviposition by *S. albicans*. However, no significant negative relationship was recorded.

The patterns found show aggregation size to be remarkably constant by the standards of any vertebrate populations. The permanence of males in aggregation was high, and the little variation in aggregation size was explained by variations in the numbers of males entering the aggregation each month. The possibilility that aggregation size could be used as in index to population size is jeopardized by its high constancy and lack of relationship with rainfall patterns. Possibly aggregation size is rather controlled by social factors regulating the number of males calling at a time in any given place.

Acknowledgments.—We thank IBAMA (Instituto Brasileiro de Meio Ambiente e Recursos Naturais Renováveis) for allowing the work at Parque Nacional da Serra dos Orgãos; Instituto Nacional de Meteorologia (INEMET) for climatic data; Sergio Potsch de Carvalho e Silva for teaching on amphibians, for logistic support and co-supervising DN's MSc dissertation; the several colleagues, especially Fábio Nascimento, who helped in field work; Rômulo Barroso for company in all field work and discussions throughout the study; José P. Pombal Jr., William Magnusson, Jon Loman, Monique Van Sluys, Ronaldo Fernandes, Gunther Koehler and an anonymous referee for very useful comments on the manuscript; Jorge Luiz do Nascimento for ideas in this study and for financial support.

Abundance and Biomass of Twelve Species of Snakes Native to Northeastern Kansas

HENRY S. FITCH
University of Kansas Fitch Natural History Reservation
2060 East 1600 Road, Lawrence, Kansas 66044, USA

and

ALICE F. ECHELLE
Department of Zoology, Oklahoma State University
Stillwater, Oklahoma 74078, USA
e-mail: aechelle@juno.com

The purposes of this paper are to examine abundance and biomass estimates of the dozen most abundant snake species in our area of northeastern Kansas, and to relate these numbers to information reported in the literature. Hirth and King (1968) stated, "In spite of all the current interest in ecosystem ecology there is still a dearth of information concerning biomass densities of snakes in various habitats." Except for a few studies (e.g., Bonnet et al. 2002; Godley 1980; Hirth and King 1968; Reichenbach and Dalrymple 1986; Winne et al. 2005), the situation does not seem to have changed appreciably in the last 37 years.

Methods and Study Area

Snakes have been studied for the past 56 years on Kansas University's Natural History Reservation (FNHR) following establishment of the area as a reserve. Although protected from anthropogenic alterations, the area has undergone continual and progressive change due to natural ecological succession (Fitch 1999; Fitch et al. 1984, 2001, 2003b). The closing in of forest and elimination of open places associated with agriculture and grazing has been unfavorable for snakes. Several of the species have disappeared from this 239-hectare tract, and almost all species have been drastically reduced (Fitch 1999). The adjoining Nelson Environmental Study Area (NESA), acquired by the University in 1970, has provided a contrast to FNHR in terms of habitat stability. Invasion of woody vegetation is prevented on NESA by the regular mowing of blocks of former pasture and cultivated land, and as a result, existing snake populations resemble those found on FNHR in earlier stages of succession (Fitch 1999).

Sampling areas (House Field, Quarry Field, etc.) are described by Fitch (1999). Of the 12 censuses reported here, eight were from FNHR and were done in the earlier years of study (before 1979) except that for *Thamnophis sirtalis*. Of the remaining four species, *Carphophis vermis* was censused by Clark (1970) on private property adjoining FNHR and three, *Lampropeltis triangulum*, *L. calligaster*, and *Coluber constrictor*, were censused post-1990 on NESA.

Unless otherwise noted, density estimates are based on field records and censuses originally published in Fitch (1999) except for Clark's (1970) *Carphophis* figures. Mark-recapture records and the Petersen Index were the bases for the abundance estimates for most species, including *Agkistrodon contortrix* (Copperhead), *Carphophis vermis* (Western Wormsnake), *Coluber constrictor* (Racer), *Crotalus horridus* (Timber Rattlesnake), *Diadophis*

punctatus (Ring-necked Snake), *Nerodia sipedon* (Northern Watersnake), *Pantherophis obsoletus* (Black Ratsnake), *Pituophis catenifer* (Bullsnake), and *Thamnophis sirtalis* (Common Gartersnake). For the remaining three species, *Lampropeltis calligaster* (Prairie Kingsnake), *Lampropeltis triangulum* (Milksnake), and *Storeria dekayi* (DeKay's Brownsnake), densities were estimated from their respective numbers relative to one or more species with larger mark-recapture samples.

Weights are based on figures from Fitch (1999, Table 98). Number of snakes, weight, and biomass per hectare were log transformed for the regressions. Representative weight for each species is the midpoint between the means for the adults of both sexes (excluding gravid and recently parturient females). For the sake of consistency, only adult mass was used to calculate biomass from density, although immatures were present for every species censused (see Fitch 2000, for age pyramids for 10 of the species). Attempting to factor in mean mass across all sizes had the potential of introducing more bias than was inherent in excluding these other size classes. Relative abundance of life history stages varied markedly over each trapping season, but these seasonal fluctuations were not synchronized among species. Also, age composition of each species censused was partly a function of trapping method. For example, entrance holes of the wire funnel traps were mostly too small to allow entry of large adult Timber Rattlesnakes. In contrast, the traps were well suited to catch larger young and adults of the Common Gartersnake, while tiny neonates of this species easily passed through the quarter-inch mesh of the traps, and hence are missing from the trapping records. More information is available in Fitch (1999), including details of food habits and population fluctuations. Age structure pyramids and "standing crop" biomass estimates for 10 local snake species are presented in Fitch (2000).

Results

Dates of census, sampling area, abundance, mean adult weights, and other numbers based on these figures are listed in Table 1. The following list explains the specifics of the abundance estimate for each species.

Agkistrodon contortrix—18.6/ha is the mean of ten censuses in 1977 on FNHR, five for House Field and five for Quarry Field.

Carphophis vermis—729/ha in 1966 on private property 1 km west of FNHR headquarters (Clark 1970). This was the highest density estimate given by Clark (1970). We use it because it was derived with the Petersen Index, as were the estimates for the other species reported here. Clark obtained a lower estimate with the Hayne modification of the Lincoln Index, but this modification is apparently more appropriate for small mammals than for snakes (Carpenter 1952).

Coluber constrictor—13.2/ha based on five separate 0.5-month sampling periods in 1991–1994 on the northwestern pens area of NESA. These five were chosen from a number of available censuses for this species (Fitch 1999) because all included more than one recapture, and shorter sampling periods generally seem to yield the most reliable estimates for this species.

Crotalus horridus—0.2/ha for the northwestern quarter of FNHR in the early 1960s from a Petersen Index estimate (previously unpublished) based on only two recaptured rattlesnakes, at a time when the species was already dwindling. The last capture of *C. horridus* from FNHR was in 1964. By contrast, 12 were captured from a 10-ha area of NESA (Biotic Succession Area) in the years 1990 through 2002 (Fitch et al. 2003). Additionally, in the spring of 2003, 26 were captured along a rock outcrop about 100 m long near Frank B. Cross Reservoir, in an area adjoining NESA on the east (Fitch et al. 2004).

Diadophis punctatus—Many different censuses are available for the once-abundant Ring-necked Snake (Fitch 1999). Seven were done in Quarry Field in 1966–67 and 1969–70, with sampling periods ranging from 0.5 to 2 months. Eliminating the extreme lowest and highest estimates (597 and 4000/ha) gave a range of 791–2039/ha and a mean of 1325/ha. An additional eight censuses were from House Field with sampling periods ranging from 0.5 to 3 months (1965–1967); excluding the lowest and highest estimates (262 and 1792) gave a mean of 1224/ha (range = 773–1761). Averaging the means for these two areas, both on FNHR, gives an overall mean of 1275/ha.

Lampropeltis calligaster—2.5/ha, 1990–1997, on the northwestern pens area of NESA. This estimate is the average of 1.6/ha (based on ratio of capture records compared to *Thamnophis*) and 3.3/ha (compared to *Coluber*). Since 2001, 14 *L. calligaster* have been captured on NESA, and only two individuals (both in 2002) have been found on FNHR.

Lampropeltis triangulum—0.6/ha, 1990–1997, on the northwestern pens area of NESA. This estimate is the average of 0.52/ha (compared to *Thamnophis*) and 0.73/ha (compared to *Coluber*). The last capture of *L. triangulum* on FNHR was in 1999. Since 2001, 17 have been captured on NESA.

Nerodia sipedon—The majority of records were concentrated about the FNHR pond, but a few were scattered over a much larger area, reflecting the fact that these snakes travel, following the water supply in drainage systems. The Petersen Index indicated 10 snakes for 1978. The area covered was approximately 25 ha, resulting in an estimate of 0.4/ha (previously unpublished).

Pantherophis obsoletus—Records for the Black Ratsnake are perhaps not sufficiently concentrated in time to yield a reliable sample free from the effect of temporal change, although survivorship in this species is longer than in most. Hence the Petersen Index estimate may have some validity, despite the long sampling period (1950 through 1960) and the large area involved (129.5 ha), approximately the northern half of the Reservation. Based on varying sampling and resampling times, densities of 0.9 to 3.6/ha have been calculated (Fitch 1999, Table 101). The average of these, 2.3/ha, is used for this study.

Pituophis catenifer—From the start, the Bullsnake was unfavorably affected by successional changes, and it dwindled through the 1950s and 1960s (Fitch 2003). Censuses, taken almost entirely from the northwest quarter-section (64.7 ha) of FNHR in 1958, 1959, 1963, 1964, and 1966 averaged 38.5 snakes per year, giving an estimate (previously unpublished) of 0.60 snakes/ha. The last FNHR capture of this species was in 1984. Six were captured on NESA during the period 1997–2002.

Storeria dekayi—Estimated at 42/ha in the House Field-Quarry Field area, 1966–67 and 1969–70, based on a 3.3% ratio of brown snakes to the more readily censused *Diadophis*.

Thamnophis sirtalis—15.4/ha in House Field, 1988–1997. Although the Common Gartersnake was abundant enough to provide a surfeit of samples from several areas, only samples from

TABLE 1. Abundance and biomass of 12 snake species on the Fitch Natural History Reservation (FNHR), a plot of private land adjoining FNHR (*Carphophis*), and Nelson Environmental Study Area (NESA).

Species	Site of census	Year(s) of census	Number individuals/ha	Percentage of total number of snakes	Mean adult weight (g)	Biomass per hectare (g/ha)	Percentage of total snake biomass/ha
Agkistrodon contortrix	FNHR	1977	18.6	0.89	150	2790	13.4
Carphophis vermis	1 km W FNHR	1966	729.0	34.72	7	5103	24.5
Coluber constrictor	NESA	1991-1994	13.2	0.63	140	1848	8.9
Crotalus horridus	FNHR	1960-1963	0.2	0.01	713	143	0.7
Diadophis punctatus	FNHR	1965-67 1969–70	1275.0	60.72	6	7650	36.7
Lampropeltis calligaster	NESA	1990-1997	2.5	0.12	202	505	2.4
Lampropeltis triangulum	NESA	1990-1997	0.6	0.03	73	44	0.2
Nerodia sipedon	FNHR	1978	0.4	0.02	202	81	0.4
Pantherophis obsoletus	FNHR	1950's	2.3	0.11	392	902	4.3
Pituophis catenifer	FNHR	1958-1966	0.6	0.03	671	403	1.9
Storeria dekayi	FNHR	1966-67 1969–70	42.0	2.00	5	210	1.0
Thamnophis sirtalis	FNHR	1988-1997	15.4	0.73	77	1186	5.7

House Field (10 ha area, FNHR) are reported here. In this area, snakes were found beneath shelters, and the hand captures included first-year young that can escape through quarter-inch mesh of live traps used, for example, at the NESA site. Of 44 census figures available from 1985–1997 (Fitch 1999), 13 were selected because each included more than one recapture and each was conducted in approximately two consecutive months of sampling (first month for primary sample followed by a 3–4 week re-sampling period). Shorter and consecutive sampling periods are probably more reliable for this species because longer sampling periods may result in inflated estimates (Fitch 1999).

DISCUSSION

The mark-recapture method of assessing population size is, in most cases, the most available method for assessing the numbers of a reasonably abundant species. However, numbers acquired through this approach are perhaps most appropriately compared for similarities/differences in orders of magnitude (Fitch 1975). A further caveat is that not all censuses were completed in exactly the same area and time for each of the 12 species. However, most of those from FNHR were done in the same or overlapping areas of the Reservation before ecological succession had resulted in shrub/forest encroachment (Fitch et al. 2001). The three censuses on NESA were done between 1990–1997; all three were at the same site, one that resembled earlier stages of succession on FNHR. For these reasons, we discuss these figures as if they were acquired from the same area in the same years. Our premise is that the numbers reported here are representative of relative snake abundance during the earlier stages of succession on FNHR.

Among the 12 species of FNHR/NESA snakes yielding sufficient data (Table 1, Fig.1), there was a statistically significant inverse relationship ($r = - 0.85$, $P < 0.001$) between typical adult weight of each species and number of snakes/ha (Fig. 1), implying that smaller snakes tend to be more abundant than larger species. There was also a statistically significant ($r = 0.82$, $P = 0.001$) relationship between number of individuals/ha and biomass/ha, suggesting that the more abundant species tend to form a larger portion of the snake biomass per unit area.

Consistent with the inverse relationship between size of snake and number/ha, the highest population numbers were recorded for the three species of smallest snakes. These were also the only species specializing in a diet of earthworms and/or slugs (Fitch 1999). *Diadophis punctatus* outnumbered (60% of total numbers) the population estimates for all other species combined. Its numbers

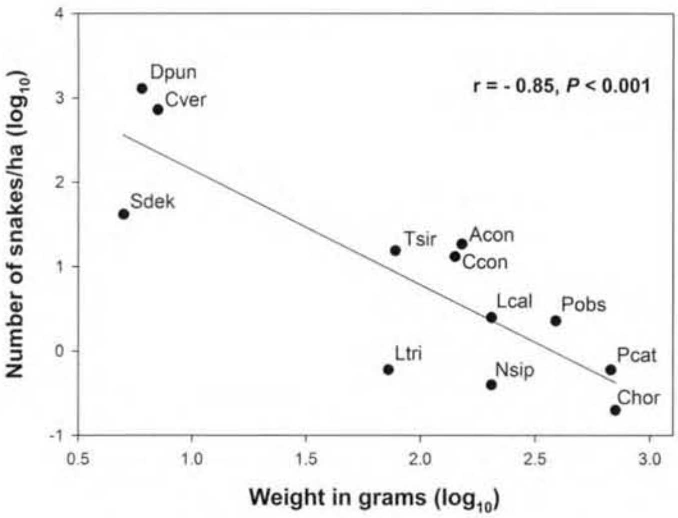

FIG. 1. Relationship between a typical adult weight of a snake species and number per unit area. Species codes (in parentheses) are as follows: *Agkistrodon contortrix* (Acon), *Carphophis vermis* (Cver), *Coluber constrictor* (Ccon), *Crotalus horridus* (Chor), *Diadophis punctatus* (Dpun), *Lampropeltis calligaster* (Pcal), *Lampropeltis triangulum* (Ltri), *Nerodia sipedon* (Nsip), *Pantherophis obsoletus* (Pobs), *Pituophis catenifer* (Pcat), *Storeria dekayi* (Sdek), and *Thamnophis sirtalis* (Tsir).

(mean 1275/ha) are comparable to those (1289/ha, censused by quadrat counts) reported by Godley (1980) for the Striped Swamp Snake, *Regina alleni*, in two water hyacinth-choked canals in southern Florida. To our knowledge, these figures are the highest known for any North American snake species, excluding reproductive and denning aggregations. Godley (1980) stated that his estimated mean standing crop for the *Regina* population (30.8 kg/ha) was greater than that known for any snake species; his estimate far exceeds our highest (7.65 kg/ha for *Diadophis*). In a study of another diminutive species, Clark and Fleet (1976) reported a range of 229 to 348/ha (mark/recapture, Lincoln Index) for the Rough Earthsnake, *Virginia striatula*. Like *Diadophis* in northeast Kansas, *Virginia* in eastern Texas apparently specializes in a diet of earthworms (Clark and Fleet 1976).

The second and third most abundant species were *Carphophis* and *Storeria*. Excluding *Diadophis*, wormsnakes was more abundant (729/ha) than all remaining species combined, and accounted for 35% of the total snakes (24% of total snake biomass). The diminutive natricine, *Storeria dekayi* (42/ha), was several times more abundant than an estimate (14/ha) based on mark-recapture for the same species in Ontario, Canada (Freedman and Catling 1978), but it should be noted that our estimate was indirect, based on a ratio to the more adequately sampled *Diadophis*.

Among the remaining nine species, primary prey consisted of vertebrates except for first-year garter snakes that tended to feed predominantly on earthworms (Fitch 1999). Among these nine species, four (Timber Rattlesnake, Northern Watersnake, Milksnake, Bullsnake) occurred at densities of less than one per hectare. Even at such low densities, the Timber Rattlesnake contributed 3–4 times the biomass/ha of that estimated by Hirth and King (1968) for a congener, the Great Basin Rattlesnake, *C. oreganus lutosus*, in desert habitat of northwestern Utah. *Nerodia* was fairly localized around the FNHR pond and associated waterways. *Pituophis*, *Crotalus*, and *Lampropeltis triangulum* were among the first to disappear from FNHR as succession progressed, and dense undergrowth and unbroken forest canopy invaded previously open fields and forest-edge habitat. Although the rattlesnake is a forest inhabitant, it apparently requires open sunny places for basking. Local Milksnakes prefer open woodland or forest edge with flat rocks, and the Bullsnake requires short-grass habitat. Pocket gophers (*Geomys bursarius*) and Five-lined Skinks (*Eumeces fasciatus*), favored prey for, respectively, Bullsnakes and Milksnakes, also disappeared or became scarce in the early years of FNHR succession (Fitch 1999; Kettle, Fitch, and Pittman, unpubl. ms.).

Despite relatively low abundances (< 3/ha), *Lampropeltis calligaster* and *Pantherophis obsoletus*, particularly the latter because of its greater bulk, constituted a moderate proportion of the total biomass represented by the nine larger snake species. Our figure of 2.3/ha for the Black Ratsnake is comparable to the density (3.9–4.2/ha) reported by Weatherhead and Haysack (1989) for a population at the northern edge of the species' range in eastern Ontario. Of the less abundant forms so far discussed, the Black Ratsnake is the only species that seemed to maintain a relatively stable population despite the successional changes on FNHR. The Prairie Kingsnake, by contrast, disappeared from FNHR as encroachment of brush and forest replaced its preferred tallgrass habitat.

The three remaining species, the Copperhead, Racer, and Common Gartersnake, were all prominent members of the local snake fauna. Because they were present in approximately comparable numbers, their relative contributions to the overall snake biomass were determined more by weight than by large differences in abundance. The average Copperhead weighed about twice as much as a Common Gartersnake and slightly more than the Racer, thus Copperheads constituted the most substantial portion (35%) of the biomass of the nine larger species, followed by the Racer (23%) and the Common Gartersnake (15%). Hirth and King (1968) reported a mid-summer density of 49g/ha for *Coluber constrictor mormon*, in desert habitat in northwestern Utah, a figure that seems strikingly low when compared with our figure of 1848g/ha for *C. c. flavivientris* in northeastern Kansas. With the caution that fall samples "...may be subject to minimum bias compared with samples collected at other times of year...", Fitch (2000) reported a much lower density (4.9/ha) and mean weight (103.6g) for fall samples of Copperheads than we report here. This difference reemphasizes the fact that local populations show large fluctuations in abundance and that census figures are rough approximations best used for relative comparisons and assessed in terms of orders of magnitude difference.

Our estimate of 15.4/ha for *Thamnophis sirtalis* is well within the range of values reported for this species: 1.7 in British Columbia (Farr 1988 as cited by Rossman et al. 1996) and 89 in Ohio (Reichenbach and Dalrymple 1986). The latter study estimated a biomass density of 2.8–5.5 kg/ha for *T. sirtalis* in Ohio, 2.3–4.6 times greater than our estimate for Kansas garter snakes. Among those snake species that have been abundant on FNHR, the Common Gartersnake has perhaps been the most persistent, and was one of the few species of this study that maintained sufficiently high population numbers to produce a useful FNHR estimate in the 1990's. Among the 12 snakes we studied, this species might

be considered the most generalized in food habits, as it consumes invertebrates, amphibians, mammals, and birds. Although found in field habitats, it is also relatively tolerant of shade, and, as stated by Fitch (1999, Table 102), its population fluctuations seem to be more affected by annual weather changes than by succession. Such plasticity helps explain the wide geographic range and high abundances of this species.

Parker and Plummer (1987) and Iverson (1982) provide general reviews of snake densities, and Ernst and Barbour (1989) and Rossman et al. (1996) summarize the data for various species of *Thamnophis*. A comparison of the numbers reveals extensive inter- and intra-specific variation in density patterns. As documented for snakes in the vicinity of FNHR, the extent of intraspecific fluctuations in a single area can rival that attributable to geographic or interspecific variation (Fitch 1999).

Acknowledgments.—We thank those who, as graduate students, contributed with their own studies of snake populations on or near the Reservation and have since maintained enthusiasm in this endeavor as is evidenced by their publications, including D. R. Clark, R. R. Fleet, W. S. Parker, G. R. Pisani, D. W. Platt, M. V. Plummer, and R. A. Seigel. Thanks also to S. F. Fox, J. F. Husak, and W. D. Kettle for their helpful discussions, and to A. A. Echelle, R. N. Reed and three anonymous reviewers for advice and critical reading of the manuscript. Finally, thanks are due to V. R. Fitch who helped with many aspects of the work reported in this paper.

and
RAFAEL AGUILAR
Manantiales 14, Barrio Santo Domingo
Tepoztlan, Morelos, Mexico

Recently obtained tadpoles from the vicinity of Ixtlan de Juarez, Sierra Juarez, Oaxaca, Mexico, were raised in captivity and determined to be those of *Plectrohyla hazelae*. Herein, we describe the tadpole of *P. hazelae*.

All the tadpoles (UMMZ 236001–02) were collected on 7 May 2004, on muddy bottoms of shallow pools in one small creek 3.8 km from "Rancho Tejas," Sierra de Juarez, on the Ixtlan de Juarez-Rancho Tejas road (17°18'96", 96°26'61"; 1900 m elev.). The tadpoles were taken to Mexico City (2400 m) and raised to adult stage except for few which were killed in 10% formalin at stages 30, 34, 36, 38, 39, 42, and 43 (Gosner 1960).Terminology and

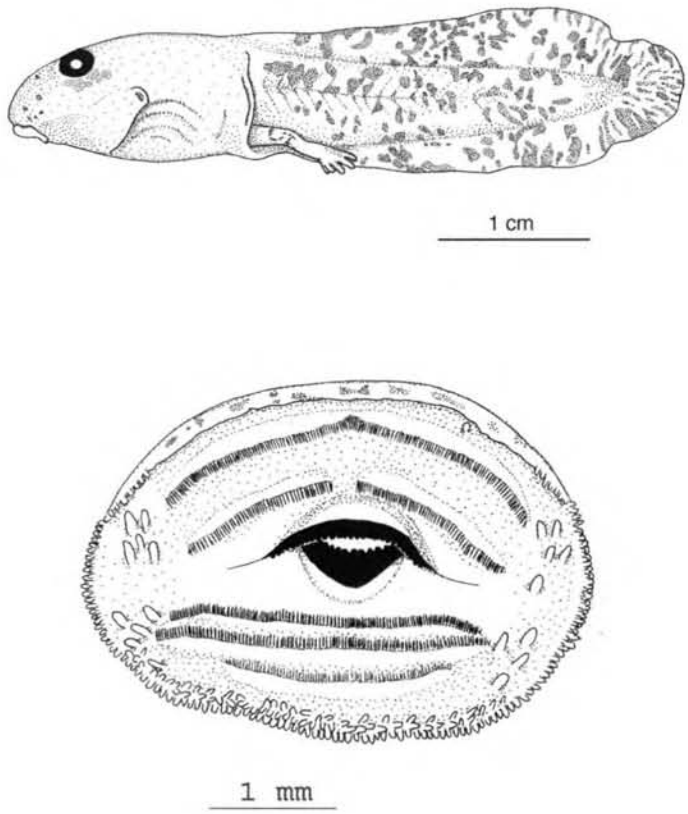

FIG. 1. Tadpole and oral disc of *Hyla hazelae* (Stage 38) (UMMZ).

measurements follow those proposed by Altig and McDiarmid (1999). Acronyms as follows: UMMZ = University of Michigan Museum of Zoology.

A typical tadpole in Stage 38 (Gosner 1960) (UMMZ 236001; Fig. 1; measurements in mm): body length 15.6; tail length 29.7; total length 45.3; body slightly depressed; snout round in dorsal view and profile; eyes large (eye diameter 2.6), dorsolateral, bulgy, separated by a distance of 3.1; nostrils separated by a distance of 3.4, slightly closer to eyes than to tip of snout; spiracle sinistral, C-type (Fig. 3.1 in Altig and McDiarmid 1999), directed posterodorsally, angled 80° with respect to longitudinal axis of body, opening below midline of body and half way between tip of snout and posterior end of body; vent tube dextral, G-type (Fig. 3.5 in Altig and McDiarmid 1999); width of caudal musculature 5.1; dorsal fin extending slightly onto body; maximum height of tail located at posterior 3/4 of tail; tip of tail round (partly damaged in this individual).

Oral disc medium size (oral disc diameter/max. body width = 0.5), elliptical, ventrally located, not emarginate, bordered by marginal papillae laterally and posteriorly; marginal papillae on lateral and posterolateral parts of oral disc biserial; marginal papillae of posterior part of oral disk slightly offset, intercalated, biserial to triserial; 4 to 5 large submarginal papillae on each side of oral disc; labial tooth row formula 2(2)/3; gap of A-2 1/5 of row length; lengths of A-1 and P-2 equal, reaching submarginal papilla; relative lengths of posterior teeth rows P-2>P-1>P-3; P-3 distinctively shorter than other rows; labial teeth of P-3 shorter than those of other rows; labial tooth ridges rigid; upper jaw sheaths poorly keratinized, bearing small round serrations but not lateral processes; lower jaw sheath moderately keratinized, V-shaped, bearing 20–25 small round serrations.

In life, body dark gray with slightly darker blotches. In preservative, body gray brown, tail musculature gray beige, and blotches dark brown; large dark blotches scattered on dorsal and lateral parts of body, anterior surface of oral disc, dorsum of legs, tail musculature and fins; fins more pigmented on posterior 2/3 of tail than on anterior 1/3; tail musculature more pigmented on anterior than posterior half of tail; rims of vent, nostrils, and spiracle darkly pigmented.

Keratin can be present or absent on both jaw sheaths, or present only on the lower jaw. The keratin on the lower jaw can form a narrow continuous arch or two discontinuous patches. The marginal papillae can be well or poorly defined on the anterior edge of the oral disc. In dorsal view, the body is ovoid (Stages 36 and younger) or elongated (Stages 37 and older).

The tadpoles of *Plectrohyla hazelae* differ from those of other stream-dwelling species of *Plectrohyla* from the Sierra de Juarez (i.e., *P. bistincta*, *P. crassa*, *P. calthula*, *P. celata*, *P. cembra*, *P. cyanomma*) by having a tail with its highest point at the posterior 2/3 and by lacking one or several rows of large submarginal papillae anterior to A-1 and/or posterior to P-3.

Acknowledgments.—We thank John Megahan for helping with figures and Oscar Flores for collecting permits.

Checklist and Comments on the Terrestrial Reptile Fauna of Kau Wildlife Area, Papua New Guinea

CHRISTOPHER C. AUSTIN
Museum of Natural Science, 119 Foster Hall, Louisiana State University Baton Rouge, Louisiana 70803, USA
e-mail: ccaustin@lsu.edu

The island of New Guinea has been identified as a megadiverse region because of its extraordinary biodiversity and highly endemic biota (Mittermeier and Mittermeier 1997). New Guinea, the world's largest and highest tropical island, occupies less than 1% of global land area yet 5–7% of the world's biodiversity is found on the island (Beehler 1993; Dinerstein and Wikramanayake 1993; Mack 1998; Myers et al. 2000). The herpetofauna of New Guinea currently known to science accounts for about 5% of the world's reptile and amphibian diversity (Allison et al. 1998). Remarkably, this is an underestimate of true diversity; it is predicted that 30–60% of the reptile and amphibian fauna of New Guinea remains unknown to science (Allison 1993). The vast diversity of biological life on New Guinea is a result of the island's diverse topography, extensive range of habitat types, and complex geological history. With elevations ranging from sea level to over 5000 m, the varied habitat zones, packed into an area one-tenth the size of the United States, include relictual tropical glaciers, alpine grasslands, montane moss forests, dense lowland rainforests, sago palm swamps, and eucalypt savannas.

The lowland rainforest on the north coast of Papua New Guinea has been severely impacted by logging (Beehler 1993). One of the few areas of lowland rainforest set aside for conservation and scientific study is the Kau Wildlife Area (KWA: 05°09'S, 145°46'E) near the provincial capital of Madang, Madang Province. The KWA is community owned and managed by the Didipa Clan of Kau and Baitabag Villages. The 800-ha KWA reserve is part of the extensive and broadly continuous Northern New Guinea lowland ecoregion that is made up of lowland, freshwater, and peat swamp forests. The lowland forests and freshwater swamps from this ecoregion contain diverse habitats, including lowland and hill forest, grass swamps, swamp forests, savannas, and woodlands (Conn 1995; Gressitt 1982; Henty 1981; Womersley 1978). The KWA, between 20–70 m in elevation, includes primary, successional, and riparian lowland broadleaf-evergreen forest. As many as 155 species of trees have been identified within a 1-ha plot of primary forest in the KWA (Bonaccorso et al. 2002). Dense stands of sago palm (*Metroxylon sagu*) are found in the low wet areas along the Kau and Biges Rivers. Many areas of the KWA have historically been subjected to traditional shifting fruit and vegetable gardens and many old abandoned garden areas surround the reserve. The climate of this region is wet tropical forest and in nearby Nagada Harbor annual precipitation averaged 3460 mm from 1994–96. The area is typified by distinct wet and dry seasons with less than 100 mm of monthly precipitation from June through August (Bonaccorso et al. 2002).

The northern region of New Guinea is a very active tectonic area with a complex geologic history. Over the last 40 million years interplate impact resulted in considerable uplift and volcanism and importantly the accretion of at least 32 tectonostratigraphic terranes along the northern leading edge of the island that have influenced the biodiversity of the region (Pigram and Davies 1987; Polhemus and Polhemus 1998).

To date there has been no comprehensive herpetofaunal reports from the KWA. Here I compile a list of terrestrial reptile species present in the KWA based on fieldwork over the past 14 years. The KWA terrestrial reptile fauna, exclusive of crocodylians and turtles, currently includes 25 lizards and 7 snakes representing 8 families and 21 genera (Table 1). A similar compilation is underway for the amphibians of the region (S. Richards, pers. comm.). Specific specimen and locality information as well as associated tissues can be accessed via a searchable database of the LSU Museum of Natural Science reptile and amphibian collection (http://www.lsu.edu/museum).

Species Richness, Taxonomy and Species-complex Groups

There are a large number of species complexes in the diverse New Guinea reptile fauna, especially among the scincid lizards. In addition to species complexes, many currently recognized species likely represent more than one taxon. Species richness, therefore, is likely much greater than is currently recognized. Below I comment on and address some of the taxonomic impediments to understanding the KWA terrestrial reptile fauna.

The agamid genus *Hypsilurus* is a poorly understood group. The taxonomy of the genus has been muddled by inadequate original descriptions, misidentified museum specimens, and the fact that the last comprehensive work on this group is 90 years old (de Rooij 1915). In particular, the geographic distribution and specific-level variation for virtually all species of *Hypsilurus* is not well understood. A recent comprehensive review of all type material has provided a much needed taxonomic summary and clarification (Manthey and Denzer 2006). Manthey and Denzer recognize 14 species of *Hypsilurus* acknowledging that this diversity is undoubtedly an underestimate (Manthey and Denzer 2006; Moody 1980). There are two species of *Hypsilurus* in the KWA: *H. modestus* and *H. papuensis*. *Hypsilurus modestus* is a relatively common small-bodied (maximum SVL = 107 mm) *Hypsilurus* with a broad range throughout the Papuan region (New Guinea and nearby associated islands), whereas *H. papuensis* is large bodied (maximum SVL = 190 mm) and uncommon with a poorly identified distribution throughout the Papuan region.

The gekkonid genus *Nactus* includes the widespread *Nactus pelagicus* complex that undoubtedly consists of several distinct species, the identification of which has been hindered by morphological conservatism and lack of adequate study. Based on morphological data, Zug and Moon (1995) determined the distribution of the asexual *N. pelagicus*, which includes Micronesia, southern Vanuatu (Erromango and Tanna Islands), New Caledonia, and eastward to Melanesia and Polynesia. *Nactus multicarinatus*, a bisexual species, has a range from the southern Solomon Islands and Vanuatu (excluding the islands of Tanna and Erromango) (Zug and Moon 1995). Donnellan and Moritz (1995) identified two highly differentiated populations of the *Nactus pelagicus* complex in Madang Province, Papua New Guinea based on allozymes. One of these Madang populations showed no fixed differences

TABLE 1. Checklist of the terrestrial reptile fauna of Kau Wildlife Area, Papua New Guinea. I refer to a species as 'Common' if it is typically encountered in an appropriate 8-h search period. Species listed as 'Uncommon' are encountered infrequently in the KWA and typically require more than a single day/night search of 8 h to locate.

Species	Comments & Literature
Lizards	
Agamidae	
Hypsilurus modestus	Common (Manthey and Denzer 2006; Moody 1980)
Hypsilurus papuensis	Uncommon (Manthey and Denzer 2006; Moody 1980)
Gekkonidae	
Nactus multicarinatus	Common (Donnellan and Moritz 1995; Moritz 1987; Zug and Moon 1995)
Cyrtodactylus sp.	Uncommon (Brown and Parker 1973)
Gekko vittatus	Common (de Rooij 1915)
Gehyra sp.	Uncommon (Beckon 1992; Chrapliwy et al. 1961; King 1984; King and Horner 1989)
Hemidactylus frenatus	Common (Mortiz et al. 1993)
Lepidodactylus lugubris	Common (Mortiz et al. 1993)
Scincidae	
Carlia mysi	Common (Zug [2004] revised the *Carlia fusca* complex)
Emoia caeruleocauda	Common (Brown 1991)
Emoia longicauda	Uncommon (Brown 1991)
Emoia jakati	Common (Brown 1991)
Emoia kordoana	Uncommon (Brown 1991)
Lamprolepis smaragdina	Common (Greer 1970)
Lipinia noctua	Uncommon (Austin 1998; Zweifel 1979)
Lobulia brongersmai	Uncommon (Allison and Greer 1986; Zweifel 1972)
Prasinohaema virens	Uncommon (Mys 1988)
Sphenomorphus jobiensis	Common (Donnellan and Aplin 1989)
Sphenomorphus mulleri	Uncommon (de Rooij 1915)
Sphenomorphus simus	Common (formally *S. stickli*, Shea and Greer 1999)
Sphenomorphus solomonis	Common (de Rooij 1915)
Sphenomorphus derooyae	Uncommon (de Rooij 1915)
Triblonotus gracilis	Uncommon (Cogger 1972; Zweifel 1966)
Varanidae	
Varanus indicus	Common (low density) (Böhme 2003)
Varanus prasinus	Uncommon (low density) (Böhme 2003; Sprackland 1991)
Snakes	
Boidae	
Candoia aspera	Common, the most common terrestrial snake found in Kau (Austin 2000)
Candoia carinata	Uncommon (Austin 2000)
Pythonidae	
Morelia viridis	Uncommon (low density) (Rawlings and Donnellan 2003)
Colubridae	
Boiga irregularis	Uncommon (O'Shea 1996)
Stegonotus modestus	Uncommon (O'Shea 1996)
Stegonotus parvus	Uncommon (O'Shea 1996)
Elapidae	
Micropechis ikaheka	Uncommon (O'Shea 1996)

with the Solomon and northern Vanuatu bisexual *Nactus multicarinatus* populations and thus this name should apply to one of the two Madang populations (Zug and Moon 1995). The contact zone, if there is one, between the two genetically distinct Madang populations has not been identified and it is possible that both populations, likely corresponding to two distinct species, occur

in the KWA.

The gekkonid genus *Gehyra* in New Guinea consists of several species, the taxonomy of which is in need of revision (King 1984; King and Horner 1989). The geographic distribution and specific-level variation for virtually all species of New Guinea *Gehyra* is not well understood and many collections have misidentified taxa.

The scincid *Sphenomorphus jobiensis* complex was first identified from allozyme data and, to a limited extent, morphology, but these data were not used to delineate species boundaries (Donnellan and Aplin 1989). DNA sequence data (Austin, unpubl. data) confirm the apparent specific-level differentiation found by Donnellan and Aplin (1989). In addition to the *S. jobiensis* complex, there are many other complexes that involve multiple cryptic species. These include the complexes within the genus *Sphenomorphus* (*S. derooyae*, *S. leptofasciatus*, *S. mulleri*, *S. pratti*, and *S. solomonis*, complexes). *Sphenomorphus derooyae* is likely a complex of several species with many names available for different populations (*cranei*, *derooyae*, *maindroni*, and *wolfi*; G. Shea, pers. comm.). In addition, other problematic groups include the *Lipinia noctua* complex (Austin 1999a,b), *Papuascincus stanleyanus* complex, *Emoia longicauda* complex, and *Carlia fusca* complex (Zug 2004). Only the latter complex has been adequately studied with 14 morphologically distinct species identified and taxonomically delineating in the New Guinea region (Zug 2004). *Carlia mysi*, with a broad range across the northeast coast of New Guinea and the Bismarck Archipelago, is the only *Carlia* species recorded from the KWA.

Unconfirmed Species that Possibly are Present in the KWA

Species not collected or visually confirmed, but likely present in the KWA, include (1) members of the *Cryptoblepharus boutonii* complex, which includes up to 36 'forms' (Mertens 1931) many of which are likely distinct species. Although not seen in the KWA, forest populations of *Cryptoblepharus* are often more secretive than coastal intertidal populations. (2) The genus *Emoia* includes approximately 42 species from New Guinea and associated archipelagos. The diversity and morphological conservatism in New Guinea *Emoia* has led to considerable confusion concerning the identification and taxonomy of this group. The genus *Emoia*, comprising 72 species, was revised by Brown (1991). This much-needed revision helped, but did not eliminate taxonomic obstacles for this large genus. In addition to the four *Emoia* recorded from KWA, six species of *Emoia* that occur in adjacent areas may be present in KWA. These include *Emoia battersbyi*, *E. cyanogaster*, *E. loveridgei*, *E. pallidiceps mehelyi*, E. *popei*, and *E. veracunda* (Brown 1991). (3) Seven other skinks with widespread yet patchy distributions along the north coast of New Guinea may be present in the KWA. These include *Eugongylus rufescens*, *Lipinia longiceps*, *L. pulchra*, *Sphenomorphus minutus*, *S. neuhaussi*, *S. pratti*, and *Tiliqua gigas* (Austin 1995, 1998; Mys 1988). *Sphenomorphus minutus*, although currently included in the *Sphenomorphus* group of Lygosomine skinks (Greer 1974, 1989; Hutchinson 1993), is actually a member of the *Eugongylus* group (Austin, unpubl. data). (4) Three pythons (*Apodora papuana*, *Leiopython albertisii*, and *Morelia amethistina*), while not recorded from the KWA, are likely present as they have been collected in nearby forested and human-disturbed areas adjacent to the KWA. (5) *Dendrolaphis calligasta* and *D. punctulatus* have both been recorded from Madang Province and likely occur in the KWA (O'Shea 1996). (6) *Acanthophis* spp. have been recorded from Madang Province, but are typically found in open grassland not heavily forested regions like the KWA (O'Shea 1996). Various specific epithets have been given to the several geographic races of New Guinea populations of *Acanthophis*, yet authors differ in their assignment and the taxonomy of this group needs examination (McDowell 1984; Storr 1981; Wüster et al. 2005).

Acknowledgments.—I thank the people of KWA for the privilege to conduct fieldwork on their land. I also thank I. Bigilale and F. Bonaccorso from the PNG National Museum for their support of my field efforts. B. Roy, V. Kula, and B. Wilmot from the PNG Department of Environment and Conservation, and J. Robins from the PNG National Research Institute provided assistance with research visas and export permits. This research was funded in part by the National Science Foundation (DEB 0445213) and a Louisiana State University Faculty Research grant. I also thank A. Bauer and L. Grismer for helpful comments on an earlier version of this manuscript.

Forensic Implications of Dorsal Scale Row Counts on Puff-faced Water Snakes (Colubridae: Homalopsinae: *Homalopsis buccata*)

BARRY W. BAKER
U.S. National Fish & Wildlife Forensics Laboratory
1490 East Main Street, Ashland, Oregon 97520-1310, USA
e-mail: barry_baker@fws.gov

"The Dorsals. These scales are perhaps the most useful of all guides in enabling us to differentiate between species and genera, but authors have not availed themselves of their full value." [Wall 1902:338]

Wildlife, including live animals, parts, or products manufactured from wildlife, must be properly declared to species of origin when imported into, or exported from, the United States. Forensic scientists at the U.S. National Fish and Wildlife Forensics Laboratory (U.S. Fish & Wildlife Service) assist law enforcement agencies in identifying animals and animal products in cases where suspected wildlife violations have occurred (Goddard and Espinoza 2000). While the Laboratory does not initiate or lead such investigations, it provides forensic support in a broad range of areas including species identification (morphological and molecular), cause of death examination, forensic chemistry, digital evidence analysis (computer, audio, video and photography), fingerprint, firearm, and tool mark analysis, and crime scene investigation.

Rigorous methods for identifying species in the wildlife trade are critical to law enforcement efforts to enforce wildlife legislation and international treaties (e.g., CITES), and to facilitate the legal trade in wildlife. Here I review published accounts of dorsal scale row counts in the puffed-faced water snake (*Homalopsis buccata*) and their forensic implications for identifying this species in the wildlife trade. While this species is not listed on CITES, enforcement personnel are often called upon to identify this snake to facilitate the legal trade in wildlife. I show that published scale row counts vary considerably and summarize these for wildlife law enforcement purposes.

The puffed-faced water snake is exploited extensively in the wildlife trade, where its skin is used to manufacture leather products (Stuart et al. 2000). Zhou and Jiang (2004) reported that between 1991 and 2001 alone, 1,448,134 skins of this species were imported into China for the leather trade. Stuart (2004) reported numerous live specimens in reptile trade shops in Vietnam. Jenkins and Broad (1994) list *H. buccata* as the third most common reptile skin imported into the U.S. during the years 1984–1990, consisting of 1,645,448 skins.

This species is distributed through southeast Asia, including parts of Bangladesh, India, Nepal, Myanmar, Thailand, Cambodia, Malaysia, Indonesia, Laos, Singapore, and Vietnam (Al-Murani 1990; David and Vogel 1996). Various other common names have been applied to *H. buccata*, including the Masked Water Snake (Murphy et al. 1998), the Dog-faced Water Snake (Campden-Main 1984) [this name is more commonly applied to *Cerberus rynchops*], and the Asian False Water Boa (Franke and Telecky 2001). Reviews of the general morphology, ecology, and phylogenetics of *H. buccata* (in addition to those in Table 1) are provided by Berry and Lim (1967), Murphy and Voris (1994), Stuart et al. (2000), Voris and Murphy (2002), and Voris et al. (2002). Two subspecies (*H. b. buccata* and *H. buccata nigroventralis*) have been described (Deuve 1970), though few researchers appear to be aware of these designations.

Although morphological descriptions of this snake are provided by many researchers, there is marked variability in published ranges for dorsal scale row counts (Table 1). This has the potential to lead to confusion in law enforcement efforts to monitor trade in this species, and has implications for the concept of "scientific certainty" (Bird 2001) in identifying this snake in a forensic context. Snake skins in the leather trade are often dyed, obscuring any original body coloration or banding patterns. Identification, therefore, may rely on scale shape, keeled vs. smooth scale morphology, and dorsal scale row counts to determine if a leather item is consistent with the species it was declared to be.

One of the most widely available texts to assist law enforcement personnel in their identification of snake skins in the leather trade is Mahnert (1981). The entry for *H. buccata* in this volume lists the number of dorsal scale rows in this species as 43–47, citing Taylor (1965), a reference well known and extensively used by herpetologists. In this example, a dyed snake skin with a dorsal scale row count of 35 at mid-body could be interpreted to be inconsistent with *H. buccata,* given the fact that Taylor reports the range for this species as 43–47. However, further review of the literature shows marked variability in published scale row counts for this species (Table 1).

Taylor (1965) noted that "The number of scalerows on the body is an important character and the number may vary at different points on the body." His description is somewhat confusing though, in that he stated "…number of scalerows variable, 37–47" (Taylor 1965:921), while at the same time noting "Variation in scalerows at the middle of the body is 43–47, the usual number being 45" (Taylor 1965:922). Though not explicitly stated, Taylor's report of 37–47 scale rows presumably refers to variability across the entire body length of an individual.

Even more confusing is Smith's (1943) description. In his general description of the monotypic genus *Homalopsis*, he describes the scales as "…in 39 to 47 rows" (Smith 1943:390). However, his more detailed entry under the species name *Homalopsis buccata* lists "Scales in 43–47, usually 45, rows" (Smith 1943:43–47). In neither description did he note body location, a critical variable in interpreting scale counts.

Gyi (1970), in his extensive and often cited revision of the subfamily Homalopsinae, reported dorsal scale rows in *H. buccata* as "37–41 at midbody." However, a closer review of his raw data (Table 12, p. 141) shows a range of 35–47 scale rows at midbody. In his key to the genera of the Homalopsinae, he describes *Homalopsis* with "dorsal scales in 39–47 rows" (Gyi 1970:61). The origin of this significant discrepancy by Gyi in these three instances is not clear.

The earliest report of scale row counts for *H. buccata* uncovered in my review is Günther (1864), who described the scales as ranging from 37–47 rows. The two most recent references (Fuchs and Fuchs 2003; Stuebing and Inger 1999) also produced the widest ranges (Table 1). While the notation of Fuchs and Fuchs (2003:229) (see Table 1) is not elaborated, the inference is that scales typically occur in 43–47 rows, but are known to range from

TABLE 1. Published ranges for dorsal scale row counts in *Homalopsis buccata*.

37–49 rows. This count of 49 scale rows is the highest of any mid-body dorsal rows reported for this species. The lowest count at mid-body is reported by Stuebing and Inger (1999), who list a range of 32–48. Interestingly, they do not elaborate on the low end of their range or compare it to previous accounts, which are generally higher. The combined ranges of Fuchs and Fuchs (2003) and Stuebing and Inger (1999) result in a published dorsal scale row count in *H. buccata* of 32–49 scales at midbody. This range is significantly different from most accounts in Table 1, especially that reported by Mahnert (1981), a reference used by many of those responsible for monitoring the wildlife trade. Based on this review, it appears that the entire range of dorsal scale counts of 32–49 at mid-body should be considered consistent with *H. buccata* by wildlife law enforcement personnel.

This review reiterates that both accurate and precise morphological descriptions are critical not only to taxonomic research, but to forensic efforts and the conservation of species. It is likely that many herpetologists are unaware that their research, even basic descriptions, may be used in a forensic and legal context. In addition, enforcement personnel must be made aware that published morphological descriptions may refer only to a limited range of variability within a species. It appears that Taylor's (1965) data have been used inappropriately by some as a diagnosis for the species from its entire range. The wide geographic range of *Homalopsis buccata* and additional research has revealed further variability in dorsal scale rows in this species. Additional documentation of scale count variability in *H. buccata* outside the range summarized here is also warranted, as are similar reviews of other snake species in the wildlife trade.

Acknowledgments.—I thank Rick Brooks (USFWS), who prompted this review, and B. Stuart, B. Weissgold, R.N. Reed, B. Yates, and P. Trail for editorial comments.

For decades, herpetologists have been striving to reveal the foraging ecology of snakes (Arnold 1993). In spite of considerable effort to collect snake dietary information, the diets of many species remain unknown. The diets of snail-eating snakes are among the least well known. Adaptations for extracting snails from their shells have arisen independently in at least three subfamilies of colubrid snakes: Pareatinae, Natricinae, and Dipsadinae (Gotz 2002; Rossman and Myer 1990; Sazima 1989). When feeding on a large snail, the snake inserts its mandibles into the snail's aperture, and moves each mandible forward and back to extract the body of the snail. Although snails have been confirmed as the primary prey of these snake species via feeding observations of captives and from gut content analysis of wild snakes, the natural prey have rarely been identified to species. This is because molluscs that are swallowed without shells were thought to leave no diagnostic remnants in the guts or feces of snakes (Peters 1960). The only available report in which snails eaten by wild snakes were identified to species is that of Judd (1954). He identified prey on the basis of shells, jaws, and radulae of snails found in the stomachs, intestines, and feces of several individuals of *Storeria dekayi* in Ontario, but he did not describe the characters on which he based his identification of species.

All species of the pareatine genus *Pareas* occur in Southeast Asia and are believed to feed exclusively on terrestrial snails and slugs (Greene 1997). This diet was confirmed by providing non-native terrestrial snails to captive snakes of the genus *Pareas* (Hirata and Ota 1993; Otani 1983) but the species identity of native prey species has not been determined. Here we present the first record of prey species identified from the feces of *Pareas iwasakii*, determined by scanning electron microscopy (SEM). We propose that our method may be applicable to the identification of prey in other snail-eating snakes.

We surveyed literature on the terrestrial molluscan fauna of Iriomote and Ishigaki Islands (Azuma 1995; Habe and Chinen 1974) to determine which species of large snails (shell diameters > 10 mm) and slugs were potential prey for wild *P. iwasakii*,. To examine preferences for these species of snails, a male *P. iwasakii* (SVL = 440 mm, captured on Iriomote Island on 19 May 2004) was maintained in a cage with snails collected from Iriomote Island. Snails that remained alive in the cage with the snake for more than one month were considered not to be preferred species, and thus were excluded from the reference species to which fecal samples were compared.

Prior to its use in the preference experiment, and before it had fed in captivity, the same male *P. iwasakii* excreted feces on 21, 22, and 24 May. These three fecal samples were preserved in 99% ethanol. Microscopic examination of the earliest sample revealed a jaw and several fragments of a radula that were seemingly derived from a single snail. The radula and jaw are the hardest parts of a snail's body, except for the shell, and are not digestible because they are composed of chitin. The minute radular teeth and jaw have been used as characters for the classification of terrestrial snails (Solem 1978). We examined the radula (using SEM) and the jaw (using a binocular microscope), and compared them with reference specimens prepared from terrestrial snails from Iriomote Island that had been selected as described above.

The literature survey revealed that the large terrestrial molluscs of Iriomote and Ishigaki include 13 species of snails in 9 genera and no native slugs (Table 1). Of the snails, *Pareas iwasakii* ate only 7 species (3 genera; *Satsuma, Aegista*, and *Acusta*). *Bekkochlamys masakii* and *Videna carthcartae* were not eaten by *P. iwasakii*, but the early deaths of these snails precluded confirmation of their status as prey species.

SEM could not reveal the formula of the radula contained in the feces because the marginal teeth were damaged; thus, the number of transverse radular teeth could not be counted. Nonetheless, the

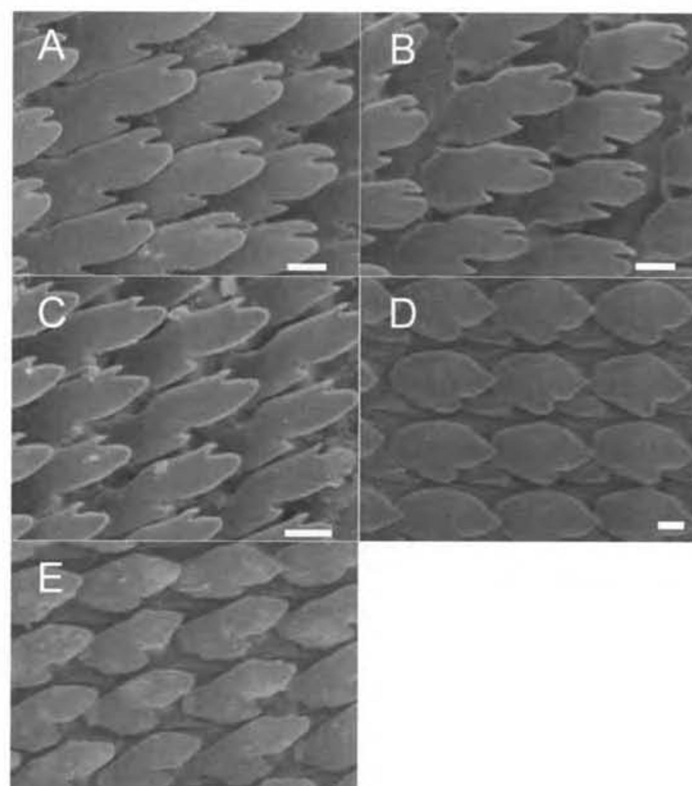

FIG. 1. The SEM photographs of the radulae of terrestrial snails. (A) The radula recovered from feces of a wild-captured *Pareas iwasakii*. (B) The radula of *Satsuma caliginosa*. (C) The radula of *S. yaeyamensis*. (D) The radula of *Acusta tourannensis*. (E). The radula of *Aegista mackensii*. Scale bars = 10 μm.

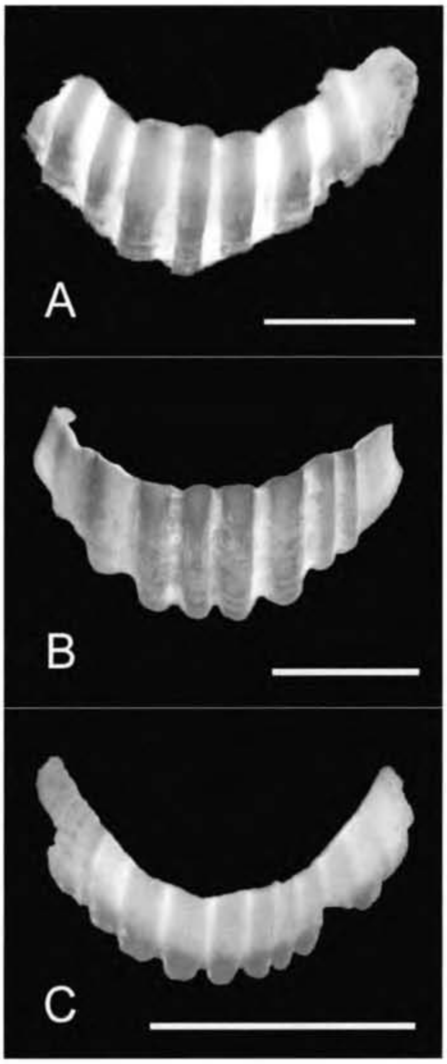

FIG. 2. Binocular photographs of the jaws of terrestrial snails. (A) The jaw recovered from feces of *Pareas iwasakii*. (B) The jaw of *Satsuma caliginosa*. (C) The jaw of *S. yaeyamensis*. Scale bars = 1 mm.

radula was conclusively identified as belonging to an individual of the genus *Satsuma* based on the diagnostic deeply notched trident structure of the radular tooth (Figs. 1A–E). Although it was difficult to distinguish between the radular teeth of *S. caliginosa* and *S. yaeyamensis* (Figs. 1B, C), the two congeners could be distinguished by the size and microstructure of the jaw (Figs. 2B, C). Consequently, the prey item was identified as *S. caliginosa* (Figs. 1A, B, 2A, B). Furthermore, comparison of the recovered jaw with those of *S. caliginosa* of various sizes suggests that the prey item was an immature individual.

Food habits of snakes are generally investigated by examination of gut contents of preserved specimens or by forced regurgitation of stomach contents from live specimens. Because both forced regurgitation of soft bodied prey and identification of extracted or well-digested snails are difficult, most herpetologists have thought that it is impractical or impossible to identify molluscan prey eaten by snakes (Cobb 2004; Kofron 1982; Peters 1960). Conceivably, the stomach contents of a snake that had eaten a snail just before capture might include the undigested reproductive organ, which is an important diagnostic feature. However, the diagnostic feature of a reproductive organ would rarely be recovered from the stomach because any soft tissues of a snail would be rapidly digested. Moreover, not all stomach contents may be collected by forced regurgitation. *P. iwasakii* is a vulnerable species (Ota 2000), and Pareatinae occur only in the tropical forests of southeastern Asia, which are rapidly being modified by human activities (Laportaferreira and Salomao 2004). Thus, the identification of prey species of snail-eating snakes based upon fecal analysis is strongly recommended as a non-invasive method.

TABLE 1. The large-shelled native inland snails of Iriomote and Ishigaki Islands (diameter > 10 mm), and feeding preference of *Pareas iwasakii* for these snails. D: diameter of snails according to Azuma (1995), Y: eaten by the snake, N: not eaten by the snake.

Species	D (mm)	Feeding result
Acusta tourannensis	16.0	Y
Aegista mackensii	42.5	Y
Ae. vermis	28.5	Y
Ae. caerulea	23.0	Y
Ae. osbeckii	20.0	Y
Bekkochlamys masakii	15.0	N?
Cyclophorus turgidus radians	26.5	N
Cyclotus taivanus peraffinis	15.0	N
Leptopoma nitidum	17.0	N
Luchuena eucharista	11.5	N
Satsuma caliginosa	37.0	Y
S. yaeyamensis	31.0	Y
Videna carthcartae	16.5	N?

To identify prey from visually unrecognizable remains in predator diets, a polymerase chain reaction (PCR)-based molecular method may provide a powerful tool (Symondson 2002). However, molecular methods have three disadvantages in comparison with our method. First, molecular methods require more expensive equipment and reagents than does our method. Second, PCR is not always successful because of the possible deterioration of DNA during digestion. Third, molecular methods may not reveal the number and size of identified prey. In the present paper, the number of prey consumed was confirmed to be one individual. Although the size of the prey was not definitively determined, examination of reference specimens enabled us to estimate the size of the consumed snail. On the other hand, a disadvantage of our method is that it requires preparation of reference samples of radulae of local snails. However, molecular methods also require the preparation of reference DNA sequences, although sequences from closely related species in DNA databases would also yield useful results. We suggest that the identification of radulae and jaws from feces is a more useful method for identifying the prey of snail- and slug-eating snakes than is identification from DNA contained in feces or identification from stomach contents obtained by sacrificing snakes. Furthermore, the stomach contents of road-killed snakes or preserved snake specimens in museums may be available.

We offer the following suggestions to those preparing samples for the identification of molluscan prey based on radulae retained in stomach or fecal contents of snakes. It is best to clean the radu-

lae in vials with very little water, using ultrasonic cleaning equipment for a few minutes. Excessive treatment sometimes disintegrated the fragile radulae of snails collected from feces. Holznagel (1998) recommended an enzymatic cleaning method for radulae that could be adapted for use with fecal samples. Because it is difficult to distinguish the dorsal from the ventral side of a radula prior to SEM, the radulae should be divided into two or more pieces and the resulting samples prepared so that both sides will be visible during SEM observation.

Our captive observations suggest that *P. iwasakii* has preferences for specific groups of land snails. Otani (1983) reported that *P. iwasakii* refused to eat certain snails including Cyclophoracea (*Leptopoma nitidum*, *Cyclophorus turgidus radians*, and *Cyclotus taivanus peraffinis*). Because of the early accidental death of *Bekkochlamys masakii* during our experiment, it is unclear whether *P. iwasakii* will consume that species.

The identified prey, *S. caliginosa*, is one of the most abundant, rather arboreal snails in the habitat of *P. iwasakii* at night (M. Hoso, unpubl.). The snake is assumed to be an arboreal, forest-dependent species (Toyama 1996), and several species of *Pareas* are able to extract snails deftly and eat soft tissues while perched on a branch in captivity (Gotz 2002; M. Hoso, pers. obs.). These observations suggest that *P. iwasakii* forages above the ground, so we suppose that the snake encounters *S. caliginosa* frequently.

Acknowledgments.—We thank S. Kobayshi, M. Saigusa, and H. Yano for providing facilities in the field, and C. Matsumoto and H. Ota for providing useful information. We also thank Y. Takami and E. Takahashi for teaching us the use of SEM. We thank A. Mori and A. Savitzky for valuable comments on the manuscript. We are indebted to A. Iwata for supporting our research. This work was partly supported by grants-in-aid from the Science Research on Priority Areas (1408703) and the Grant for the Biodiversity Research of the 21st Century COE (A14) of the Japan Ministry of Education, Culture, Sports, Science and Technology to M. Hori. This paper is a contribution from Iriomote Station, University of the Ryukyus.

Advances in molecular technology have led to the discovery of a number of lizard species living in stable family groups. These social lizards provide an opportunity to test current hypotheses about the evolution and maintenance of vertebrate social systems developed using endothermic models (i.e., birds and mammals). As such, social lizards have increasingly been the focus of intense research, in particular studies within the Australian *Egernia* Group lineage of skinks.

The scincid genus *Egernia* comprises 32 species of medium to large-sized viviparous skinks and is endemic to Australia (Chapple 2003). Recently, much interest has been generated in this group due to the realization that complex social systems and monogamy are widespread within the genus, with reports on 26 of the 32 species suggesting social structures of varying complexity, ranging from predominately solitary through to large social aggregations in excess of 30 individuals (reviewed in Chapple 2003). Long-term behavioral and genetic studies on four species have shown that these large aggregations are stable between years and consist of closely related individuals (Chapple 2003). In addition, *E. cunninghami*, *E. saxatilis* and *E. stokesii* have been shown to exhibit long-term social and genetic monogamy, with *E. cunninghami* and *E. stokesii* exhibiting strong inbreeding avoidance (Gardner et al. 2001, 2002; O'Connor and Shine 2003; Stow et al. 2001; Stow and Sunnucks 2004a,b). Such behavioral traits are extremely rare in lizards (Bull 2000), therefore the genus provides a unique opportunity to examine the evolution of complex sociality within squamate reptiles and test existing hypotheses about the evolution of vertebrate sociality (Chapple 2003).

Several factors have enabled *Egernia* to be utilized as a 'model' system for examining the evolution of sociality and monogamy in lizards. First, most species are large, long-lived and exhibit a strong attachment to a home site (e.g., rock crevice, burrow, log) and therefore are well-suited to long-term behavioral and genetic studies (Chapple 2003). Second, a large number of microsatellite primers have been developed for *E. stokesii* (Gardner et al. 1999; 11 EST primers), *E. cunninghami* (Stow 2002; 5 Ecu primers) and the closely related *Tiliqua rugosa* (Cooper et al. 1997; 6 Tr primers). However, what has facilitated the research to date is a high degree of successful cross-species PCR amplification of microsatellite loci within the lineage using the same primer pairs. These primers have now been utilized for examining aspects of sociality and mating systems in *E. stokesii* (Gardner et al. 2001, 2002), *E. saxatilis* (O'Connor and Shine 2003), *E. cunninghami* (Stow et al. 2001; Stow and Sunnucks 2004a,b), *E. striolata* (Bonnett 1999; Bull et al. 2001), *E. whitii* (Chapple and Keogh 2006) and *E. frerei* (Fuller et al. 2005).

Because this is a burgeoning and active area of research, similar studies are expected to be conducted for most other *Egernia* species (Chapple 2003). However, at present there is a lack of detailed information on the cross-species amplification of available *Egernia* microsatellite primers (especially for those that were problematic for some species). Microsatellite markers are costly and time intensive to develop and successful cross-species amplification can represent a substantial reduction in cost and time. Detailed information on the potential utility of each microsatellite locus would aid in selecting primers for particular *Egernia* species, saving time and money. Here we report the cross-species application of the available microsatellite primers in five *Egernia* species. These species represent four of the six species groupings within the genus: *E. cunninghami* and *E. stokesii* (*cunninghami* group, 4 species), *E. saxatilis* (*striolata* group, 9 species), *E. whitii* (*whitii* group, 12 species) and *E. frerei* (*major* group, 4 species). Since the remaining two species groups comprise a total of three species (*E. kingii* group, 1 species; *E. luctuosa* group, 2 species), the four species groups that we examine contain 29 of the 32 species in the genus and therefore should provide valuable information for future researchers. In order to supplement our detailed analysis of five species we provide a brief summary of the results from published studies that have used microsatellites in *Egernia* species.

The PCR conditions used for each species are contained within the original published studies and therefore we only provide relevant information that has not been published elsewhere. For *E. stokesii* details regarding PCR conditions and parameters are contained in Cooper et al. (1997) and Gardner et al. (1999, 2000, 2001, 2002), with the conditions for the Ecu primers as detailed in Stow (2002). For *E. cunninghami* this information is provided in Stow et al. (2001), Stow (2002), and Stow and Sunnucks (2004a, b),

TABLE 1. Cross-amplification of the available microsatellite primers in the *Egernia*, *Tiliqua* and *Cyclodomorphus* species tested to date. P = polymorphic; M = monomorphic; U = unsuccessful amplification; ? = some degree of amplification (see Table 2 for further detail). Species codes as follows: EC = *E. cunninghami*, EF = *E. frerei*, EI = *E. inornata*, ESa = *E. saxatilis*, ESto = *E. stokesii*, EStr = *E. striolata*, EW = *E. whitii*, TA = *T. adelaidensis*, TR = *T. rugosa*, TS = *T. scincoides*, CB = *C. branchialis*, CC = *C. casuarinae*, CG = *C. gerrardii*.

while those for *E. frerei* are contained in Cooper et al. (1997), Gardner et al. (1999, 2000), Stow (2002), and Fuller et al. (2005).

Information relating to the cross-amplification in *E. whitii* is contained in Chapple and Keogh (2005, in press). In this species PCR was performed in a 20 µl volume reaction, containing approximately 100 ng of template DNA, 2.5 pmol of the M13(-21) tailed sequence-specific forward primer, 10 pmol of the sequence-specific reverse primer, 10 pmol of a fluorescent dye-labelled M13(-21) universal primer (either 6-FAM, NED or PET; Applied Biosystems), 2 µl 10x PCR Buffer, 2 µl 10x Enhancer Solution (Gibco BRI Life Technologies), 3 mM $MgSO_4$, 2 mM dNTPs and 0.2 units of Platinum *Taq* DNA polymerase (Gibco BRI Life Technologies). A 'stepping down' PCR program was used to amplify each locus. Reactions were initially denatured at 94°C for 5 min, followed by an annealing step at 70°C for 15 sec and extension at 72°C for 1.5 min. This was followed by a further round of denaturation at 94°C for 30 sec, annealing at 70°C for 15 sec and extension at 72°C for 1.5 min. The annealing temperature was then dropped by 5°C in the next two rounds of cycling. This 'stepping down' in annealing temperature was repeated until a final annealing temperature of 35°C was reached. The next 50 cycles then were performed with this annealing temperature. A final extension step at 72°C was done for 7 min.

Details concerning the amplification of the loci in *E. saxatilis* are contained in Cooper et al. (1997), Gardner et al. (1999), and O'Connor and Shine (2003). PCR was performed in a 10 µl volume reaction, containing 5 µl of template DNA, 1x PCR reaction buffer, 1.5 mM $MgCl_2$, 0.1 mM dNTPS, 400 nM of each primer, and 0.25 units of *Taq* DNA polymerase (all Sigma reagents). The PCR parameters for the Ecu primers followed Stow (2002). The PCR program for EST2, EST12 and Tr4.11 involved an initial denaturing step of 94°C for 3 min, followed by 35 cycles of 94°C for 30 sec, 55°C for 30 sec, and 72°C for 30 sec, followed by a final extension step at 72°C for 10 min. The parameters for EST1 and Tr5.21 were similar except that the 35 cycles were substituted with one cycle with an annealing temperature of 55°C, followed by single cycles at 53°C, 51°C, and 49°C, with a further 30 cycles at 47°C. For Tr5.20, these cycles were replaced by 7 cycles at each of the following annealing temperatures: 55°C, 53°C, 51°C, and 49°C. For EST8 and EST9 the 35 cycles were replaced by annealing temperatures of 55°C (2 cycles), 53°C (2 cycles), 51°C (2 cycles), 49°C (2 cycles) and 47°C (20 cycles).

Within *Egernia* there are eight primer pairs that appear to perform well across all lineages (Table 1). The most successfully used loci are EST1, EST2, EST12, Tr5.20 and Tr5.21 with promising preliminary results from the recently developed Ecu1, Ecu2 and Ecu5 primers. The *Egernia* range of primers is highly polymorphic and extremely informative (Table 2). Tr4.11 however, ap-

TABLE 2. Cross-amplification of the available microsatellite primers in five *Egernia* species. Several loci were not trialled in each of the species: *E. cunninghami* (Tr3.8, EST14, EST16), *E. saxatilis* (Tr3.2, Tr3.8, Tr4.6, EST3-4, EST6, EST14-16), *E. whitii* (Tr3.8, Tr4.6, EST6, EST14-16), *E. frerei* (Tr3.2, Tr3.8, EST3, EST6, EST14-16, Ecu2, Ecu4-5) and *E. stokesii* (Ecu3). N = number of individuals trialled; NA = number of alleles; Ho = Observed heterozygosity; He = Expected heterozygosity; HWE P = *P*-value for Hardy-Weinberg equilibrium for each locus.

pears to be sex linked (females heterozygous) and Tr3.2 and EST12 appear to be directly linked (Table 2). Problems with short allele dominance and null alleles are present within the lineage but are not consistently related to a particular primer but rather the primer-species interaction (Table 2). Overall, the *Egernia* microsatellite loci are highly polymorphic and extremely informative for studies of sociality.

Acknowledgments.—DGC thanks Chris Hayes for assistance in the laboratory. Funding was provided to DGC by Australian Geographic, Australian Society of Herpetologists, ASIH Gaige Fund, Peter Rankin Trust Fund for Herpetology, Joyce W. Vickery Scientific Research Fund, Ecological Society of Australia and SSB Award for Graduate Student Research. Funding for the *E. frerei* research was provided by the Australian Research Council and a Program Grant from the Faculty of Science and Engineering, Flinders University. SF thanks staff from the Evolutionary Biology Unit of the South Australian Museum for helpful advice and discussion. DO'C thanks Kellie Palmer for assistance in the testing and optimization of the *E. saxatilis* primers. Funding was provided to DO'C by a Royal Zoological Society of New South Wales Ethel Mary Read grant and a Peter Rankin Trust Fund for Herpetology grant.

Innovative Techniques for Sampling Stream-inhabiting Salamanders

THOMAS M. LUHRING
and
CAMERON A. YOUNG
Savannah River Ecology Laboratory, Drawer E
Aiken, South Carolina 29803, USA
e-mail: tluhring@uga.edu
e-mail: young@srel.edu

Although salamanders are excellent indicators of environmental health, the ability to catch them efficiently without substantially disrupting their habitat is not always practical or even possible with current techniques. Ripping open logs and raking leaf packs onto shore (Bruce 1972) are examples of such practices that are disruptive but widely used by herpetologists who have no other means of efficient collection. Drift fences with pitfall traps are effective in catching animals moving within or between habitats but are time consuming and require an initial financial investment and constant upkeep to maintain functionality and prevent animal fatalities (Gibbons and Semlitsch 1981). One current alternative to drift fences is the use of coverboards (Grant et al. 1992), which require less maintenance and sampling effort than drift fences. However, coverboards do not integrate captures over a long time period and often result in a lower number of captures per trap (Grant et al. 1992).

The purpose of our study was to evaluate the effectiveness of a new trap design for sampling stream-inhabiting salamanders. The traps were designed to be non-destructive to the habitat while being economical and time efficient. The new trap, a combination of PVC pipe and coverboard (PC trap), was specifically designed to take advantage of the tendency of species in habitats near water to run toward the water when their cover is disturbed and then remain motionless amongst the detritus. The coverboard of PC traps was used to create a habitat for the salamanders that could be efficiently surveyed and replaced. The other "traps" (coverboards and sections of PVC pipe) were used as comparisons. We predicted that the PC trap would have a higher number of captures per trap than coverboards or sections of PVC used separately. Although the techniques tested are being referred to as "traps," they are designed to be "escapable" and thus able to be left in place unaltered and unchecked indefinitely without causing mortality to salamanders or non-target species.

The study site, a seep-fed spring that originated at the bottom of a gorge and terminated at a constructed pond, spanned approximately 365 m of mixed hardwood forest near the Fall Line in Richmond County, Georgia. Twenty arrays were placed at 12.4-m intervals along the spring's banks. An array consisted of one of each trap type placed in random order at 1.8-m intervals. Randomness was achieved by designating each trap with a number (PVC = 1, coverboard = 2 and PC = 3) and then using a random number table to select their order. Each interval was measured from the closest edge of each trap. All traps were 73 cm in length. Arrays were numbered from 1 to 20 starting at the beginning of the spring and each trap was labeled by array number and type. For example, type "A" (PVC), type "B" (coverboard), and type "C" (PC) in array 15 were labeled as "15A," "15B," and "15C," respectively. Arrays were checked, in order, from the downstream end (array 20) to the upstream end (array 1).

The PVC trap consisted of a 73 cm section of 18 cm polyvinyl chlorate (PVC) with holes drilled on each end for "stakes" (wire insulation supports) to anchor it into the spring bed. These were placed in the middle of the spring and were checked internally before being rolled over on each survey date. Coverboards were composed of a 73 cm × 73 cm section of 11-mm plywood. These were placed parallel to the spring with approximately 18 cm of the board overhanging the spring or in the spring to mimic the amount of overhang associated with the PC trap.

The novel trap, PC, was a "PVC-coverboard hybrid" made of two independent parts (Fig. 1). The first part of the PC trap was a section of 11 mm plywood identical to that of the coverboards. This was used in conjunction with a 73 cm section of lengthwise-halved 18 cm PVC. Wire screen (gutter guard) was cut to fit each end of the PVC halves and was attached to the pipe with six zip ties that were drawn through six small, evenly spaced holes on each end of the PVC. The halved PVC of PC traps were anchored with the same "stakes" as PVC traps. These halved pipes were anchored by pushing the "stakes" into the ground on the terrestrial side of the pipe and bending their ends to catch the lip of the pipe. The pipe halves of PC traps were placed inside the spring parallel to and touching the bank with their terrestrial edge as tightly fitting with the bank as possible. The terrestrial side was always somewhat lower than the spring side, which allowed salamanders to enter and leave at will. While it was possible for the salamanders to navigate in and out of the halved pipe, once they fled to the water, they would remain motionless in the bottom of the pipe and would not move unless disturbed. The plywood was then placed on the bank with enough overhang (18 cm) to cover the halved-pipe. After lifting the board in the same manner as used for coverboards, the inside of the pipe was examined for salamanders and, if present, the salamanders could be lifted out of the water while still in the pipe and then could be handled one at time while the others remained in the pipe. The space under the pipe was also checked either by sight or, for best results, by using the PVC halve in place to scoop out anything underneath it. Time and money invested into each trap were estimated by creating a sum of all steps and parts associated with the trap type (cutting boards, constructing half pipes, material prices, etc.).

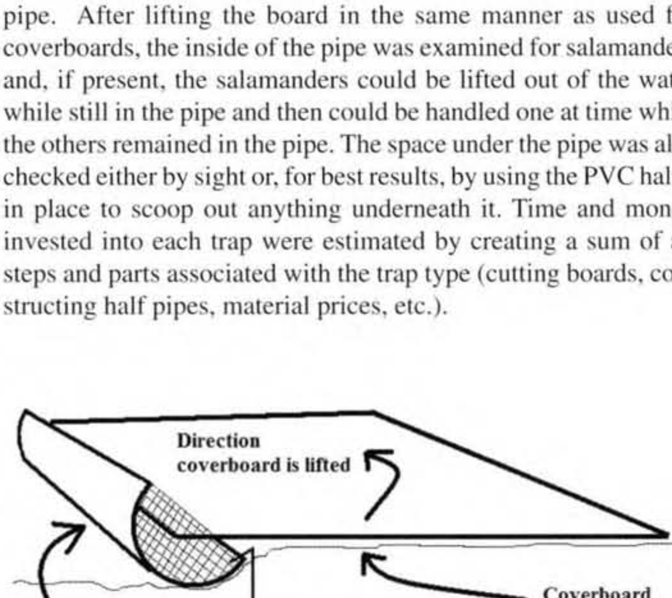

FIG. 1. PC trap as used in a spring at the study site.

TABLE 1. Total trap captures of each species and totals for each trap type. Surveys were conducted daily from 24 December 2003 to 3 January 3 2004, and on 1 February 2004 and 8 March 2004.

Species	PVC	Coverboard	PC traps	Total
Larval *Pseudotriton ruber*	6	16	59	81
Adult *Pseudotriton ruber*	0	3	2	5
Eurycea guttolineata	0	1	1	2
Eurycea cirrigera	0	2	3	5
Desmognathus conanti	0	5	0	5
Desmognathus auriculatus	1	1	3	5
Eurycea spp. Larvae	0	2	5	7
Totals	7	30	73	110

All traps were set on 22 December 2003 and checked daily from 24 December 2003 to 3 January 2004 and then again on 1 February 2004 and 8 March 2004 for a total of 13 days. Traps were checked, in order, from array 20 to array 1. We recorded the number and developmental stage of each species of salamander seen. Prior to release at the site of capture, each salamander was given a temporary ID by toe clipping, to keep track of recapture levels and movements. The same data for captures resulting from lifting or rolling natural cover within 1 m of the spring were collected, and the location was marked with an orange utility flag bearing information on species, date and time, ID number, and developmental stage. Cover that had been lifted or rolled for surveying purposes was replaced as close to the original position as possible and was checked on each successive survey. All larval salamanders considered too small for toe clipping were captured, noted, and released.

At the conclusion of trapping, 121 salamanders had been marked and were recaptured 57 times for a total of 178 captures. Species captured were *Desmognathus auriculatus*, *D. conanti*, *Eurycea cirrigera*, *E. guttolineata*, and *Pseudotriton ruber*. Larval *P. ruber* were captured most frequently (Table 1). Total number of salamander captures for the PVC, coverboard, and PC traps were 7, 30, and 73, respectively.

Each step in construction was done all at once (wood cutting, pipe sawing, etc.) and was timed along with assemblage to estimate overall construction times (Table 2). We used a hacksaw to cut through the PVC, which added time onto PVC and PC traps. PVC was the least effective of the three types in terms of both time and money invested per capture. Coverboards were the most efficient in terms of construction time invested per capture. The most efficient trap in terms of money invested per capture was the PC trap. Recently metamorphed *Rana clamitans* (N = 9) hibernated under the coverboards and PC traps. Only one snake, a *Nerodia fasciata* under trap 17B on 8 March 2004 (ca. 24 cm SVL), was found during the survey as it occurred during the winter season when they were inactive. Small crayfishes under 15 mm were occasionally found under boards and halved pipes of traps closer to the springhead.

TABLE 2. Construction cost and time invested per trap and per capture.

	Construction Cost	Construction Time	Cost/ Capture	Time/ Capture (min)
PVC	2.39	4	$6.81	11.4
Coverboard	1.62	5	$1.07	3.3
PC Traps	3.22	15	$0.88	4.1

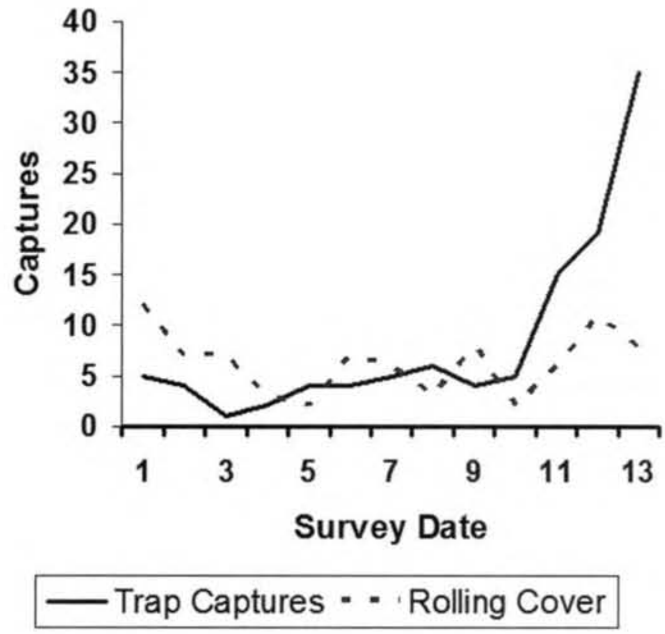

FIG. 2. Number of salamanders captured on each survey date (24 December 2003–3 January 2004, 1 February 2004 and 8 March 2004) resulting from trapping efforts and rolling natural cover present within 1 m of the spring.
